»Gewiß schadet es, -- abgesehen davon, daß es sündhaft ist,« behauptete die Sittsame, »hast du nie gehört, daß man nicht geheiratet wird, wenn man ein Verhältnis gehabt hat?«

»Ja, sie hat ganz recht; es bringt uns in Verruf,« half ihr eine zweite, »und der da würde euch gewiß nicht heiraten, bildet euch das ja nicht ein. Er kann euch ja auch gar nicht alle heiraten!« setzte sie schlagend hinzu.

Einzelne suchten zwischen den Streitenden zu vermitteln.

»Es ist doch alles nur Unsinn. Eine bloße Phantasiegeschichte. Also laß doch! Morgen in der Frühstückspause spielen wir mit verteilten Rollen weiter, dann ist wieder eine von uns der edle Unglückliche, und alle Gefahr ist vorbei.«

»Nein, nun ist es keine bloße Phantasiegeschichte mehr. Du hättest ihn uns nicht zeigen sollen, Ruth.«

Diese zuckte ungeduldig die Achseln.

»Das kann ich nicht ~so~ trennen. Wenn wir's spielen, leben wir's ja auch. Aber macht es doch, wie ihr wollt,« sagte sie zerstreut.

»Nein, erst mußt du es weiter ausdenken. Eigentlich ist es auch sehr lustig. Gerade als ob man zweimal lebt: einmal zu Hause und in der Schule -- und dann noch einmal ganz wo anders, wo alles gerade so ist, wie man es sich ausdenkt. -- Aber diesen Weg wollen wir lieber nicht wieder gehen.«

»Ach, seid ihr Feiglinge!« rief Wjera dazwischen, die sich bis jetzt am Streit nicht beteiligt hatte, weil sie sich noch mit dem »Unglücklichen« zu thun gemacht, der irgendwo an einer Straßenecke stehen geblieben war, »ich finde diese Geschichte tausendmal interessanter, als all die Phantastereien drum herum. Was hat man denn von denen? Sie amüsieren uns nur, weil man uns eingesperrt hält!«

Ueber ihrem Hin- und Herreden beachteten sie es gar nicht, daß sie an Ruths Wohnung am Isaaksplatz angelangt waren, das heißt, daß die meisten von ihnen sich recht beträchtlich von ihrem eigenen Heim entfernt hatten. Sie liefen gewohnheitsmäßig mit, wie eine Hammelherde, Ruth selbst aber war geradeswegs nach Hause gegangen. Jetzt blieb sie zaudernd stehen und kämpfte zwischen der Lust, nach einer Seitenstraße umzubiegen, und der Nötigung, zur gewöhnlichen Stunde bei ihren Verwandten einzutreten. Bis zu Tisch blieb noch viel Zeit, einen Vorwurf zog sie sich nicht zu, und was ihr jetzt vorschwebte, war süß und lockend gleich einem Frühlingsmärchen.

Aber es gab da etwas andres, das sie zurückhielt: wenn sie jetzt hineinging, so blieb sie, wie immer, gänzlich unbemerkt und unbeachtet im ganzen Hauswesen; wenn sie dagegen bis zum späten Mittagessen fortblieb, so wurde sie vielleicht bemerkt, befragt, belästigt. Und das entschied.

Wie eines jener kleinen Insekten, welche zum Schutz vor feindlichen Mächten die Farbe des Holzes oder des Laubes annehmen, auf dem sie sitzen, so verhielt sich, halb unbewußt, auch Ruth gegenüber ihrer Umgebung. Es war ihre Art sich zu wehren.

Ruth löste sich aus der schwatzenden Mädchengruppe und verschwand hinter den hohen Thürflügeln eines umfangreichen steinernen Gebäudes, vor dem ein Soldat Wache stand. Eine Abteilung des Kriegsministeriums lag darin, nebst mehreren großen Kronswohnungen, von denen Ruths Onkel, der Staatsrat war, eine inne hatte.

Ihr Verschwinden gab das Signal zum allgemeinen Aufbruch. Jetzt erst erschraken manche über die lange Versäumnis und suchten laufend eine Pferdebahnlinie zu erreichen oder unterhandelten mit den Droschkenkutschern, welche sofort, laut schreiend und sich gegenseitig nach Möglichkeit unterbietend, sie umringten.

Bis morgen vermißten sie Ruth nicht mehr; sie hatten sich ausgezeichnet unterhalten, sich ordentlich echauffiert! Morgen, wenn sie nach neuer Nahrung begierig wurden, kam sie wieder.

* * * * *

Erik war den Mädchen nur einen kleinen Teil des Weges gefolgt, denn er hatte noch in einem Knabengymnasium und in einer Privatschule Stunden zu geben. Dann ging er in seine Stadtwohnung hinauf, die geräumig und freundlich, aber vier Treppen hoch lag: dafür konnte man aus den Fenstern die Newa überschauen, durch deren blaue, mächtige Wogen noch der Ladogasee seine letzten Eisschollen trieb. Sie schimmerten durchsichtig im blendenden Maisonnenschein. Ueber seine Aussicht freute Erik sich täglich von neuem.

Nach Schulschluß pflegte er hier vorzusprechen, allerlei zu erledigen und eingelaufene Briefe mitzunehmen, denn die Landpost galt als unzuverlässig. Heute war er kaum eingetreten, als es klingelte.

Er öffnete die Thüre und blieb mit einem Lächeln neben derselben stehen.

»Warwara Michailowna!« sagte er.

»Was ist denn das?« fragte sie, rasch um sich blickend, »schon auf dem Lande? umgezogen? allein hier? Ich wußte es nicht! Dann haben Sie also meinen Brief -- --?«

»Ich habe ihn gestern hier vorgefunden,« versetzte er, sie in die angrenzende Wohnstube führend, wo die Polstermöbel schon ihre Sommertoilette empfangen hatten und in ihren weißen Leinwandhülsen gleich Gespenstern herumstanden. Unter dem runden Sofatisch war der Teppich entfernt worden, und ein leichter Geruch von Kampfer schwebte in der Luft.

»Ich wollte mir Ihre Antwort lieber selbst bei Ihnen holen -- oder bei Ihrer Frau!« sagte Warwara Michailowna und ließ sich in einen der weißbezogenen Sessel sinken, »trotz Staub und Sonne bin ich also da. Ich muß wissen, weshalb Sie nicht kommen wollen.«

Sie sah wunderhübsch aus in der gewählten Einfachheit ihrer Frühjahrskleidung, mit ihrem reizenden Mund und mit der Melancholie in den tiefdunkeln Augen, die einen so pikanten Gegensatz zu ihrem munteren Wesen bildete.

»Ich danke Ihnen!« erwiderte Erik und blickte sie an, »aber Sie nehmen mir in der That die Antwort schon von den Lippen: ich wollte wirklich nicht kommen. Mich eine Zeit lang ganz auf dem Lande vergraben. -- Dort können wir ja, wenn Sie erst hinausgezogen sind, so poetisch Fangball spielen und Croquet. -- Ich bin diesen Winter gar zu stark ins Gesellschaftstreiben geraten.«

»Und was schadet das? Fragen Sie nur Klare-Bel, ob sie Sie nicht auch im Gesellschaftsrock am liebsten sieht? Der Salon ist Ihr natürliches +milieu+. Sie sind nun einmal kein solcher deutscher Bär und Philister, wie sie mitunter mit goldenen Brillen und blonden Vollbärten zu uns kommen! Erst seit einigen Generationen hat sich Ihre Familie dort niedergelassen -- an der friesischen Grenze irgendwo, -- französische Emigranten, -- weiß ich's nicht gut?«

»So weit wollen Sie den Beweis herholen, daß ich in Gesellschaft gehen soll?«

Sie lachte und stieß belustigt den Elfenbeingriff ihres Sonnenschirms gegen die Tischplatte.

»Sie sind ein Spötter. Ich wollte nur sagen: bilden Sie sich nicht ein, daß Sie zum Schulmeister geboren sind. Trotz der blauen Uniform da, die Sie noch anbehalten haben, -- die Ihnen übrigens gut steht, weil es ein Frack ist. Sie sind zum Weltmann geboren. Wenn Sie uns -- +mondains+ -- meiden, thun Sie sich selbst weh. -- -- Ich weiß es. Lachen Sie nicht.«

»Ich lache ja nicht. Sie sind sehr scharfsichtig, Warwara Michailowna. -- Vielleicht zu sehr.«

Sie schüttelte den Kopf.

»Sie würden unsrer verwöhnten Gesellschaft nicht so gut gefallen, wenn Sie nicht selbst ein wenig von ihr berauscht würden. Habe ich nicht recht?«

»Nun, nehmen wir also an, ich will nicht berauscht werden,« sagte Erik und kreuzte die Arme; »daß gerade Sie als Versucherin kommen, ist freilich schlimm für mich. Ein Glück, daß die Saison zu Ende geht.«

Sie machte einen schmollenden Mund.

»Ich weiß schon. Mich halten Sie für die Inkarnation weltlicher Oberflächlichkeit.«

Er widersprach nicht.

Einige Augenblicke lang schwiegen sie beide, und zwischen ihnen lag, unmöglich zu überhören, Warwaras stumme Frage: »Bin ich es, die dich berauscht?«

»Sie sind ein Egoist,« sagte sie dann aufblickend, »sonst hätten Sie bemerken müssen, daß Sie sich irren. Wissen Sie nicht, weshalb ich Sie so gern da habe, mitten unter den Menschen? Weil ich gerade ebensogut fühle wie Sie, daß dieses Treiben im Grunde eitel und hohl ist, -- inhaltsleer, -- und es mich dennoch berauscht -- wie Sie. Ihre Anwesenheit war also die eines Leidensgenossen für mich. Hand aufs Herz! sind wir nicht so etwas wie Leidensgenossen? Wir haben eine gemeinsame Versuchung.«

Er blickte sie fest an. Sie sprach rasch, ein wenig erregt, mit dem weichen, klingenden Tonfall, den er an den Slaven so einschmeichelnd fand. Ihr selbst war es in diesem Augenblick nicht ganz klar, ob sie mit ihm kokettierte, oder ob sie nicht vielleicht ehrlicher mit ihm sprach, als je mit sich allein. Es schien ihr wirklich manchmal -- und besonders in den seltenen Stunden des Alleinseins, -- als triebe ein verwandter Zug sie zu einander. Und dann war ihr Erik interessant: als Mensch. So, wie unter lauter Satten ein Hungriger interessant ist. Unter den Gesellschaftsmenschen ihrer Umgebung kam er ihr vor wie einer, der ungeduldig auf Beute ausgeht, und, weil er die ihm gemäße dort nicht findet, seinen Hunger mit Naschwerk zu betäuben sucht.

»Also: Kameradschaft in einer gemeinsamen Versuchung!« sagte Erik wegblickend -- »vielleicht ein Wettkampf, wer ihr besser erliegt?«

Sie erhob sich, um zu gehen.

»Sie haben vielleicht recht zu spotten, und es würde nur sentimental klingen, wenn ich antworten wollte: nein! mehr als das, -- eine gemeinsame Sehnsucht,« entgegnete sie, dicht neben ihm, der ebenfalls aufgestanden war, »Sie haben tausendmal recht. Wir haben ja nie ein ernstes Wort miteinander gesprochen. Und ein Mann braucht keinen Bundesgenossen. Er kann's allein.«

Sie sprach ganz ernst, es klang beinahe echt, und was sie sprach, stimmte so eigentümlich zu der Schwermut der dunkeln Augen. Eine Minute, -- eine verschwindende Minute lang, fühlte Erik, wie seine Phantasie ihm etwas vorgaukelte. Eine Sehnsucht brach heiß in ihm auf, über die der Verstand lachte, -- und ein wilder, herrischer Wunsch, den lachenden Verstand unter die Füße zu treten und einen schönen Selbstbetrug wahr zu machen.

Ohne genau zu wissen, was er that, hatte er die Hand ausgestreut; es war eine fast befehlende Bewegung, wie ein: »Bleib!« Er sah nichts mehr deutlich, er empfand nur die Nähe dieser schmiegsamen Gestalt, dieser Augen, von denen Sehnsucht ausging.

Und plötzlich küßte er sie mit geschlossenen Augen auf den Hals und die Wange. Nicht tändelnd, versuchend. Rasch, heftig, fast gewaltthätig.

Er murmelte halb unverständlich: »Mach es wahr! mach es wahr! laß mich nicht aufwachen! Suchtest du mich?«

Bei seinen bewußtlosen Küssen überfiel Warwara ein plötzlicher Schreck. Sie war selbst berauscht gewesen, einen Augenblick lang, aber die Wucht, mit welcher er darauf einging, ernüchterte sie ebenso rasch. Durch die momentane Erregung seiner Sinne hindurch spürte sie etwas von dem tiefinnersten Hunger und der Sehnsucht in ihm, an die sie unvorsichtig gerührt hatte. Nicht wie eine Dreistigkeit die erstaunt oder verletzt, empfand sie seinen Kuß, sondern wie eine lähmende Gefahr für Leib und Seele, die zu verschlingen droht, was ihr zu nahe gekommen ist.

Mit einer heftigen Bewegung hatte sie sich freigemacht.

Ihr Blick lief über ihn hin. Eigentlich sollte er ihr wie ein Kind vorkommen, das so erfüllt ist von Lebensverlangen und ungeduldiger Erwartung, daß es nicht mehr zu spielen vermag. Es zerbricht gewaltsam das dargebotene Spielzeug, um zu sehen, was dahinter ist, und bleibt mit enttäuschtem Gesicht stehen.

Das wollte sie nicht. Lieber noch gespielt haben, als zu ernst genommen werden, -- so ernst, daß ihr Inneres bloßgelegt und an unmöglichen Illusionen gemessen würde. Sie fürchtete sich vor dem enttäuschten Gesicht.

Erik mißverstand die Heftigkeit ihrer Bewegung. Aber sie weckte auch ihn. Er hatte ja nur einen Augenblick vergessen, daß sie spielte. -- Seine Erregung verflog sofort. Nur etwas Spott blieb in den Augen und um den Mund zurück. Spott über sich selbst.

Die Luft im Zimmer war zum Ersticken schwül. Fast ungehindert schien die Sonne durch die dünnen, weißen Fenstervorhänge, und mißtönend klang von der Straße der Lärm der Droschken und Pferdebahnen herauf.

Warwara war langsam in den Vorflur gegangen, und Erik geleitete sie an die Hausthür. Sie wechselten kein Wort miteinander.

Erst an der Thür wandte sie sich um zu ihm und maß ihn mit einem sonderbaren Blick, den er nicht verstand. Bedauern lag darin, aber auch Ablehnung, eine kleine Ueberlegenheit über ihn, den Mann, und dann noch etwas, wie ein ganz leises Eingeständnis: »Ich möchte wohl die sein, die du brauchst, und die dich sättigen könnte, du Wilder. Aber ich bin's nicht.«

»Ich nehme an: Sie kommen nicht,« bemerkte sie dabei zerstreut.

»Mit Ihrer Erlaubnis: nein!« entgegnete er, und sann dem Blick nach.

Die Thür fiel ins Schloß. --

* * * * *

Ruth war pünktlich um vier Uhr, zur festgesetzten Mittagsstunde, im Speisesaal erschienen, der, hoch und groß, mit dunkeln Mahagonimöbeln ausgestattet, in der Mitte einer Flucht von Gemächern lag. Sie hatte ihren äußern Menschen so glatt gebürstet und gestriegelt, wie der Onkel, die Tante und die Cousine sich zu tragen pflegten, und saß schweigsam auf ihrem Platz am Tisch, den ein Diener in weißbaumwollenen Handschuhen geräuschlos bediente. Während des Essens, das die Beteiligten in ausgiebigster Weise beschäftigte, blieb die Unterhaltung recht einsilbig. Der Onkel liebte keine langen Tischgespräche, und seine Frau hatte genug damit zu thun, ihn mit den richtigen Stücken zu versorgen.

Erst als die Mundspüler von grünem Glas, die kein Mensch benutzte, vor jeden einzelnen niedergesetzt waren, und vor der Tante die silberne Kaffeemaschine stand, auf der sie den Kaffee immer eigenhändig bereitete, wurde es ein wenig lebhafter bei Tisch. Darauf schien Ruth nur gewartet zu haben. Sie erhob sich leise von ihrem Sitz und wollte verschwinden.

»Gehst du schon auf dein Zimmer, mein Kind?« fragte die Tante, »dann sieh dich mal darin um. So unordentlich, so wenig zierlich sollte es bei keinem jungen Mädchen im Zimmer aussehen.«

Ruth machte eine Armesündermiene. »Ich will wunderschön aufräumen,« sagte sie eilig; »darf ich dann bis zum Thee noch einmal fortgehn?«

»Bis zum Thee? Ist es denn etwas so Dringendes?«

»Es ist etwas Dringendes,« sagte Ruth. Der Onkel sah auf.

»Zu wem willst du denn gehn? Es ist wohl jemand aus der Schule?«

»Ja,« erklärte Ruth und rieb ungeduldig den Thürgriff, den sie schon in der Hand hielt.

»Sage dem Diener, daß er dich begleitet und dort auf dich wartet.«

Der Onkel blickte ihr nach, wie sie leise die Thür hinter sich schloß.

»Ein merkwürdig bequemes Ding ist sie doch,« meinte er dann, seine Cigarette anzündend, »ich kenne niemand, der weniger verlangt und sich weniger bemerkbar macht als sie.«

»Weil man ihr alles gewährt,« ergänzte die Tante mit ihrer etwas hohen Stimme, die den baltischen Accent noch unangenehmer hervortreten ließ. Sie war eine Baronesse aus Livland.

»Alles? nun weißt du, ein andres Kind würde nicht so zurückhaltend sein. Sie weiß zum Beispiel: dies ist die Stunde des intimsten, ungestörtesten Beisammenseins, -- und immer geht sie fort. Aber mit knapp sechzehn Jahren handelt man doch nicht aus Takt.«

»Nein, das thut sie auch nicht. Du idealisierst Ruth immer. Sie liebt uns einfach nicht genug, um sich enger an uns zu schließen. Manchmal denke ich: sie ist vielleicht herzlos.«

»Aber Mathilde! wie kannst du dem kleinen Ding etwas so Böses nachsagen! Lies mal den letzten Brief aus Belgien, wie sie sie da in der Pension loben und zurückverlangen.«

»Ja, das kennt man, mein Lieber. Sie war ein einträglicher Pensionär. Und dann sind sie dort katholisch. Wie kann man ihnen trauen? Ich bin es gerade, die deswegen für Ruths Uebersiedlung zu uns gewesen ist. Wir sind doch schließlich verantwortlich für sie. Dafür, daß sie in Zucht und Ordnung aufwächst. Was hat man davon, daß ihre Verwandten dort von vlämischem Adel sind? Die Ansichten sind doch die Hauptsache. Und die Leute dort kennt man nach der Richtung gar nicht.«

Der Onkel schwieg mit verdrießlichem Gesicht. Er wußte, daß für seine Frau alle Menschen außerhalb der kleinen baltischen Provinzen »diese Leute« waren, -- während für ihn, gerade umgekehrt, die Welt erst jenseits der russischen Grenze anfing. Ihm kam nicht nur die beschränkte provinzielle Exklusivität seiner Frau lächerlich vor, sondern sogar auch ihr baltisches Heimatsgefühl. Mit seinem französischen Namen und den sowohl deutschen wie slavischen Elementen in seiner Familie fühlte er sich dermaßen als Kosmopolit, daß er nie eine Gemütsbeziehung zu irgend einem Lande und Volke besessen hatte. Er schalt und klagte nur deshalb nicht über Rußland, wie die meisten seinesgleichen, weil er dies für unvornehm hielt.

»Ruth würde jetzt gewiß nicht von hier fortgehen mögen, Mama,« bemerkte die Tochter, »jetzt, wo sie so gut wie erwachsen ist. Nirgends kann man doch so gut in die Welt geführt werden wie hier.«

»Aber mir scheint, das will sie gar nicht,« versetzte der Onkel lächelnd, der seine hübsche Tochter sehr gern in Gesellschaften begleitete, »sie hat ja ohnehin so viel Welt und Menschen gesehn und macht sich nichts daraus. Gott sei Dank also, daß wir mit ihr nicht noch einmal dieselben Umstände haben werden, wie seit einem Jahre mit dir, Liuba.«

»Nun bist du wahrhaftig im stande und setzest dein eigenes Kind für Ruth herab,« sagte seine Frau nervös, die kein Gehör für einen scherzenden Ton besaß, »laß sie doch nur in Gottes Namen nach Belgien reisen!«

»Nein!« entgegnete er ärgerlich, drehte seinen Stuhl vom Tisch ab, ergriff eine Zeitung und vergrub sich hinein. Als eine der unangenehmsten Eigenschaften an seiner Frau war ihm stets ihre unleugbare Vortrefflichkeit erschienen, gegen die es niemals einen Appell gab, aber beinahe noch unangenehmer erschien ihm dieser gänzliche Mangel an Humor.

Die Stunde des »intimsten, ungestörtesten Beisammenseins« war gründlich verdorben. --

Ruth freilich ahnte nicht, daß sie von ihrem leeren Platz am Tisch den unschuldigen Störenfried spielte, ja, sie hatte im Augenblick vielleicht fast vergessen, in welchem Lande der Erde, ob in Belgien oder Rußland oder Deutschland oder sonstwo sie sich befinde. Die Hände auf dem Rücken verschränkt, den Kopf ein wenig gesenkt, ging sie rastlos in ihrer Stube auf und ab, und dabei trug ihr Gesicht den Ausdruck angestrengtesten Nachdenkens, wie vorhin auf der Schulbank während des Unterrichts. Ihre Wangen waren heiß und lebhaft gerötet, und von Zeit zu Zeit schüttelte sie den Kopf, als könne sie mir ihren Gedanken nicht recht ins reine kommen.

Nach einer Weile blieb sie stehen, strich sich das Haar aus der Stirn und entsann sich ihres Versprechens, »wunderschön aufzuräumen«. Damit ging es außerordentlich rasch. Jedes einzelne Ding, das herumlag, wurde in die ihm zunächstgelegene Schublade befördert, und als dies gewissenhaft geschehen war, zeigte es sich, daß im Zimmer verblüffend wenig Gegenstände übrig geblieben waren, die man nach der Vorschrift der Tante »zierlich« hätte ordnen können. Es war ein ganz wohnliches kleines Zimmer, mit hübschen Möbeln, einem rotsamtenen Ecksofa und sogar einer Nippesetagère, auf der ein gläserner Mops stand. Aber es trug nicht das Gepräge seiner Besitzerin, sondern das einer gut eingerichteten Hotelstube. Weder Arbeiten noch Liebhabereien plauderten etwas über das Wesen derjenigen aus, die hier schlief und lernte und träumte. Es hatte den Anschein, als sage Ruth täglich auch zu dieser Umgebung, wie vorhin in der Schule: »Ich gehe doch bald fort.«

Als Ruth fertig war, griff sie hastig nach einem weichen englischen Wollbarett von leichter grauer Strickerei, setzte es wie eine Knabenmütze auf den Kopf und rief den Diener aus der Dienerstube neben der Küche. Dieser saß in seinem geblümten Zitzhemde, die Messer putzend, rittlings auf einer Bank und sang dazu, so daß die Messer im Takte flogen. Es war ein junger Tatar, sehr gewandt und, als Mohammedaner, musterhaft nüchtern. Beten, singen und schlafen waren seine liebsten Beschäftigungen. Wie er Ruth rufen hörte, schlüpfte er eilig in seine dunkle Livree und öffnete ihr die Hausthür.

Sie ließ sich von ihm bis zum finnländischen Bahnhof begleiten; dort entließ sie ihn.

»Jetzt kannst du zu deinen Bekannten gehn, Basil,« sagte sie zu ihm, als er mit gezogenem Hut an der Waggonthür stand, »aber um neun Uhr mußt du mich hier wieder erwarten.«

Er nickte verständnisvoll mit dem kurzgeschorenen Kopf, der oben eine kreisrunde, glatt ausrasierte Stelle zeigte, sah aber dabei seine kleine Herrin etwas besorgt an. Er wollte gern zu »seinen Bekannten« gehn, aber unerhört kam es ihm vor, sie so schutzlos in die weite Welt hinauffahren zu lassen, namentlich gegen Abend, wo es so viele Betrunkene auf den Straßen gab.

»Dürfte ich nicht um die Erlaubnis bitten, mitzufahren?« fragte er und kämpfte mit dem heroischen Entschluß, freiwillig aus sein Vergnügen zu verzichten.

Ruth lachte über sein pfiffiges Tatarengesicht, das eben jetzt fast treuherzig aussah, und schüttelte den Kopf.

»Wo ich jetzt hingehe, darf niemand mitgehen!« sagte sie feierlich.

Während der Fahrt blickte sie ungeduldig hinaus, wie eine, die froh ist, alles hinter sich zu lassen; die kurze Strecke kam ihr lang vor, als führe sie wirklich weit -- weit, in eine ganz andre Welt. Aber als sie dann am kleinen Stationsgebäude ausstieg und sich nach dem richtigen Wege durchfragen mußte, da wurde ihr bänglich zu Mut. Was ihr vorgeschwebt hatte, -- zwingend, unwiderstehlich, -- war ein ganz bestimmtes Traumbild, und solange nur ihre Phantasie daran herummalte, schien alles sich ihr von

selbst zu verwirklichen. Das Wirklichkeitsbild aber, das ihr jetzt fremd entgegentrat und in den Traum eingriff, verschüchterte sie; es wäre eigentlich schöner gewesen, wenn alles sich auch noch weiter so von innen heraus geformt hätte, wie man es sich eben träumen läßt.

Die bange Empfindung nahm nicht ab, sondern zu, wie sie endlich dem Hause nahe kam, das sie suchte. Es war ihr, als erwache sie plötzlich und befinde sich todesallein in wildfremder Gegend. Eine förmliche Angst überfiel sie vor lauter Schüchternheit und wie gelähmt blieb sie am Gartengitter stehen.

Da lag das Haus vor ihr; eine Magd fegte auf dem breiten Kiesweg vorn die Strohhalme zusammen, die bis auf die Straße verstreut waren, und daneben stand ein Knabe, den Hut im Nacken, und sah zu. Der mußte sie sicher gleich bemerken. Am liebsten wäre sie wieder umgekehrt.

»Die Augen zumachen -- fortlaufen!« dachte sie sehnsüchtig. Aber das durfte sie nicht. Ihren eigenen Willen durfte sie ganz gewiß nicht hinterdrein im Stich lassen.

Da sang eine Nachtigall im Fliedergebüsch am Zaun.

Und leise -- leise, mit werbendem Klang, lockte aus der Tiefe des Gartens die zweite.

Ruths Augen schweiften am Hause vorbei über den Garten und blieben entzückt darauf haften.

»Der Frühling!« sagte sie jauchzend, ganz laut.

Sie hatte ihn noch gar nicht gesehen in diesem Jahr. Nun erst ward sie sich dessen bewußt, daß sie doch soeben, auf dem Wege vom Bahnhof, unter grünenden Birken gegangen war, und daß im Grase am Wegrand weiße Anemonen standen. Jetzt kam es ihr vor, als sei das nur so ein wenig Frühling gewesen, der von den Menschen, die aus diesem Garten traten, unterwegs verstreut wurde. Aber hier war der Frühling zu Haus, von hier mußte er kommen; und nun stand sie dicht am Gitter, hinter welchem er blühte. In dem rotgoldenen Duft, den die Sonne darum wob, schaute er mit der eben aufbrechenden Obstblüte und dem zarten Laub der Bäume wie ein Märchen hinter dem alten Hause hervor. Da einzutreten, das war fast, als ob man aus einem Traum gar nicht herauskam.

Jonas hatte sich neugierig der Gartenpforte genähert, an der jemand stand, von dem er nicht recht wußte, ob es ein Mädchen sei.

»Ich möchte hier herein!« sagte Ruth bittend. --

Erik und Klare-Bel saßen an dem noch nicht abgedeckten Mittagstisch im Wohnzimmer an der Terrasse, und wie immer erzählte Erik seiner Frau lebhaft und mitteilsam von den kleinen Begebenheiten des Tages. Voll Humor schilderte er ihr die Mädchenschule und Ruth. Warwaras Besuch in der Stadtwohnung erwähnte er nur flüchtig.

Da kam Jonas atemlos ins Zimmer gestürzt. »Papa! da ist jemand, der dich sprechen will. Ruth heißt sie. Ich habe sie in dein Arbeitszimmer geführt.«

»Aber Jonas!« rief seine Mutter, »wie konntest du das nur thun! Da drin muß es ja noch schauderhaft aussehen! Bringe sie doch herüber, Erik! bitte, bringe sie lieber herüber! Wenn Gonne nur abräumen möchte!«

Erik hörte es nicht mehr. Er war schon fort.

Als er raschen Schrittes über den Flur in sein Zimmer trat, stand Ruth mitten in demselben, etwas vornübergeneigt und die Hände fest gegen die Brust gedrückt. Der erste Eindruck, den er empfing, war wieder der des Scheuen, Vereinsamten, wie in dem Augenblick, wo sie so still gesagt hatte: »Mir hilft niemand!« Wie er sie so dastehen sah und sie ihm mit großen, bangen Augen entgegenblickte, erinnerte sie in keinem Zuge mehr an den ausgelassenen Jungen im Schulhof.

Erik kam nur undeutlich die Vorstellung davon, daß man im Fall eines unerwarteten Besuches zunächst einen Stuhl anbietet und irgend etwas Freundliches sagt. All dies Gethue kam ihm wie zu einer andern Welt gehörig vor, -- jedes konventionelle Wort vergaß er dieser schüchternen, kindlichen, sichtlich aufs tiefste ergriffenen Gestalt gegenüber. Es war, als stände sie auf einer einsamen Insel, am weiten Meeresstrande, ganz allein vor ihm -- ein Kind aus dem Volke -- und ringsum nichts als ein paar schwebende Möwen über ihren Köpfen.

Ganz unwillkürlich, aus diesem Eindruck heraus, fand er nur das Wort der Freude: »Kommst du zu mir?«

Das »Du« wirkte wie eine Erlösung auf sie. Es schien ihr in dieser Einfachheit ein Zauberwort, das die fremde, herzbeklemmende Wirklichkeit mit einem Schlage verwandelte, -- sie umwandelte zur traumhaften Verwirklichung dessen, was Ruth ersehnt und ersonnen hatte.

Sie machte einen Schritt auf Erik zu, ein heller Ausdruck flog über ihr ganzes Gesicht, und die Hände fester gegen die Brust pressend, deren Herzklopfen ihr den Atem benahm, sagte sie kindlich: »Danke!«

Er hatte sich auf einen der umherstehenden Stühle gesetzt und faßte ihre Hände in den seinen zusammen. Die Hände zitterten, und es fiel ihm auf, wie blaß und schmächtig sie aussah, wenn nicht der Ausdruck übermütiger Lebenslust, den er an ihr gesehen, darüber wegtäuschte.

»Fürchtest du dich?« fragte er, und sein Blick ruhte aus dem schmalen Gesichtchen.

Sie nickte ganz leise mit dem Kopfe, und noch immer zitterte sie, wie ein Vogel, auf den eine fremde Hand sich legt.

»Du fürchtest dich doch nicht vor mir, zu dem du kamst? Sage mir, weshalb du kamst.«

Sie nahm ihre Mütze vom Kopf und besann sich. In Gedanken durchlief sie die ganze Entstehungsgeschichte ihres Entschlusses, vom ersten Schuleindruck an, -- aber die ließ sich ja, so weitläufig und verworren wie sie war, ganz gewiß nicht wiedererzählen. Sie versuchte, die Hauptsache herauszuholen. Aber nun vergaß sie alles. Es war rein unmöglich.

Und plötzlich brach Ruth in Thränen aus.

»Mein liebes Kind!« sagte er sanft, und strich ihr das lose, lockige Haar aus der Stirn, das über das gesenkte Gesicht gefallen war. Dann nahm er ihre Hände wieder in die seinen.

»Hast du Vertrauen zu mir?« fragte er.

»Ja!« sagte sie leise.

»Unbedingtes?«

»Ja!« sagte sie wieder.

»Dann darfst du weder zittern noch dich fürchten. Versuche jetzt einmal ganz fest, es zu bezwingen. Ganz fest, hörst du? Es wird schon gehn.«

Sie machte eine Anstrengung, das nervöse Beben, das durch ihren Körper ging, zu unterdrücken. Er wartete ruhig einige Augenblicke, bis es ihr gelungen war. Dann beharrte er auf seiner ersten Frage: »So. Und nun sage mir, weshalb du kamst. Sage es, so gut du kannst. Versuche es nur. Ich werde dir helfen.«

Sie seufzte und begann unsicher. »Ich komme nun bald nicht mehr in die Schule --«

»Nein. Ich weiß. Und --?«

»Und da mußte ich hierher.«

Sie brach ab, wie um ihre Gedanken zu ordnen, dann fügte sie schüchtern hinzu, mit einem rührenden Ausdruck: »Ich bin ja allein!«

Erik wurde es warm bis ins innerste Herz. Nie noch meinte er eine so tiefe, so heilige Zärtlichkeit empfunden zu haben, wie diesem Kinde gegenüber. Der Wunsch, sich ihr zu widmen, die Hand auf sie zu legen, wie auf etwas, das ihm zugehörte, ward plötzlich so stark in ihm, daß er ihn unwillkürlich als bereits erfüllt nahm und kein Hindernis gelten ließ.

»Möchtest du hierher gehören, Ruth?« fragte er.

»Ach ja!« rief sie lebhaft, und dann sagte sie mit Inbrunst: »Immer!«

Ihr Gesicht hatte sich verändert, die Augen sahen jetzt ganz dunkel aus und lachten aus den nassen Wimpern. Sie hätte so gern wieder gesagte »Danke!« Denn es lag der Inbegriff all ihres Denkens und Fühlens in dem Worte ausgesprochen. Aber sie scheute sich, es zu wiederholen.

Erik sah ernsthaft vor sich nieder, als erwäge er nachdenklich einen Plan.

»Nach dem Verlassen der Schule würdest du wohl noch mancherlei Unterricht erhalten,« bemerkte er, sie zur Wirklichkeit zurückführend, »wenigstens wäre das in hohem Grade wünschenswert. Möchtest du ihn bei mir nehmen?«

Sie nickte eifrig.

»Gut. Wir würden also miteinander arbeiten,« -- und in leichtem Tone setzte er hinzu: »sehr viel arbeiten, Ruth! Wirst du das auch wollen? In dem Aufsatz da, -- der hat uns ja zu einander geführt, nicht wahr? -- nun, da steht fast ebensoviel zum Erschrecken wie zum Freuen. Einen so ungeordneten kleinen Kopf, mit so krausen, wilden, unfertigen Einfällen und Vorstellungen habe ich noch gar nicht gesehen. Glaubst du das wohl?«

Sie lächelte nur und sah ihn vertrauensvoll an, als ob sie dächte: »Du wirst es schon ordnen und entwirren!«

Er blickte schweigend auf sie hin, und wieder erschien sie ihm wie ein scheuer, kleiner, mattgeflogener Vogel, der sich hilflos verflattert hat, und sich mit einemmal in einemn weichen Neste findet.

Draußen zögerte die Maisonne am Himmel, und durch den feinen Nebel hindurch, der von den feuchten Wiesen jenseits des Gartens aufstieg, fielen ihre Strahlen beinahe rot, wie flüssiger Purpur. Die beiden noch vorhanglosen Fenster gingen direkt auf den Hintergarten hinaus.

Ein herber, frischer Duft nach Birkenknospen wehte mit dem lauen Abendwind ins Zimmer, und unermüdlich tönte das inbrünstige Locken der Nachtigallen.

Während Erik auf Ruth schaute, kam ihm eine störende Erinnerung.

»Erzähle mir doch,« sagte er unerwartet, »was denn das für ein Mann war, den du auf der Straße grüßtest?«

Sie errötete etwas und wurde verlegen, aber um ihre Mundwinkel zuckte es dabei, wie von verhaltenem Mutwillen. Auf den Wangen erschienen verräterisch zwei Schelmengrübchen.

»Ich -- -- -- ach, der! Den kenne ich ja gar nicht.«

»Aber er sah dich doch so an, als ob ihr euch recht gut kenntet. Wie kam denn das?«

»Ja, das kam so,« begann sie mit einem Seufzer, und überlegte, »-- es ist wirklich nicht leicht zu erzählen. Ich habe ihn mir ausgesucht, aber er weiß ja nichts davon.«

»Ausgesucht? Aber, liebes Kind, das kann doch kein Mensch verstehen,« sagte er ungeduldig, »nimm dich besser zusammen, Ruth! sprich deutlicher. -- Nun?«

»Ich will ja!« rief sie eingeschüchtert, »es ist bloß so schwer! Es war eine bloße Geschichte, -- die wir untereinander spielten, -- im Schulhof, in der Frühstückspause, -- und da mußte jemand vorkommen, der ungefähr so aussah. Und da -- habe ich mir diesen ausgesucht, weil es schöner geht, wenn man dabei an einen lebendigen Menschen denkt.«

»Aber was sollte er denn davon denken? Zum Beispiel schon davon, daß du ihn zuerst grüßtest?«

»Das mußte ich ja thun! Wie sollte er sonst wissen, was er zu thun hatte? Ob er grüßen durfte?«

»Und wenn er nun auf der Straße mit dir angebunden hätte? Hast du denn das nicht überlegt?«

Sie sah erstaunt auf.

»Das durfte er ja gar nicht. Das hätte gar nicht in seine Rolle gepaßt. Er mußte edel und unglücklich sein.«

Erik entfuhr ein kurzer Laut. Seine Augen blickten ernst, fast besorgt auf sie.

»In eurem kindischen Spiel -- ja. Aber in der Wirklichkeit?« fragte er langsam. »Kannst du deine Gedanken nicht besser in Zucht nehmen? Kannst du das nicht auseinander halten? Das mußt du können, Ruth! Und nun sage mir, was du gethan hättest, wenn er aus der eingebildeten Rolle gefallen wäre?«

Sie dachte nach.

»Dann hätte ich die Augen zugemacht und wäre fortgelaufen.«

»Wärst du denn dadurch unsichtbar geworden, daß du die Augen zumachst?«

»Ich? Nein! aber doch er. Denn dann hätte ich ja einen andern suchen müssen.«

»Einen andern?!«

Sie nickte.

»Es gibt ihrer viele!« versicherte sie treuherzig.

»Und das hättest du wirklich gethan? Besinne dich mal! Wäre es dir wirklich auch dann noch nicht klar geworden, wie kindisch und dreist dein Benehmen war?«

Ruth sah unglücklich aus. Offenbar machte er ihr einen Vorwurf. Sie dachte nach, was er nur damit meinen könnte? Sie konnte nicht begreifen, was dieser fremde Mann, außerhalb seiner Rolle, sie kümmern sollte?

»Ich brauchte ihn, und da nahm ich ihn mir!« rief sie mit kläglichem Gesicht.

Erik stand auf und ging ein paarmal durchs Zimmer. Dann blieb er vor Ruth stehen, die sich auf die Kante seines Stuhles gesetzt hatte.

»Sage mir, gibt es mehr solcher fremder Menschen, die du auf der Straße grüßest?«

»Ja. Alle Straßen sind voll davon.«

»-- Männer --?« fragte er zögernd.

»Auch Männer. Ich brauche immer frische für die Schule. Auch Frauen, Kinder, alte Leute.«

»Was meinst du damit, daß du Männer ›für die Schule‹ brauchst?«

»In den Geschichten für die Mädchen muß immer einer vorkommen. Am liebsten einer mit einem kleinen Schnurrbart. Aber ich habe auch andre Geschichten, -- viel, viel schönere, -- wunderschöne,« fügte sie lebhaft hinzu, -- »und die mit Kindern sind nur die liebsten.«

»Erzählst du die den Mädchen in der Schule nicht?«

Sie schüttelte den Kopf.

»Sie finden sie nicht schön!« sagte Ruth traurig.

Er setzte sich zu ihr auf einen Ledersessel, der am Fenster stand, und neigte sich ein wenig vor.

»Willst du sie künftig mir erzählen?« fragte er ernst, »aber alle, ohne eine Ausnahme. Und ohne einen Winkel, in den ich nicht hineinsehen könnte. Ich muß alles wissen und hören, was durch diesen phantastischen, unnützen Kopf geht. Wir wollen einen ordentlichen Vertrag machen: du sollst sie auch niemand sonst mehr erzählen. Nur mir. Immer, mit allem hierher kommen. Du wolltest ja hierher gehören. -- Wirst du es bedingungslos und gehorsam thun?«

Ihre Augen waren groß und dankerfüllt auf ihn gerichtet; er konnte es an ihrem Gesicht sehen, wie die Gedanken in ihr vergebens nach Ausdruck rangen, aber er hatte dennoch keine Ahnung davon, mit welch einem innern Jubel ein neues Glück ihr aufging. Sie wollte es ihm so gern sagen, aber in ihrem wortarmen Gefühl verstummte sie statt dessen gänzlich, und plötzlich, als müßte sie sich anstatt des Wortes wenigstens durch die Gebärde helfen, glitt sie nieder vom Stuhl und kniete bei Erik hin, -- wie auf einen ihr nun zugewiesenen Platz, erwartungsvoll, mit einem Blick wie ein Kind um Weihnachten.

Sie fühlte sich so glücklich. Zu Hause. Geborgen. Von hier aus mußte alles Gute kommen.

Er strich ihr leise über das Haar. »Also höre unsern Vertrag zu Ende,« sagte er in dem ruhigen Tone, unter dem sie ganz still wurde und lauschte, »wenn du mir deine Geschichten schenkst, dann schenke ich dir auch etwas. Du sollst, soweit es an mir liegt, nicht in deiner eigenen Phantasie stecken bleiben, sondern mit klarem Blick so weit schweifen lernen, wie das Leben -- das wirkliche, herrliche Leben -- reicht. Und, wenn es auch anfangs Anstrengung von dir verlangen sollte, meinst du nicht, daß ich dich damit

etwas Schöneres lehren werde, als du bisher dir geträumt und zusammengedichtet hast?«

»Ach ja!« rief sie sehnsüchtig, als strebe sie verlangend beide Hände nach etwas Erwartetem aus, -- »das ist sie ja: von allen die allerschönste Märchengeschichte!«

Ihm fiel der Ausdruck auf, weil sie ihn schon im Schulhof den Mädchen gegenüber gebraucht hatte.

»Gerade das sagtest du ja, als du heute morgen den Mädchen erklärtest, daß du etwas Neues vorhabest. Was war es denn?«

Zu seinem Erstaunen fuhr Ruth zusammen, und senkte den Kopf.

Erik sah betroffen aus.

»Was war es?« fragte er streng.

»Ich kann es nicht sagen,« versicherte sie scheu, »bitte, bitte nicht.«

Er faßte ihre Hand hart im Gelenk, so daß es sie schmerzte.

»Wenn es etwas ist, was dir so schwer fällt, auszusprechen, dann ist es um so notwendiger, daß du es sagst. Ich muß es wissen, -- jetzt gleich, Ruth.«

Sie versuchte, die schmerzende Hand aus der seinen zu ziehen, und als es ihr nicht gelang, senkte sie das Gesicht noch tiefer, so daß es sich an seinem Rockärmel fast versteckte.

Er bog ihren Kopf zurück und sah ihr in das Gesicht. Es war über und über in Glut getaucht.

»Es hilft nichts, sich zu verstecken,« sagte er unerwartet sanft, »du wirst mir immer nachgeben müssen, mein Kind. Mach es kurz!«

Ihre Hände schlangen sich nervös auf seinen Knieen ineinander, dann hob sie sie mit einer bittenden Gebärde zu ihm auf.

»Es war nur, -- ich hatte alle diese Geschichten auf einmal so satt; alles stockte auf einmal, -- nichts mochte ich mir weiter ausdenken. So schön ich es mir auch ausdachte, mit so vielen Menschen drin ich es nur auch ausdachte, -- ich blieb immer allein. Die Menschen grüßten, und gingen vorüber. Und da -- da kam eine solche Sehnsucht, -- seit vier Tagen solche Sehnsucht. Ich konnte nicht mehr spielen. Nie mehr.«

»Sehnsucht -- wohin?« fragte er halblaut.

»Hierher!« sagte sie mit leiser Stimme und wandte den Kopf hinweg.

Er ließ ihn frei, ließ zu, daß sie ihn wieder an seinem Rockärmel versteckte.

Beide Arme hatte er um sie geschlungen.

II.

Erik saß bei Ruths Onkel und Tante im Empfangssalon, hielt Hut und Handschuhe auf den Knieen und blickte nachdenklich darauf nieder, während er dem Gespräch der beiden zuhörte.

»Ich finde, mit deiner Reise stimmt es gut zusammen, Mathilde,« sagte der Onkel jetzt, »denn während du mit Liuba in Wiesbaden bist, ist Ruth gerade so ganz unbeaufsichtigt hier. Ich weiß ohnedies nicht, was die Kleine mit den langen Ferien anfangen soll, da in diesem Jahr die meisten Bekannten nicht aufs Land, sondern ins Ausland gehen.«

Erik besaß ein scharfes Auge für die Außenseite von Menschen und wurde stark durch dieselbe beeinflußt. Der Onkel, mit seinem aschblonden, schon etwas graugemischten Haar und Bart, mit den schmächtigen Schultern seiner elegant gebauten Gestalt und mit seinen frauenhaft feinen Händen, gefiel ihm recht gut. In Ton und Haltung erinnerte er ein wenig an Ruth. Dagegen empfand Erik gegen die Tante eine ausgesprochene Antipathie.

»Solche Besuche bei allerlei Bekannten auf dem Lande wären jetzt auch durchaus keine geeignete Beschäftigung für Ruth,« bemerkte er aufblickend; »sie muß zu thun haben, -- wirkliche Arbeit und Anstrengung muß sie haben. Selbst körperliche oder geistige Ueberanstrengung wäre noch besser als Mangel an Beschäftigung. In diesen Jahren braucht man starke Nahrung, und

Ruth braucht sie am meisten.«

»Siehst du; was sage ich immer?« fiel die Tante ein, und nickte ihrem Mann bedeutsam zu; »ich sage immer: man läßt sie viel zu viel gewähren. Aber du hast das immer am bequemsten gefunden.«

»Lieber Gott! was wolltest du denn auch mit solchem kleinen Frauenzimmer anfangen,« versetzte der Onkel begütigend, »man konnte sie doch nicht etwa anstellen, Stuben zu scheuern?«

»Nein, weißt du, lieber Louis! das brauchst du mir wirklich nicht vorzuhalten, -- es ist ja gerade, als ob ich Ruth Dinge verrichten ließe, die sich nur für den niedersten Dienstboten schicken!« sagte seine Frau, die scherzende Uebertreibung unerbittlich ernst nehmend, »aber ein wenig sich im Häuslichen umsehen, -- das hätte Ruth ganz wohl können. Liuba wird ja auch dazu angehalten. Es ist doch nun einmal der Beruf der Frau.«

Erik betrachtete mit schlecht verhehltem Spott in den Augen die große, stattliche Erscheinung der Tante, an der es ihm charakteristisch für ihr ganzes Wesen vorkam, daß die ihr gewohnten guten Formen des äußeren Benehmens einen gewissen Mangel an natürlicher Grazie nicht verdecken konnten.

»Was das anbetrifft,« unterbrach er sie ungeduldig, »so brauchen Sie sich dieser Versäumnis wegen nicht weiter anzuklagen. In einem so von allen Seiten bedienten Hause bleibt die sogenannte ›häusliche Hilfe‹, bestehe sie nun im Blumenbegießen oder Kaffeekochen, im besten Fall eine gleichgültige Spielerei, -- im schlimmern Fall weckt sie die Einbildung, man habe etwas geleistet. Dagegen hätte ich gegen das Stubenscheuern nicht viel einzuwenden.«

Der Onkel lachte erfreut auf. »Jetzt haben Sie es aber mit meiner Frau gründlich verdorben!« drohte er scherzend, »aber ich muß bekennen, daß ich gar nicht begreife, warum sie alle beide so versessen darauf sind, Ruth ins Joch zu spannen. Natürlich habe ich nicht das Geringste gegen den Unterricht, den Sie vorhin als wünschenswert vorschlugen, -- im Gegenteil, es freut mich für die Kleine. Aber ich möchte Sie doch bitten, das mit dem Stubenscheuern auch nicht einmal symbolisch auszuführen. Nicht ins Geistige zu übertragen. Machen Sie es nur nicht zu ernsthaft. Ruth ist es so gewohnt, umherzulaufen und in ihrer Faulheit vergnügt zu sein.«

»Ich glaube, Sie täuschen sich,« entgegnete Erik in bestimmtem Ton, »Ruth ist weder faul noch vergnügt. Sie ist es gewohnt, sich in einem selbstgemachten Traumdasein vollständig zu erschöpfen. Sie ist dadurch zum Teil ihrem Alter vorausgeeilt, zum Teil aber auch hinter ihrem Alter zurückgeblieben. Ich habe noch nie eine so ungleiche Entwicklung gesehen. Wenn dieselbe nicht rechtzeitig aufgehalten wird, so läuft Ruth Gefahr, an ihrer Phantasie geistig zu erkranken.«

Der Onkel schüttelte verwundert den Kopf.

»Das ist doch kurios,« sagte er, »ich habe Ruth stets für ein höchst praktisches kleines Frauenzimmer gehalten. Von Phantasie war doch nie eine Spur an ihr zu bemerken. Alles was sie sagt, ist ja so direkt und nüchtern. Und am liebsten sagt sie gar nichts. Sie sollten nur wissen, wie nüchtern sie in allem ist, wo die jungen Mädchen sonst ihre Phantasie sitzen haben! Das hat mir stets so gut gefallen. Da kann Liuba gar nicht mitkommen.«

Seine Frau sah ihn verletzt an.

»Glücklicherweise nicht!« bestätigte sie etwas erregt, »Liuba würde nicht umhergehen, wie in einen grauen Sack gekleidet, bloß weil es so am bequemsten ist. Und überhaupt, -- denken Sie nur, neulich höre ich, wie meine Tochter zu Ruth sagt: ›paß nur auf; wenn du ein Jahr älter bist, dann wirst du schon wissen, was schön und häßlich ist, und wirst am Spiegel fragen: Wie gefall' ich ihm?‹ -- -- Mein Gott, Sie wissen ja, wie junge Mädchen so untereinander reden! Aber was antwortet Ruth darauf? Sie lacht nur, und dann fragt sie erstaunt: ›Warum nicht lieber: wie gefällt er mir?‹«

In diesem Augenblick ging die Thür auf, und Ruth trat ein.

Sie kam aus ihrem Zimmer, ohne eine Ahnung, daß sie Besuch vorfinden würde. Als sie so unerwartet Erik erblickte, fuhr sie zurück und wurde glühend rot. Diese plötzliche Anwesenheit seiner Person inmitten der Ihrigen, die ihr so fern standen, -- die unerwünschte Vermischung eines sie ganz erfüllenden Bildes mit der Umgebung, die sie mied und floh, machte einen ganz seltsamen Eindruck auf sie. Etwa so, wie wenn eine Traumgestalt aus herrlichen Phantasien ins wirkliche Leben niedersteigt, um ein banales Gespräch zu führen; -- etwa so, wie wenn man das Intimste, was nicht einmal Worte besitzt, in die Sprache des Pöbels übersetzt findet.

Daß Erik herkommen, daß er sich überhaupt mit ihren Verwandten auseinandersetzen mußte, das fiel ihr nicht im geringsten ein. Er hätte das schon so einrichten müssen, daß es eine Angelegenheit aus einer andern Welt -- aus ~ihrer~ Welt blieb. Lieber noch wäre sie dann des Nachts, heimlich, und auf bloßen Füßen bis zu ihm hingelaufen.

Entsetzlich rot und linkisch sah sie aus, wie sie sich da, verlegen und mit scheuem Gesicht, in die Thürspalte drückte. Aber nicht Verlegenheit empfand sie, sondern eine unentwirrbare Mischung von Zorn und Scham, -- Scham darüber, daß etwas Zartes, ihr Zugehöriges, vor fremden Augen herumgezeigt und besprochen wurde.

»Nun, Ruth, benimmt man sich so?« bemerkte die Tante verweisend, »kannst du nicht näher kommen?«

Da that sie etwas Wunderliches. Sie hob beide Hände vor die Augen, und so, mit scheuklappenartig verdecktem Gesicht, ging sie, wie ein Kind, das sich vor fremden Gästen fürchtet, durch das Zimmer bis vor den geschnitzten, runden Sofatisch, um den sie saßen.

Der Onkel lachte, seine Frau schüttelte mißbilligend den Kopf und sagte strafend: »Ein so großes Mädchen!«

Erik, der bei Ruths Eintreten den Kopf nach ihr gewandt hatte, blickte sie schweigend und aufmerksam an. Als sie dicht neben ihm stand, hob er die Hand und zog ihr die Hände vom Gesicht fort. »Warum willst du mich heute nicht ansehen, Ruth?« fragte er sie.

Sie antwortete nicht. Noch war sie sehr rot und hielt die Augen zu Boden gesenkt. Dieses »Du«, das er zu ihr sagte, und das sie gestern so dankbar hingerissen hatte, verletzte sie heute beinahe. Es klang ganz anders -- hier, an dieser Stelle, -- es klang wie die Anrede, die man einem Kinde gegenüber wählt, das unter lauter Erwachsenen dasteht. Ja, sie stand ihm und den andern ~gegenüber~, und sie verhandelten da über sie, als wäre sie verraten und verkauft, -- als handle es sich gar nicht um ihre -- ~ihre~ eigene, ~eigenste~ Angelegenheit.

Durch Erik fühlte sie sich verraten und verkauft.

»Sie lernen ja Ruth von einer liebenswürdigen Seite kennen,« meinte der Onkel, noch immer lächelnd, »aber sie ist nicht so schlimm, wie es aussieht. Was ist dir nur in die Krone gefahren, Kleine? Verlegen hab' ich dich noch nie gesehen.«

Erik, der sie unverwandt ansah, suchte jetzt die Aufmerksamkeit von ihr abzulenken.

»Wir wollen schon mit einander zurechtkommen,« sagte er mit warmer Stimme und wandte sich an den Onkel mit einer Frage wegen Tag und Stunde des geplanten Unterrichts.

Ruth stand teilnahmlos daneben, ohne die Wechselreden der andern zu beachten. Nur die Röte wich allmählich von ihrem Gesicht und machte einem Ausdruck verhaltener Traurigkeit und Enttäuschung Platz. Sie blickte nicht auf, sondern studierte eingehend das glänzende Muster des Parkettfußbodens.

Da, als Erik schon Miene machte, sich zu verabschieden, hörte sie ihren Onkel sagen: »Also, wenn es Ihnen wirklich kein zu großes Opfer ist, erwarten wir Sie jedesmal hier, am Nachmittag, nach Ihren Schulstunden!«

»Nein!« warf Ruth plötzlich laut dazwischen. Es war, als ob sie aufwachte. Erstaunt und blitzend gingen ihre Augen vom einen zum andern; »~hierher?~ das ist ja ein Irrtum. Ich werde hinauskommen.«

Alle sahen sie verwundert an, als sie das so kategorisch, ohne eine Spur von Befangenheit erklärte. Erik aber erhob sich rasch.

»Das ist am Ende wirklich das Bessere,« stimmte er ihr unwillkürlich bei, »und wenn Ruth den Weg nicht scheut und den Abend dann bei uns verbringen will, so wäre es in der That während dieser Sommertage vorzuziehen.«

Er sprach nicht mehr mit ganz der gleichen, überlegenen Sicherheit wie vorhin, sondern etwas hastig. Ein schwacher Reflex von dem, was Ruth so peinigend und störend an der Situation berührt hatte, schien jetzt auch auf ihn überzugehen, als ahne oder begriffe er plötzlich ihre zornige Scheu. Als er ihre Augen so vorwurfsvoll und mit einem unkindlichen, fast strengen Blick auf sich gerichtet sah, da kam es ihm selbst mit einemmal sonderbar vor, daß er sie anderswo um sich hatte haben wollen, als in seinem eigenen, stillen Zimmer, -- dort, wo sie zu ihm gekommen war. Beinahe hätte der Zufall es so gefügt. Aber sie ließ keinen Zufall zu. Klar und zwingend wie eine Vision stand vor ihren Augen, was sie sich ersehnt und erträumt hatte.

Während Erik mit ihrem Onkel das Zimmer verließ, und die Tante hinausging, blieb Ruth regungslos stehen, die Hände auf dem Rücken, den Kopf gebückt, wie immer, wenn etwas sie sehr beschäftigte. Im Flur hörte sie die Hausthür gehen, dann einen

raschen Schritt auf der steinernen Treppe. Darauf wurde es ganz still.

Sie sah das Zimmer wie durch einen Schleier, überschüttet von blendendem Sonnenlicht, das durch die hohen Blattgewächse und Palmengruppen in beiden Fensterecken hindurchschimmerte und an den vergoldeten Rahmen der Gemälde aufblitzte, die schon einen dünnen Tüllbezug gegen Staub und Licht erhalten hatten.

Ruth ging langsam auf den Stuhl zu, auf dem Erik vorhin gesessen hatte. Sie setzte sich hin, legte beide Arme auf den Tisch und den Kopf darauf.

Und dann fing sie an bitterlich zu weinen. --

Bei Tisch, zu Mittag, beobachtete der Onkel Ruth nachdenklich. Es hatte ihm so sehr imponiert, daß Erik alles zu ergründen schien, was in ihr vorging. Da saß sie nun so schweigsam. Freilich konnte man nicht wissen, woran sie dachte. Aber das konnte dieser Lehrer doch auch nicht. Er war doch kein Hellseher.

»Woran denkst du eigentlich den ganzen Tag?« fragte Onkel Louis plötzlich ärgerlich.

»Ich? An gar nichts!« versicherte sie mit einem verwunderten Blick.

»Aber an irgend etwas mußt du doch denken. Das thut ja jeder Mensch. Woran dachtest du zum Beispiel jetzt eben?«

»Jetzt eben dachte ich an Großpapa,« sagte Ruth.

Darüber freute sich ihr Onkel und sah sie freundlich an. Er hatte seinen Vater unendlich lieb gehabt.

»Du warst erst fünf Jahre, als deine Eltern starben, und du damals hierher kamst; erinnerst du dich denn seiner noch?«

Sie nickte, und vor ihrem Blick tauchte die erste ganz bewußte und deutliche Erinnerung aus ihrer Kindheit auf: eine Generalsuniform, ein schneeweißer, großer Schnurrbart, und darüber zwei gütige blaue Augen -- Kinderaugen eigentlich.

»Einmal hob er mich aus dem Bett -- er sah so schön aus, mit Bändern und Sternen, und blitzte über und über, -- und da kam seine brennende Cigarette an meinen bloßen Arm. Ich schrie sehr. Und da kamen ihm Thränen in die Augen -- aber wirkliche, große Thränen, so daß die Augen ganz voll davon standen. Und dann drückte er mich an sich und küßte mich, -- auf den Arm und den bloßen Hals und das Gesicht und den ganzen Körper. -- So war Großpapa. -- Jetzt würde ich mir gern den Arm abbrennen lassen, wenn er mich nur noch einmal so küssen wollte!« fügte sie wild hinzu.

Man sah, wie es in ihr gärte. Großpapas Zärtlichkeit hatte sie nie vergessen können.

»Hast du Bilder und Andenken von ihm?« fragte der Onkel und dachte darüber nach, was er ihr schenken könnte.

Sie schüttelte den Kopf.

»Keine Bilder. Nur ein Knallbonbon. Das brachte er mir einmal vom Kaiser mit. Von einem Galadiner. Ich glaubte so bestimmt, es müßten goldene Kleider drin sein. Aber Großpapa meinte, es wären nur Kleider von dünnem Seidenpapier mit einem kleinen Rand von Flittergold. Da habe ich das Bonbon lieber nicht knallen lassen. Ich habe es noch. -- Und so sind eigentlich noch immer goldene Kleider drin.«

Dem Onkel kam ein Lächeln. Erik imponierte ihm lange nicht mehr so sehr. Großpapas Küsse, Knallbonbons, goldene Kleider und Kleider aus Seidenpapier -- das waren doch sicherlich normale und harmlose Phantasien eines Kinderkopfes. --

Als Ruth am nächsten Nachmittag zu ihrer ersten Unterrichtsstunde fortging, zupfte Onkel Louis sie tröstend am Ohrläppchen und raunte ihr zu: »Du! wenn du ihm weglaufen solltest, so nehme ich dich in Schutz!« --

Aber als Ruth diesmal am Gartenzaun des Landhauses stand, kam ihr nicht, wie neulich, der Gedanke an Weglaufen. Sie zauderte auch nicht mehr so lange einzutreten, sondern stieß die Pforte auf und ging geradeaus -- nicht hinten die Terrasse hinauf und in das Haus, sondern weiter, in die Tiefe des Gartens, der sie das erste Mal so gelockt hatte.

Dort stand Jonas bei den Obstbaumgruppen, emsig beschäftigt, Raupen zwischen den kleinen Blättern herauszusuchen. Eigentlich waren noch gar keine Raupen da. Aber er konnte es nicht erwarten, sie abzulesen.

Als er Ruth herankommen sah, riß er den breitrandigen Strohhut vom Kopf und machte ein verlegenes Gesicht, denn der Sonnenwärme wegen hatte er die Jacke abgeworfen.

»Papa ist im Hause!« bemerkte er diensteifrig und bückte sich nach seiner Jacke, die auf dem Rasen lag.

»Ja! Er stand am Fenster,« bestätigte Ruth, und lehnte sich gegen den dicken Stamm einer alten Ulme.

Daraus wußte er nichts zu entgegnen, und so schwiegen sie beide einige Augenblicke.

»Wie wunderschön!« sagte Ruth dann, ganz in ihren Frühling versunken, und breitete beide Arme nach den mächtigen, leise schwankenden Aesten empor, die über ihr rauschten.

Jonas sah angestrengt in die Höhe, gewahrte aber nichts.

»Wo ist das schöne?« fragte er verwundert.

»Diese kleinen, drolligen Ulmenblätter! Die andern Bäume haben schon viel größere Blätter. Aber diese sitzen noch so zusammengedrückt in den Knospen -- und alle miteinander an den Zweigspitzen, -- als getrauten sie sich nicht. Oder als guckten sie frierend nach den braunen, klebrigen Hülsen, die sie schon heruntergeworfen haben. Sieht es nicht aus, als wären sie in lauter kleinen Sträußchen auf dem Baum verstreut? Es sieht aus, als wären sie ihm nur so angeflogen. Und als könnten sie wieder wegfliegen.«

»Sie fliegen aber nicht weg,« versicherte Jonas und wandte sich wieder seinen vermeintlichen Raupen zu.

»Nein. Nur diese hier thun es,« bemerkte Ruth und streckte ihre Hand gegen den Kirschbaum aus, von dem unter Jonas' unvorsichtiger Berührung die zarten Blütenblätter auf ihren Arm niederschwebten.

»Dies hier sind gute Kirschen. Hoffentlich von den roten, durchsichtigen,« meinte Jonas, »denn die esse ich am liebsten. Sonst haben wir fast nur Apfelbäume und gewöhnliche Holzbirnen.«

»Sie sehen ebenso schön aus,« entgegnete Ruth; »wenn man am Gitter steht, sieht es aus wie ein Märchen. Aber später werden sie so grün und natürlich wie die andern Bäume. Nur kleiner.«

»Das muß so sein,« erklärte Jonas gleichmütig, »sonst würde der Rasenplatz ja niemals rechten Schatten kriegen. Und der ist das Beste vom Sommer. Denn gerade hier, am Springbrunnen unter den Obstbäumen, liegt meine Mutter im Ruhestuhl. Und sie kann die viele Sonne nicht vertragen.«

Ruth sah ihn mit Interesse an. Es kam ihr als etwas Besonderes vor, daß er sich seiner kranken Mutter wegen über die Bäume und den Schatten freute und die grünen Blätter besser fand, als all die wunderschönen weißen Blüten. Die Schulmädchen, die sie kannte, besaßen zwar meistenteils auch Mütter, aber die pflegten gesund zu sein, und nie hatte sie gehört, daß sie sich derentwegen auf den Sommer freuten, sondern immer nur wegen der Ferien. Und dann waren es Mädchen. Dies hier aber war ein Junge.

Sie betrachtete Jonas genauer, und er gefiel ihr sehr gut. Und auch er sah jeden Augenblick zu ihr hinüber, und auch sie gefiel ihm über die Maßen.

»Ist sie sehr krank?« fragte sie nach einer Weile zaghaft.

»Nicht sehr. Sie kann nur nicht aufstehen, -- schon viele Jahre nicht;« belehrte er sie, »wenn sie das thun will, dann nimmt Papa sie in die Arme und trägt sie. Das kann er so prachtvoll. Manchmal hat sie auch Schmerzen, und weint. Und dann muß Papa immer bei ihr sein, und das hilft ihr.«

Ruth wandte unwillkürlich den Kopf dem Hause zu, wo die kranke Frau lag, und wo er war, der sie trug, und der ihr half, wenn sie Schmerzen hatte.

»Hinter diesem Fenster,« sagte Jonas und wies mit der Hand über die Terrasse nach dem Wohnzimmer; »da ist eben ihr Stuhl der Sonne wegen hineingetragen worden.«

Aber im breiten Rahmen des geöffneten Fensters war nur Eriks Gestalt zu sehen, der ihnen den Rücken zukehrte. Und nun wandte er sich langsam um.

Ruth löste sich ein wenig hastig vom Stamm, an dem sie lehnte. »Jetzt will ich hineingehen,« sagte sie.

Nachdem Erik von der Straßenseite her Ruth in den Garten hatte treten sehen, war er wirklich an das Fenster des Wohnzimmers gegangen und hatte von Zeit zu Zeit nach der Obstbaumgruppe hinübergeblickt, wo sie mit Jonas stand und plauderte.

Klare-Bel lag neben dem Fenster, mit einer mühsamen und kunstvollen Handarbeit beschäftigt, die darin bestand, an einer schadhaft gewordenen Damastserviette das Muster nachzuziehen. Man nannte diese Arbeit in Holland »Maazen«. Und wer es ernst damit nahm, der wollte das »Maazen« bis auf das Ausbessern der Strümpfe und Unterjacken erstreckt wissen.

»Kommt Ruth noch immer nicht herein?« fragte sie nach einer langen Pause.

Er zog die Uhr.

»Nein. Noch fehlen einige Minuten an der Zeit,« bemerkte er einsilbig.

»Das ist doch eigentlich kein Grund, nicht hereinzukommen, wenn sie einmal da ist. Aber vielleicht steht sie viel lieber im Garten und plaudert mit Jonas, als daß sie im Zimmer sitzt und lernt, Erik. Das ist am Ende auch ganz natürlich.«

Er schwieg und blickte mit einem Ausdruck von Ungeduld auf ihre Handarbeit nieder. Erik konnte das »Maazen« nicht leiden. Er behauptete, es verdürbe die Augen, und sogar den Charakter.

»Bitte, hör' jetzt einen Augenblick mit dem Sticheln auf,« sagte er und nahm ihr einfach die Nadel aus der Hand, »ich weiß nicht, -- das Zeug macht nervös.«

Dann sah er aber doch wieder auf die Uhr.

Ihm war die Ahnung gekommen, daß es doch nicht so ganz von selbst gelingen werde, bestimmende Macht über Ruth zu gewinnen, wie er es sich an jenem wundersamen Maiabend gedacht. Sie wollte durch keine unerwartete oder unerwünschte Bewegung seinerseits in ihrem selbständigen Traumleben gestört werden, und erhob sie ihn auch zum Helden ihrer »allerschönsten Märchengeschichte«, so mußte er sich dabei doch ganz still verhalten und auf alle ihre Intentionen eingehen, -- sonst entglitt sie ihm leise wieder, so leise und traumhaft, wie sie in sein Leben gekommen war.

Das durfte nicht sein; der Erzieher in ihm litt es nicht, daß ihm mißlinge, was er sich mit Ruth vorgenommen hatte. Er wußte: er würde nicht eher ruhen, als bis er ihren Willen ganz in der Hand hielte. Aber welch eine zarte Hand wollte er dann für sie haben!

Neben diesen pädagogischen Erwägungen erfüllte ihn eine ungeduldige Freude. Freude über den Kampf, der ihm mit Ruth bevorstand. Erik, der andre weit besser zu erforschen verstand, als sich selbst, ahnte gar nicht, wie stark sich unter dem Deckmantel des Pädagogen ein jugendliches, herrschsüchtiges Verlangen in ihm regte.

Er wandte sich dem Garten zu.

»Jetzt kommt sie!« sagte er, und wirklich, es klang wie ein Seufzer der Erleichterung.

Seine Frau unterdrückte ein Lächeln und nahm ihre Arbeit wieder auf. »Nun, viel Erfolg, Erik! Vergiß nur nicht, daß wir um neun Uhr den Thee nehmen. Du wirst sie hungrig und durstig machen, denke ich mir.«

Er war über den Flur in seine Arbeitsstube gegangen und öffnete schon von innen her die Thür, als Ruth kam und anklopfen wollte.

»Endlich!« bemerkte er, während sie eintrat, »weißt du, Ruth, was meine Frau soeben meinte? Sie meinte, du seiest gewiß viel lieber mit Jonas draußen im Garten, als bei mir hier in der Stube. Was sagst du dazu?«

Sie blickte ihn unsicher an und setzte sich auf seinen Wink in den Ledersessel, der am Fenster stand. Dann erwiderte sie mit niedergeschlagenen Augen: »Ich bin doch gekommen, weil ich wollte, -- nur weil ich's wollte. Daß Jonas auch hier ist, wußte ich doch gar nicht. Das ist ja nur Zufall. Den fand ich hier.«

Er wußte nicht gleich, was ihn an der Antwort, die keine war, überraschte. Sie betonte ausschließlich, daß sie ganz aus freien Stücken hier sei. Auf einen Vergleich ließ sie sich vorsichtshalber gar nicht ein.

»Wenn es in der Folge nur nicht umgekehrt kommt, mein liebes Kind,« sagte er, an seinen Schreibtisch tretend, und legte einige Hefte und Bücher zurecht, »denn mit Jonas plaudern oder im Garten umhergehen wirst du ja in der Folge nur, wenn du ›willst‹, das

heißt, wenn Stimmung und Laune dir zufällig danach stehen. Hier hingegen, wo du freiwillig hergekommen bist, kann es doch nicht ganz so bleiben. Hier wird dich notwendigerweise etwas fest Bestimmtes erwarten, das vom Augenblick und seinen Stimmungen unabhängig ist. Also auch etwas, wovon du manchmal denken wirst: ›ganz so möchte ich's nicht, -- ganz so meinte ich's nicht, -- dies da soll anders sein, -- das da soll heute nicht da sein‹. Ist es nicht so?«

Sie schwieg hartnäckig und machte ein verschlossenes Gesicht. Es war ihr wirklich ungefähr das durch den Kopf gegangen, was er da sagte. Aber daß er das wissen konnte, kam ihr sehr unangenehm vor.

Er blieb bei ihr stehen und nahm ihr die Wollmütze, die sie aufbehalten hatte, vom Haar.

»Nun, Ruth, gestern hast du mich nicht ansehen wollen, und heute willst du mich nicht anreden. Hältst du so unsern Vertrag? Und ich hoffte bestimmt, daß du mir viel erzählen würdest. Viel -- alles. Alle deine schönsten Geschichten.«

»Nein,« erklärte Ruth, »nie und nimmer. Ich will nichts erzählen. Ich will alles für mich allein behalten.«

»Du Geizhals!« sagte er und lachte, »das ist sehr schlimm. Ist es nicht schlimm, wenn man einen zu Gaste geladen hat und dann die Hausthüre vor ihm zuschlägt? Aber zum Glück kannst du das gar nicht mehr, Ruth. Hast du mir nicht deine Geschichten geschenkt? Hast du das vergessen? Nun sind sie mein Eigentum. Ich kann mit ihnen machen, was ich will. Ich kann sie dir aus dem Kopf herausnehmen und für mich ganz allein behalten.«

»Ach nein!« fiel sie etwas lebhafter ein und griff unwillkürlich nach ihrem Kopf, »das geht ja gar nicht. Es geht nicht, wenn ich nicht will.«

»Du spricht so viel von deinem Willen, Ruth. Und daß du nur hier bist, weil du gerade willst. Aber weißt du denn eigentlich auch, ~wozu~ du es willst?«

Sie stutzte und blickte auf. Als sie nicht gleich eine Antwort fand, fügte er hinzu: »Ich weiß es für dich: du wolltest eben diesen Willen klären und erziehen lassen von jemand, der dich lieb genug dazu hat. Alles Lernen ist nur ein Mittel dazu.«

Ruth legte ihre Hände an die Seitenlehnen des Sessels, und ihr Gesicht wurde noch ablehnender. »Wie wenn sie ein Visier vorgelegt hätte!« dachte Erik, sie betrachtend. Aber hinter diesem Visier arbeitete eine steigende Erregung in ihr. Die passive Stimmung, in der sie heute hergekommen war, hielt unter Eriks Andrängen nicht stand, aber noch weniger vermochte sie den Traum und das seltsame Glück des ersten Abends wieder zu erhaschen. Sie verschloß und verbarg sich daher instinktiv vor ihm, wie vor einer Macht, die man sich erst genau ansehen muß, ehe man sich mit ihr einläßt.

»Alles ist heute anders!« murmelte sie.

»Es wird immer anders sein, als du es dir willkürlich ausmalst,« entgegnete er in ruhigem Ton, »und das soll es auch, Ruth! Es soll zu ernst sein für ein bloßes Spiel der Phantasie. Siehst du, auch ich habe mir etwas Schönes ersonnen und geträumt, das ich in dir verwirklicht sehen möchte. Ich versprach dir doch: für die Geschichten, die du mir ~erzählen~ wolltest, solltest du eine durch mich ~erleben~. Die Allerschönste -- sagtest du nicht so? Mit dem Erzählen mußt du es nun halten, wie du willst, aber mit dem Erleben wirst du es halten, wie ich will. Es war mein Geschenk für dich. Und wenn du heute auch nichts davon wissen willst, so wirst du es doch trotzdem annehmen müssen.«

Ruth wurde unruhig. Sie kannte nur zwei Sorten Menschen, und daß sie Erik in keiner von beiden unterbringen konnte, ängstigte sie. Die eine Sorte bestand aus ihrer jeweiligen täglichen Umgebung, die ihr meistens störend oder gleichgültig war und wirkungslos an ihr abglitt; die andre bestand aus den fremden Menschen, die sie, wie Schattenbilder, aus der Ferne betrachtete, und denen sie die äußere Anregung zu ihren Phantastereien entnahm. Zu denen konnte Erik nicht gehören, denn die thaten nur, was sie wollte, -- sie ~waren~ ja nur, was sie wollte. Er hingegen war eine Wirklichkeit, die auf sie eindrang. Sie konnte ihn aber auch nicht abwehren, wie sie die Ihrigen von sich abwehrte, denn es war etwas da, was sie mächtiger reizte und anregte, als es alle Schattenbilder zusammen gethan.

Sie sah ihn scheu an.

»Ich will lieber ein andres Mal kommen,« bat sie leise, »ich kann heute nicht lernen. Ich kann's nicht.«

»Doch! doch!« entgegnete er beschwichtigend, »du kannst es. Und im Grunde willst du es auch. Aber wir können nicht in jedem Augenblick den Kampf darum von neuem aufnehmen. Der muß ein für allemal entschieden werden. Du oder ich, Ruth! Einer von

uns beiden muß gehorchen.«

Da sprang Ruth plötzlich auf und sagte undeutlich: »Dann kann ich auch fortbleiben.«

Es war ihr ganz spontan, wider alle Ueberlegung, entfahren. Aber nun half es nichts. Nun war es heraus.

Erik sah, wie sie ganz blaß und über sich selbst erschrocken dastand, und ein heftiges Mitleid mit ihr erfaßte ihn. Ihm kam es vor, als habe er sie mißhandelt, und sein Blick wurde sehr weich.

Aber er dachte nicht daran, dieser weichen Regung nachzugeben. Er wünschte, die entscheidende Situation so scharf als möglich zum Austrag zu bringen. Am Gelingen zweifelte er nicht. Und voll Freude fühlte er: war es erst überstanden, so konnte er alle Strenge in die Rumpelkammer werfen. Dann war er Ruths für alle -- alle Zeit sicher.

»Gewiß kannst du fortbleiben,« bestätigte er ruhig, »wenn es sich für dich wirklich nicht um mehr gehandelt hat, als um einen solchen Zeitvertreib, wie ihr ihn unter euch im Schulhof treibt. Weißt du noch, was du von dem Fremden sagtest, den ihr in euer kindisches Spiel hereingezogen habt? ›Wenn er mir nicht gepaßt hätte, wenn er aus der Rolle gefallen wäre, die ich ihm zugewiesen, dann hätte ich mir einfach einen andern suchen müssen, -- ich hätte die Augen zugemacht und wäre fortgelaufen.‹ Ist es hiermit ebenso oder auch nur annähernd so, -- -- dann laufe nur fort.«

Während er sprach, fühlte er beständig das große Mitleid. Sie sah nur ein einziges Mal auf, und wie sie seinem weichen Blick begegnete, da war es, als ginge ihre passive Abwehr in eine Art von Angriff über, -- als suche sie nach einer Waffe, nach irgend etwas, was sie von ihrem Leiden befreien, ihm weh thun und ihr Macht geben könne. Ihm fielen die Worte ein, die sie vom Fremden gebraucht hatte: »Ich brauchte ihn eben, und da nahm ich ihn mir!«

Ruth langte nach ihrer Wollmütze, die auf dem Schreibtisch lag, und drückte sie zwecklos in den Händen zusammen.

»Ich will nach Hause gehen!« wiederholte sie, und zitterte am ganzen Leibe.

»Wie du willst.«

»Also adieu,« sagte sie, und ging langsam, wie gelähmt, der Thüre zu.

»Adieu, mein Kind.«

Sie hatte Mühe, den Thürgriff zu finden und niederzudrücken, ihre Hände waren kalt und gehorchten ihr nicht. Als aber die Thür offen stand, und sie in den Flur hinaustrat, da blickte sie beim Schließen der Thür mit brennenden Augen ins Zimmer zurück.

Erik saß auf dem von ihr verlassenen Ledersessel am Fenster. Er hatte den rechten Arm auf die Lehne desselben gestützt und die Hand über die Augen gelegt.

Und plötzlich überfiel Ruth das Bewußtsein: daß all sein Herrschenwollen im Grunde doch nur ein Dienenwollen sei. Plötzlich überfiel es sie: daß er eben jetzt leide, -- um sie leide, die ihn verletzt hatte.

Es traf sie mit einem Schmerzgefühl, aber dieses Gefühl war seltsam und berauschend; es lag Triumph darin. Es war ein Schmerz, der sich wie ein Glück anfühlte.

Noch immer zitterte sie am ganzen Körper, aber nicht mehr in der Angst der Flucht. Sie hatte mitten in der Angst ihrer Flucht Halt gemacht, sich gegen den Feind gekehrt und ihn besiegt gesehen.

Wer Ruth über den Flur gehen sah, der konnte meinen, sie sei trunken. --

Um neun Uhr -- Gonne hatte bereits den Thee und die gerösteten Brotschnittchen auf den Tisch gebracht -- kam Erik endlich in das Wohnzimmer herüber.

»Es ist doch nichts vorgefallen?« fragte seine Frau mit einem Blick in sein Gesicht, »Ruth ist ja schon so bald fortgegangen. Und ich dachte doch, daß sie mit uns bleiben sollte?«

»Für heute war es besser so,« versetzte er, und Klare-Bel fragte nicht weiter.

Aber Jonas that es statt ihrer.

»Ruth habe ich ganz ungeheuer gern,« versicherte er, »kommt sie bald wieder her, Papa?«

»Bald!« sagte dieser.

»Denke dir nur, sie wollte es mir nicht sagen,« plauderte Jonas weiter, »ich habe sie nämlich noch im Garten gesprochen, wie sie fortging. Da sah sie so kurios aus, Papa, ihre Augen waren so groß und glänzten so, -- sie sah aus, als ob sie gerade was geschenkt bekommen hätte.«

»Was geschenkt?« wiederholte Erik, und setzte das Theeglas, das er zum Munde führen wollte, hart auf das Tischtuch nieder.

»Ja, ganz gewiß, gerade so sah sie aus. Aber sie antwortete mir nicht, und dann, am Gitter, da bat sie mich um ein Glas Wasser.«

»Es ist ihr doch nicht unwohl geworden?« fragte Klare-Bel besorgt.

»Nein, aber sie zitterte ordentlich. Das Wasser habe ich ihr vom Brunnen geholt. Und dann ist sie fortgegangen. -- Ich habe ihr aber noch lange nachgesehen,« fügte Jonas hinzu.

»Gewiß warst du zu streng mit ihr, Erik,« sagte Klare-Bel, »ich konnte es dir schon ansehen, wie du hinübergingst.«

»Zu streng? Aber, Bel, dann sieht man doch nicht aus, als ob man etwas geschenkt bekommen hätte.«

Er sprach in leichtem Ton, doch beschämte ihn, was Jonas erzählt hatte. Es war etwas Neues, Unerwartetes, worin er sich nicht gleich zurechtfinden konnte. Daß sie trotzte und selbst, daß sie weglief, begriff er ganz gut und rechnete damit. Aber dies hier begriff er nicht. War es denn möglich, daß sie gern, -- mit Freude, fortging? -- -- Und daß sie nicht wiederkam? -- --

Während sie noch beim Thee saßen, zog draußen ein schweres Gewitter heraus. Klare-Bel blickte ängstlich nach dem Fenster, durch das man die dunkle, schwarzgelbe Wolkenbank am Himmel stehen sah. Ein Sturmwind fuhr durch die Baumkronen, schüttelte und beugte sie; der Tagesschein, den die lange Maihelle noch über den Garten gebreitet hatte, verschwand unvermittelt. Und gleich darauf prasselte, unter grellzuckenden Blitzen und gewaltigen Donnerschlägen, ein heftiger Platzregen nieder.

»Bitte, laßt doch die Fenster schließen! bitte, Jonas, iß nicht mehr! Ach, Erik, der Donner!« sagte Klare-Bel, die vor jedem Blitz die Augen schloß.

Erik stand auf, blieb einen Augenblick am Fenster stehen und schaute in den Aufruhr hinaus, dann schloß er es und kehrte zu seiner Frau zurück. Die Gewitterangst war etwas, das sie überkommen hatte, seitdem sie hilflos dalag. Als junge Frau kannte sie dergleichen nicht, und Erik würde es an ihr auch wohl nicht geduldet haben. Jetzt hatte er Geduld damit.

»Wenn man eine Lampe anzünden könnte! Es ist so dunkel geworden auf einmal. Und dann ist der Blitz so furchtbar hell, Erik!«

»Gonne braucht keine Lampe hereinzubringen,« erwiderte er lächelnd und legte seine Hand über ihre Augen; »bist du nun nicht geborgen, Bel?«

Sie nickte dankbar und drückte ihr Gesicht gegen seine Hände.

Es war ein arges Gewitter. Unaufhörlich folgten sich Blitz und Schlag. Auf Augenblicke sah der Garten aus wie unter bengalischer Beleuchtung, und im bläulichen Scheine konnte man die vom Sturm losgerissenen Blätter und Blüten in tollem Wirbel durcheinander fliegen sehen.

Wenn der Donner besonders gellend krachte, fuhr Klare-Bel jedesmal zusammen.

»Ob Ruth wohl schon zu Hause war, ehe es losging?« fragte sie.

»Längst. Sie muß zu Hause gewesen sein, ehe wir uns zu Tisch setzten,« beruhigte er sie, »und der Diener wird sich freuen, daß er sie bei diesem Unwetter nicht zu holen braucht.«

Es währte noch eine ganze Weile, ehe Blitz und Sturm auch nur ein wenig nachließen, und der grobkörnige Regen mit schwächerem Ton auf das Dach niedertrommelte.

»Nun, Bel, jetzt wird es besser,« sagte Erik und nahm seine Hand von ihrem Gesicht. Er öffnete wieder das Fenster, durch das die abgekühlte Abendluft jetzt frisch und gewürzig hereinströmte.

Jonas stand vor dem Fenster auf der regenumsprühten Terrasse und blickte, über deren Brüstung gebeugt, in den verwüsteten Garten hinaus. Ein großer Ulmenast war quer über den Kiesweg gestürzt, die Obstblüte hatte den Aufruhr in der Natur mit dem Leben bezahlen müssen.

»Nun sind sie wahrhaftig davongeflogen, alle mit einemmal, die weißen Blüten,« rief Jonas bedauernd, »so wie Ruth es gesagt hat! wie leid wird es ihr thun. Sie fand sie so schön. Aber dort oben wird es schon wieder blau, Papa.«

»Gott sei Dank!« meinte Klare-Bel, »solche Aufregung und Verwirrung draußen ist schrecklich. Man wird förmlich mit hingerissen.«

»Ja, das ist nichts mehr für dich, meine Arme,« sagte Erik, »es gab aber Zeiten, wo du solche Gewitterstürme und dazu das Brüllen des Meeren aushalten mußtest, ohne daß ich bei dir war.«

»Das war auch entsetzlich, Erik, ganz entsetzlich war es,« versicherte sie zusammenschaudernd, »damals, als du mit den Leuten hinausfuhrst, wenn ein Schiff in Gefahr war. Und das eine Mal, weißt du, wo du ganz allein es warst, der den Niels und die andern dazu beredete. Denn die hatten ja auch Frau und Kind. Aber das hast du immer so gut gekonnt: die Leute bereden. ›Es wird gehen!‹ sagtest du ihnen, und da glaubten sie dir.«

»Du glaubtest mir ja auch, Bel, wenn du allein Zurückbleiben mußtest, und wenn es dir schien, als ginge das nicht.«

»Ja, Erik. Manchmal dachte ich, der Schreck würde mich töten. Aber dann sagtest du so zuversichtlich: ›Wenn ich nach Hause komme, naß und müde, Bel, dann muß ich da doch meine Frau finden und den kleinen Jungen, und beide vergnügt und gesund.‹ Nun, und da mußte es wohl so sein.«

Er schwieg. Vor seinem Blick stand eine Sturmnacht, in welcher er, aus wirklicher Lebensgefahr heimkehrend, seine Frau gefunden hatte, wie sie, das Kind neben sich, mitten in der kleinen Stube auf den Knieen lag und laut betete.

Einen Augenblick lang war er fast bestürzt auf der Schwelle stehen geblieben, denn noch nie hatte er sie beten sehen. Als sie heirateten, waren ihm unter ihren Sachen ein paar Andachtsbücher in die Hände gefallen, und wie sie ihn darin blättern sah, fragte sie ihn: »Glaubst du an das, was darin steht?« Er hatte mit ernsten Augen aufgeblickt und geantwortet: »Nein, Bel.« Seitdem war dieser Gegenstand nur noch ein einziges Mal, nach Jahren, im Gespräche wieder berührt worden, und da war es ihm mit innerem Staunen aufgegangen, daß seine Frau, ohne es auch nur selbst recht zu merken, ihren Glauben gar nicht mehr besaß. Auf seine Frage, wie denn das geschehen sei, hatte sie mit ihrem freundlichen Gleichmut verwundert erwidert: »Ja, Erik, wenn es doch gar nicht so ~ist~, -- was kann es dann noch nützen, daran zu glauben?«

Und als er nun in jener Sturmnacht in seinen hohen Schifferstiefeln und seinem nassen Wollwams hereintrat, da hörte sie auf zu beten und streckte ihm mit einem Freudenschrei beide Arme entgegen. Er hob sie von den Knieen auf und küßte sie. »Thust du ~das~, Bel, wenn ich nicht bei dir bin?« fragte er sie leise.

»Wenn du nicht bei mir bist, Erik!« sagte sie weinend, »denn dann, scheint mir immer, muß ich es thun!«

Damals trug sie sich mit dem zweiten Kinde. Kurz darauf that sie den gefährlichen Sturz, der ihr die Gesundheit kostete, und das Kindchen wurde tot geboren.

Als Gonne mit einer brennenden Lampe hereinkam, fuhr Erik aus seinen Gedanken auf.

»Ich möchte jetzt zu mir hinübergehen,« bemerkte er und küßte seine Frau auf die Stirn, »ich habe noch Schularbeiten für morgen. Sobald du müde wirst, mußt du mich rufen lassen.«

Bei Erik im Zimmer war es schon fast dunkel. Nur von ein paar rosenroten Wölkchen, die sich von der großen Wolkenmasse losgewunden hatten und nun mit heiterm Leuchten selbständig auf einem breiten Stück Himmelsblau herumschwammen, fiel ein schwacher Schein durch die Fenster. Man konnte in ihm den Schreibtisch, den Bücherschrank, das alte lederbezogene Sofa an der Längswand ziemlich deutlich erkennen.

Erik stutzte und blieb auf der Schwelle stehen.

Er hatte einen Augenblick klar zu sehen geglaubt, daß auf dem Ledersessel am Fenster Ruth säße. An Halluzinationen konnte er doch nicht leiden.

Mit einem Gefühl des Aergers über sich selbst schloß er hinter sich die Thür und ergriff von einem Nebentisch einen Leuchter, um Licht zu machen.

Da fuhr er zusammen und setzte den Leuchter wieder hin. Auf dem Sessel saß wirklich jemand.

»Ich bin es!« sagte eine klägliche Stimme.

»Ruth!« rief er laut.

Sie war es. Durchnäßt bis auf die Haut, in Kleidern, von denen das Wasser schwer auf den Fußboden herabtropfte, und die an einer Seite zerrissen niederhingen. Ihre Zähne schlugen hörbar aneinander.

Erik hatte sie in seine Arme gerissen und betastete sie besorgt und erregt, mit liebkosenden Händen, -- Brust und Arme und das verworrene Haar, das so eng und feucht um ihr kaltes Gesichtchen klebte.

»Wann -- wann, -- von wo bist du gekommen? Warst du denn nicht zu Hause?«

»Ich war nicht zu Hause,« sagte sie zaghaft und schmiegte sich frostbebend an ihn; »ich bin vom Stadtbahnhof wieder zurückgefahren. Und hergelaufen. Gerade als es losging. Ich will nicht nach Hause,« fügte sie flehend hinzu, »mich friert so!«

»Mein Liebling, du sollst nicht nach Hause! Du sollst hier bleiben! Aber wie lange mußt du hier schon sitzen? Wie konntest du das nur thun? Und es hat dich doch niemand an der Thür auf der Terrasse läuten hören?«

»Ich habe nicht geläutet. Ich schämte mich. Ich bin hier in das Fenster geklettert. Aber es ging schwer,« gestand sie, und Mund und Augen lachten übermütig zu ihm auf.

»Und dann? Wenn ich nun gar nicht mehr hier hereingetreten wäre?«

»Dann hätte ich die ganze Nacht hier sitzen müssen!« erklärte sie schaudernd und rieb den Kopf an seinem Arm wie eine naß gewordene Katze. Und dann sagte sie ganz leise: »Denn vor den andern konnte ich es nicht sagen. Und doch mußte ich es sagen. Deshalb kam ich ja zurück! Ich mußte sagen: Ich will alles thun, was ich soll.«

Eine Viertelstunde später war Jonas nach dem Bahnhof geschickt worden, um ein Telegramm an Ruths Onkel aufzugeben, daß sie draußen übernachten müsse. Ruth selbst wurde wohlverpackt in Jonas' Bett gelegt, welches Gonne eilig für sie hergerichtet hatte. Dann bekam sie heißen Thee zu trinken und fiel in einen unruhigen Schlummer.

Jonas fühlte sich sehr stolz, als er bei seiner Rückkehr hörte, daß er Ruth das wichtigste Möbel, das der Mensch besitzt, sein Bett, abgetreten habe. Und voll Begeisterung streckte er sich an diesem Abend in Eriks Arbeitsstube auf dem alten Lederdiwan aus, dessen Polsterwerk an Härte und unbegreiflichen Beulen nichts zu wünschen übrig ließ. Auch war Jonas zu aufgeregt, um bald einzuschlafen, und alle Augenblicke guckte er durch die Thürritze und fragte, was denn Ruth jetzt wohl mache.

Sie fieberte heftig und sprach im Halbtraum wild und wirr durcheinander.

»Der Sandkuchen,« hörte Erik sie mehrmals ängstlich sagen, »er drückt mich so. Er ist immer größer und größer geworden. Ich fürchte mich. Er verschlingt mich. Und anfangs war er so weich und klein und so wunderschön zum Kneten!«

Erik wachte bei ihr, bis der Morgen aufstieg.

Sie warf sich ruhelos in den Kissen umher, und immer wieder sprach sie mit sich selbst in abgerissenen Sätzen. Aber wie ihm schien, waren es keine eigentlichen Fieber-Phantasien, sondern sie enthielten einen deutlichen Zusammenhang. Es kam ihm der Gedanke, daß sie vielleicht oft so mit sich selbst spräche, ohne daß ein Mensch es hörte, und daß jetzt das Fieber vielleicht nur den gewaltsamen Anstoß gegeben habe, es unbewußt vor Menschenohren zu thun.

Er konnte ihren Worten entnehmen, daß sie sich fortwährend noch mit dem Gewittergang beschäftigte. Manchmal erwähnte sie diesen in einer Weise, als habe sie ihn gar nicht selbst gemacht, sondern als sei sie gegen ihren Willen des Weges geschoben worden, -- mit Gewalt hinausgetrieben in Sturm und Blitz und Donnerschläge. Sie sah sich auf dem einsamen, dunkeln Weg dahingehen, während Hagel und Wind ihr entgegentosten, und ihre Füße im tiefen, durchweichten Lehmboden stecken blieben.

Und damit vermischte sich dann ein andres Fieberbild: der Versuch vor etwas fortzulaufen, ohne es zu können, wie es wohl im Traume geschieht.

»Ich laufe und laufe, und bleibe immer am Fleck!« klagte sie unruhig, und das Fieber nahm zu, wenn sie daran dachte.

Am nächsten Morgen war Ruth fieberfrei. Als Erik, zu seinem Schulgang fertig angekleidet, zu ihr hereintrat, saß sie aufrecht im Bett, in einem Nachtjäckchen von Klare-Bel, das ihr zu kurz und zu weit war, und blickte ihm mit schüchternen Augen entgegen.

Auf der Bettdecke lagen Blumen verstreut, die Jonas in aller Frühe hereingeschickt hatte. Sogar ein paar fast unversehrte Zweige von seinem Kirschbaum waren dabei. Er hatte sie mit Todesverachtung abgerissen.

»Muß ich nun nach Hause?« fragte Ruth ängstlich.

»Nein, mein Liebling. Du sollst hier doch nicht nur krank liegen, sondern auch gesund umherspringen. Meine Stube wartet ja noch auf dich. Wollten wir nicht zusammen arbeiten?«

»Ja!« sagte sie eifrig und machte eine Anstrengung, wie um aufzustehen, so daß die Blumen von der Decke glitten.

»Aber, mein liebes Kind, doch nicht jetzt im Augenblick. Später!«

»Später!« wiederholte sie gehorsam, indem sie sich zurücklehnte und die Augen schloß.

Erik faßte nach ihrem Handgelenk und prüfte den Puls.

»Wenn ich heute von der Stadt nach Hause komme,« bemerkte er dazwischen, »dann finde ich dich im Garten, im Sonnenschein, und ganz gesund. Nicht wahr?«

»Ja,« sagte sie folgsam, ohne die Augen zu öffnen. Aber auf ihrem Gesicht war ein Ausdruck von Leiden oder Kummer, der ihn beunruhigte.

Er beugte sich zu ihr nieder und strich sanft das Haar aus ihrer Stirn.

»Aber nicht nur gesund, Ruth,« fügte er hinzu, »sondern auch froh! Nicht diesen in sich gekehrten, verschlossenen Ausdruck! Du darfst dich nicht wieder so scheu vor mir zuschließen, mein Kind. Bist du denn nicht mehr gern bei mir? Thut es dir nicht wohl, hierher zu gehören?«

Sie schlug die Augen auf und blickte ihn voll an.

»Es ist, als ob ich ins Meer gestürzt wäre,« sagte sie. --

Erik ging früher als sonst fort, um noch vor Beginn seiner Schulstunden bei Ruths Verwandten vorsprechen zu können. Er traf sie beim ersten Frühstück. Basil ließ ihn erst auf seinen ausdrücklichen Wunsch, etwas zaudernd, in den Speisesaal eintreten, wo die Tante, im Morgenhäubchen, sich noch hinter dem Samowar befand. Sie zeigte sich ein wenig befremdet über den allzu frühen Besuch. Der Onkel, schon im Begriff, wie allmorgendlich, ins Ministerium hinunterzugehen, saß in Militärbeinkleidern und eleganter geschlossener Joppe beim letzten Glase Thee. Er sprang auf und kam Erik mit lebhaften besorgten Fragen nach Ruth entgegen. Erik erzählte, wie sie auf dem Heimweg umgekehrt, ins Gewitter geraten und vor Aufregung krank geworden sei.

»Das kleine Ding!« äußerte der Onkel in zärtlich besorgtem Ton; er warf sich im stillen vor, daß er Ruth eigentlich dazu aufgemuntert habe, »wegzulaufen«. »Wie schlimm muß das für sie gewesen sein! Schon wenn Ruth einmal unerwartet vom Warmen ins Kalte gerät, da schaudert ihr die ganze Haut und sie zittert. Und dann kann sie sich auch so ganz entsetzlich fürchten.«

Liuba kam herein, begrüßte Erik und schenkte sich mit schlafgeröteten Augen Thee ein; sie war in Gesellschaft gewesen und spät aufgeblieben.

»Ja, Courage hat Ruth mal nicht,« bestätigte sie, »als wir ihr einmal eine Raupe auf den Hals setzten, fiel sie in Krämpfe.«

Erik blickte mit bestürztem Gesicht auf.

»Hat sie ~dazu~ Anlage gezeigt?« fragte er langsam.

»Aber nein, sonst niemals!« erwiderte der Onkel ärgerlich, »es ist schon Jahre her. Dreizehn Jahre war sie wohl alt. Es war irgendwo in der Schweiz. Ruth trug ein dünnes Sommerkleid mit bloßem Halse. Es war sehr schlecht von euch, sie so zu erschrecken, Liuba. Du solltest lieber davon still sein.«

»Wir haben uns doch nichts Böses dabei gedacht,« sagte Liuba, »warum saß sie auch immer so ganz versonnen und vertieft herum, so ganz wie ein Stein, der weder sieht noch hört. Es störte das Spiel der andern. Und da, wie nichts sie aufwecken wollte, setzten wir eine Ligusterraupe auf ihre Halskrause. Aber die Raupe kroch in den Halsausschnitt hinein. Ruth schrie nicht einmal auf. Sie fiel um.«

»Die Hauptsache habt ihr vergessen,« bemerkte die Tante, -- »das, was die unartigen Mädchen entschuldigt und Ruths Schreck erklärt. Ruth war nämlich als Kind fest überzeugt davon, daß in den Raupen, Schlangen und allem Gewürm der leibhaftige Böse sitze. Sie steckte überhaupt immer voll von gottlosen Ammengeschichten. Weiß Gott, wo sie die auflas. In solchen Dingen ist Ruth immer so merkwürdig kindisch gewesen, und auch geblieben. Sie hat dasselbe Grauen unvermindert noch heute.«

»Aber es ist ihr seitdem alles aus den Augen geräumt worden, was sie daran erinnern könnte,« sagte der Onkel zu Erik.

»Das hätte es nicht dürfen,« entgegnete dieser bestimmt, aber sein Gesicht war sehr nachdenklich geworden. »Man kann mit Ruth nicht behutsam genug, aber gleichzeitig auch nicht fest genug umgehen, wenn man ihr nützen will.«

Er erhob sich, um Abschied zu nehmen.

Der Onkel schwieg einen Augenblick, zerdrückte stehend seinen Cigarettenrest auf dem Aschenbecher und sagte dann plötzlich herzlich zu Erik: »Wissen Sie, -- ich bin froh, ordentlich froh bin ich, daß die Ruth bei Ihnen ist.«

»Ich wünsche nichts lieber, als daß sie mir bleibt!« entgegnete Erik einfach.

»Ja, sehen Sie,« fuhr der Onkel fort, indem er dicht an ihn herantrat, »ich glaube, gerade bei Ihnen ist das kleine Ding endlich einmal vor die rechte Schmiede gekommen. Nach all ihren Irrfahrten. Und vor die rechte Schmiede, das heißt fast so viel wie: ~nach Hause~.«

»Aber, ich bitte dich,« fiel die Tante, unangenehm berührt, ein, »nach deinen Worten muß jeder denken, Ruth sei hier mißhandelt worden.«

»Ach, wieso denn mißhandelt,« sagte er verdrießlich. »Nein, gut behandelt, natürlich, wie sollte es denn anders sein? Aber wozu sollen wir's leugnen: Sie wissen sich besser um sie zu kümmern, als wir es verstehen. Neulich fühlte ich's schon, heute weiß ich's ganz deutlich. Ich ~freu'~ mich ja auch an ihr, -- ja, das thu' ich, weiß Gott, -- aber im übrigen: das Kind ~hat~ nichts davon. Das ist es nur, was ich meine.«

»Nun ja,« lenkte die Tante ein, »sicherlich müssen wir Ihnen dankbar sein. Aber sprich nur nicht so sündhaft. Es klingt ja geradezu so, als ob du Ruth los sein wolltest. Grüßen Sie das liebe Kind von mir. Und wenn sie erkranken sollte, komme ich ganz bestimmt hinaus und pflege sie.«

Erik versprach, das »liebe Kind« zu grüßen, das er ihr am liebsten nie wiedergegeben hätte. Er ging mit dem Onkel fort und erwog einen Plan, für den er ihn zu gewinnen hoffte. Sie waren beinahe Freunde geworden. --

Als Ruth im Laufe des Vormittags aufstand, sah sie Klare-Bels langen Stuhl schon am steinernen Springbrunnen aufgestellt. Ein Stück gestreiftes Segeltuch, das man zwischen den Obstbäumen angebracht hatte, schützte sie vor der Morgensonne.

Nach dem Gewitter schien sich das Laub ringsum wie durch einen Zauber entfaltet zu haben. Der Garten stand ordentlich grün da, und die letzten Blätter drängten sich aus der Knospe. Ruth ging langsam durch den Garten hin, und mit Entzücken hefteten sich ihre Augen auf die frische, sonnenwarme Schönheit um sie her und auf die kranke Frau, die inmitten derselben ruhte.

»Guten Morgen, Ruth!« rief Klare-Bel ihr entgegen und streckte liebreich die Hand nach ihr aus, »willkommen, mein liebes Kind! Du weißt wohl, wer ich bin? Ich konnte nicht zu dir kommen, als du die Nacht krank dalagst. Ich bin froh, daß du wieder gesund bist, und daß du nun zu mir kommen kannst.«

Ruth ergriff die kleine, weiche Hand, der man es ansehen konnte, wie rund und rosig, mit Grübchen über den Knöcheln, sie gewesen sein mochte. Und, einem raschen Gefühle folgend, beugte sie sich nieder und küßte die Hand. Sie blickte Klare-Bel mit einer Art von Ehrfurcht an, wie den kostbarsten Gegenstand hier im Hause.

»Erik und Jonas sind in der Stadt,« sagte Klare-Bel, »ich liege jetzt ganz allein hier. Willst du mir ein wenig Gesellschaft leisten, Ruth?«

Ruth nickte, noch immer ohne zu sprechen; sie war wie berauscht vom Frühling und von dem starken, frischen Duft, den alles um sie herum ausströmte. Am liebsten hätte sie aufgejauchzt.

»Ich werde hier sitzen bleiben,« erklärte sie und kauerte sich mit emporgezogenen Knieen auf den bemoosten Steinrand des Springbrunnens, aus dessen geborstener Wasserurne über ihr ein langes, dünnes Schlinggewächs sich schlangengleich herunterrankte; »denn hier ist es am allerschönsten in der ganzen Welt!«

»Sie übertreibt alles!« dachte Klare-Bel, sie heimlich betrachtend, fühlte sich aber in diesem Augenblick doch angenehm berührt. »Am Meer ist es jetzt noch viel schöner, Ruth,« sagte sie, »da, wo wir früher gewohnt haben, -- auf der kleinen Insel weit draußen. Bist du schon einmal am Meer gewesen?«

»Ja, mehreremale,« versetzte Ruth, »aber viel lieber wäre ich gerade da gewesen, wo Sie gewohnt haben, -- auf der kleinen Insel. Aber ich wußte damals nichts davon. Nein, ich wußte es nicht.«

Es kam ihr sichtlich ganz wunderbar und eigentlich unbegreiflich vor, daß sie jemals nichts davon gewußt haben sollte. Klare-Bel fand, sie spräche ganz wie ein Kind: etwas so Selbstverständliches mit einem so ernsten und bewegten Gesicht.

»Und Sie wissen alles darüber!« setzte Ruth mit demselben Ausdruck hinzu, »alles, ganz so wie es war. War es wunderschön?«

Klare-Bel war nicht redseliger Natur; sie sprach ebenso wenig, wie Erik viel sprach. Aber sie bekam große Lust, sich mit Ruth zu unterhalten.

»Soll ich dir davon erzählen?« fragte sie und sah sie lächelnd an.

»Ja!« sagte Ruth dringend, und ein Gefühl, mächtiger als nur Neugier, trat in ihren Blick, »aber alles! wie die Menschen waren, und das Leben, und das Haus, und das Meer, und auch die Schulkinder.«

Klare-Bel fand, daß man mit dem Hause anfangen müsse. Und nachdem sie beschrieben, wie dörflich-klein und doch wie wunderbehaglich es gewesen sei, trotz seiner niedrigen Balkendecke und der schmalen Fensterscheiben, die von der Salzluft immer beschlagen waren, -- kam sie auf die Menschen zu sprechen, die dort aus- und eingingen. Viele Menschen waren das, -- ein ganzes Volk schien es Ruth, -- und immer scharte Klare-Bels Erzählung sie um den einen, den sie in den Mittelpunkt stellte, um den einen, der mit ihnen alles teilte und alles that, und den das jüngste Kind und das älteste Weib mit dem gleichen Lächeln grüßten.

Ruths Augen blitzten. Was Klare-Bel erzählte, das glaubte sie wahrzunehmen, zu schauen, mitzuerleben; sie ergänzte unbewußt das Bild bis zur greifbarsten Deutlichkeit, indem sie es mit den Goldfarben übermalte, die Klare-Bel selbst ihr auf die Palette rieb. Und um dieses ganze Bild hörte sie unablässig das gewaltige Meer donnern und schäumen.

Sie roch die Salzluft und fühlte den feinen Meersand unter den Füßen knirschen; mit nachdichtender Schnelligkeit folgte ihre Phantasie den Andeutungen der Frau, die gar nicht wußte, wie liebevoll sie idealisierte, was sie Ruth beschrieb.

Als Klare-Bel geendet hatte, atmete Ruth tief auf mit lebhaft geröteten Wangen.

»O wie herrlich Sie erzählen,« rief sie dankbar; »ich möchte nichts andres thun, als Ihnen den ganzen Tag zuhören. Den ganzen Tag. Ach, das möchte ich auch erleben! Wie schön muß es gewesen sein!«

»Das war es auch,« bestätigte Klare-Bel zufrieden, der es selbst noch nie so schön erschienen war, wie heute während ihrer eigenen Erzählung. Von sich selbst hatte sie bisher noch gar nicht gesprochen, nur von Erik. Aber auf Ruths Ausruf fügte sie mit dem Stolz der Frau, die sich ihr Glück liebend verdient hat, hinzu: »Schön und auch schwer, Ruth. Denn es ist schwer, mit so vielen teilen zu müssen, die alle von demselben Rat und Beistand und Teilnahme wollen und ihn immer in Anspruch nehmen, -- ihn immer fortnehmen. Es ist nicht leicht, man muß bescheiden werden. Das würdest du erst lernen müssen.«

»~Das?~« sagte Ruth verdutzt, »nein, das möchte ich lieber nicht. Das hatte ich mir dabei gar nicht ausgewählt. Aber so unter den Menschen stehen und alles können, als ob man ein Hexenmeister wär' -- das muß herrlich sein. Es muß sein, als ob man plötzlich viele Menschen auf einmal wäre -- und dann auch noch mehr, als sie alle zusammen.«

Klare-Bel schwieg betroffen. Sie fühlte recht wohl die enthusiastische Bewunderung in Ruths Ton heraus, aber sie konnte nicht begreifen, wie dieser Enthusiasmus, weit davon entfernt, dem Bewunderten dienen zu wollen, sich einfach egoistisch an dessen Stelle wünschte.

Ruth vertiefte sich inzwischen ganz in das Bild, das sie sich ausgemalt. Nach einer kurzen Pause hob sie wieder an: »Und das war doch nur ein Dorf. Eine ganz gewöhnliche Insel. Ringsherum Wasser, so daß da alles aufhörte. Es hätte aber etwas noch viel Größeres sein können, nicht wahr? Vielleicht mit noch viel mehr Menschen darauf. Ich weiß nicht recht, wie. Aber ich denke mir: so stark sein, -- und dann etwas Gewaltiges thun dürfen. Es braucht nicht beim Dorf zu bleiben.«

Klare-Bel berührten diese Worte wunderlich. Sie dachte im stillen, das sei es vielleicht so ungefähr gewesen, was ihr Mann einst gewünscht und erhofft habe. Damals, als alles um sie her noch Zukunft und Hoffnung war.

»Es wäre am Ende auch nicht beim Dorf geblieben,« meinte sie und sah Ruth an, »daran waren nur die Verhältnisse schuld. Er hatte früher so große Pläne. Ach, was hatte er alles für Pläne! Aber dann kam das Unglück, daß ich liegen mußte. Und es kamen die Aerzte, die Reisen, die Operationen. Zuletzt kamen die Schulden. Da war es mit den Plänen aus. Das hat alles schrecklich viel Geld gekostet, Ruth. Und ganz umsonst.«

Ruth blickte aus weitgeöffneten Augen auf die Frau, die das so ruhig sagen konnte.

»Ich könnt's nicht überleben!« stieß sie entsetzt wider Willen hervor.

»Ach, mein liebes Kind! Das denkt man, wenn man noch so jung ist wie du. Dann aber lernt man, sich in das Schicksal und seinen Willen fügen. Sogar in das Schwerste: stillzuliegen und nicht mehr mit eigenen Händen sorgen zu dürfen für das Behagen derjenigen, die man liebt. Denn das ist das Allerschwerste, Ruth.«

Es klang so sanft und liebevoll, wie sie das auf Ruths unbesonnenes Wort sagte. Keine einzige Klage hatte sie für sich selbst. Sie beklagte es nur, den andern nicht mehr dienen zu können.

Aber Ruth fand, es sei beinahe gleichgültig, ob man in einem solchen Fall den andern noch dienen konnte. Was sie so entsetzte, war die Vorstellung, durch ein derartiges Unglück die Ursache zu werden, daß ein Andrer, Starker, Gesunder aufhören mußte, ~seiner~ Sache zu dienen.

Es verwirrte sie ganz, daß die sanfte kranke Frau ihr gar nicht leid that. Sie hatte das Gefühl: diese würde ihr schon leid thun, wenn sie nur erst Zeit hätte, an sie zu denken. Aber sie mußte immer an Erik denken. Und sie empfand Mitleid mit ihm, stürmisches Mitleid bis zum Weinen.

Klare-Bel lag gerade ausgestreckt und blickte mit ihren ruhigen blauen Augen in den klaren blauen Himmel hinauf. Sie dachte an das Glück, wie sie es hätte behalten mögen, -- so klar und blau und ruhig, wie der.

»Das wünschte ich dir,« sagte sie zu Ruth, die ganz verstummt war, »einmal so von ganzem Herzen jemand dienen zu dürfen, den du lieb hast. ~Dazu~ gesund zu sein, und schön und gut und klug obendrein! Gleichviel, ob er dann Großes oder Kleines in der Welt vollbringt, -- daran liegt's nicht! Das Lieben und das Dienen ist doch das Schönere. Namentlich für uns Frauen. Es ist viel schöner, als derjenige zu sein, dem es gilt. Das brauchen wir nicht zu beneiden.«

»Ach nein!« rief Ruth lebhaft, »es kann ja gar nicht möglich sein, daß es das Schönere ist. Der, dem's gilt, hat es besser. Sonst hätte Gott es ja schlechter als die Menschen!«

Klare-Bel warf ihr einen erstaunten Blick aus den blauen Augen zu, -- einen tadelnden Blick. Aber sie wußte nicht, was sie darauf erwidern sollte. Man mußte wirklich ziemlich viel Nachsicht haben mit Ruth. Klare-Bel fühlte sich nur sicher, so lange Ruth zuhörte. Sie hörte so hübsch zu. Aber sobald sie sprach, mußte man sich verwundern und eigentlich auch ärgern. Die war sicher mehr für Erik geschaffen als für sie. Er würde wohl aus ihr klug werden. Denn das war ja seine Spezialität.

Inzwischen war Jonas, lustig pfeifend, von der Straßenseite her in den Garten getreten, und man sah ihn, den Schulranzen auf dem Rücken, zwischen den Bäumen im Hause verschwinden. Als er wieder zum Vorschein kam, war der Ranzen abgeworfen, und in der Hand hielt er ein mächtiges Butterbrot, in das er hineinbiß.

Er lief auf seine Mutter zu, küßte sie, streckte Ruth die Hand hin und sagte: »Du, -- Sie -- haben --,« stockte und wurde rot.

»Du!« entschied Ruth ernsthaft und betrachtete ihn.

»Ja, nicht wahr?« meinte er fröhlich und nahm neben ihr aus dem Rande des Springbrunnens Platz, »denn jetzt sind wir ja Hausgenossen. Eigentlich Geschwister. Nicht wahr, Mama? Und Altersgenossen auch. Wie alt bist du denn?«

»In elf Monaten siebzehn,« sagte Ruth.

»Ich bin erst sechzehn,« gestand er betreten, aber dann klärte sich sein Gesicht auf, -- »das heißt jetzt. Aber in elf Monaten längst nicht mehr. Sogar schon eher. Jetzt solltest du ein Stück Butterbrot mit mir essen, denn es ist noch eine gute Stunde, bis wir Mittag bekommen,« fügte er hinzu und brach, im lebhaften Drang sein Brot mit ihr zu teilen, es in zwei Hälften.

»Ich mag nicht essen,« sagte Ruth und lachte über seinen Eifer.

»Dann bist du gewiß noch krank!« behauptete er, »aber das war auch ein rechtes Glück, weißt du, denn sonst wärst du ja gar nicht bei uns geblieben. Es war eine gute Idee von dir, so im Gewitter herumzulaufen. Denk nur! wo du so bequem gleich bei Papa hättest sitzen bleiben können.«

»Ja. Wenn ich sitzen geblieben wäre, wäre ich auch fortgegangen,« bemerkte Ruth tiefsinnig.

Jonas konnte sich diesen Fall nicht ganz klar machen, und so sagte er schnell. »Komm mit mir in das Gehölz, Ruth. Du kennst es noch gar nicht. Da sind so viele Nester. Und mitten hindurch fließt ein kleiner Bach nach dem Wiesengrund zu. Wir können leicht hinüberklettern; der Zaun ist nur niedrig.«

»Nein,« erwiderte sie, »gehe nur hinter das Gehölz. Ich muß jetzt hier bleiben.«

»Was willst du denn hier thun?«

»Ich muß nachdenken.«

»Nachdenken?«

Jonas sah sie etwas verdutzt an; es schien ihm jedoch eine Beschäftigung zu sein, die Respekt verlangte. So stand er seufzend auf und trollte sich ins Haus, denn er wußte nicht recht, wie er sich daran beteiligen könnte.

Ruth merkte nicht, daß er ging. Sie blieb mit emporgezogenen Knieen sitzen, die Arme auf die Kniee, und das runde Kinn auf die geballten Hände gestützt, wie auf zwei Säulen. So blickte sie angestrengt vor sich auf einen einzigen Fleck im Grase, wo eine weiße Gänseblume stand, und dachte mit Hingebung nach, gleich einem indischen Derwisch. Sie wußte ganz genau, wo sie stehen geblieben war, als Jonas kam und sie aufhören mußte.

Klare-Bel lag still und hatte die Augen geschlossen. Die Mittagssonne strahlte warm über den Bäumen, kein Lüftchen bewegte das duftende Laub. Ein paar gelbe Schmetterlinge flatterten naschend um die Frühlingsbeete, und zu Ruths Füßen zirpten die Heimchen laut und eifrig ihr Lied.

Ruth versank tiefer und tiefer in ihren Mittagssonnentraum. Wie in goldenen Lichtwellen wob er sich um die Gestalt, die Klare-Bels Erzählungen vor ihr heraufbeschworen hatten. Ein unklares Verlangen, halb Demut, halb Forderung, bemächtigte sich ihrer, diese Gestalt so lichtvoll, so schattenlos als möglich zu sehen, -- in einem warmen Glanze, der sie unter allen andern Wesen hervorhob. Warum? das wußte Ruth nicht.

Aber das wußte sie: in diesem Licht sahen die wirklichen Menschen, die sie sonst kannte, noch viel störender und sinnloser aus als bisher, -- fast als ob es nur lauter Leiber wären, in denen so gut wie nichts drinsteckte. Und die phantastischen Schattenbilder, die sie sich nach eingebildeten und fremden Menschen so schön entwarf, wie sie wollte, und wieder wegwischte, wann sie wollte, -- die sahen viel schattenhafter aus als bisher, ordentlich dünn waren sie geworden, und so durchsichtig, daß man meinen konnte, es seien nur Irrwische von Gedanken.

Ruth durchwanderte ihre ganze Welt wie der Schöpfer am sechsten Tage, fand aber nur das Chaos wieder. Und mitten darin den einzigen, wenn er wollte, alles beseelenden Menschen, den zu gestalten Phantasie und Wirklichkeit zusammenschmolzen. Es war, als stände er ihr ganz allein gegenüber in dieser einsamen, phantastischen Welt ihrer Träume, -- der ~erste Mensch~ am sechsten Schöpfungstage, unerkannt noch, und ein Wunder. Mit innerm Staunen stand sie still vor ihm, als müsse sie fragen. »Wer bist du? Wie kommst du hierher? Wie darfst du hier herrschen?« Er beschädigte ihre Gedanken so stark, er setzte sie so stark in Erstaunen, daß sie darüber sich selbst aus ihren Gedanken verlor und nur ihn anschaute. Es schien ihr notwendig, daß er etwas Besonderes, Merkwürdiges, ganz außer allem Vergleich Stehendes sei, wenn sie ihn da dulden sollte.

Und wieder erhob sich das unruhige Verlangen in ihr, Glanz auf Glanz, Licht auf Licht auf ihn zu häufen.

Nachdem Ruth lange Zeit stumm dagesessen hatte, richtete sie sich aus ihrer zusammengekauerten Stellung auf und ging langsam an die Gartenpforte. Die Arme über dem Zaun verschränkt, schaute sie die Straße hinab, die Erik entlang kommen mußte. Er kam bald. Sein erster Blick fiel auf ihr Gesicht und blieb aufmerksam und forschend darauf haften. Sie sah ziemlich blaß und schmal aus nach der Fiebernacht, aber der leidende Ausdruck von heute morgen war völlig aus ihren Kinderzügen verschwunden. Ein neuer Ausdruck, offen und verlangend, der Erik wohlgefiel, lag in ihren Augen.

Er nickte ihr mit einem Lächeln zu. Sie sprachen nicht miteinander, nur Ruths Hand schlich sich leise in die seine. Hand in Hand sah Klare-Bel sie auf sich zukommen.

»Wie lange hast du heute in der argen Sonne auf mich warten müssen, meine Arme!« sagte er zu seiner Frau, »nun sollst du auch keinen Augenblick länger daliegen.«

Damit schob er ihren Stuhl in die Nähe der Terrasse, hob sie heraus und nahm die kleingewachsene Gestalt so behutsam in die Arme, wie man ein Kind an der Brust bettet.

»Du allzuleichte Last!« scherzte er und sah heiter und belebt aus.

Klare-Bel lachte vor lauter Vergnügen und hatte die Arme um seinen Nacken geschlungen.

Ruth griff nach einem herabgeglittenen Kissen und folgte ihnen die Stufen hinauf. Am liebsten hätte sie ihnen den ganzen Stuhl nebst Zubehör nachgetragen, um dasselbe zu thun, was Erik that. Das Mitleid, das sie während Klare-Bels Erzählungen mit ihm empfunden hatte, war in nichts verflogen, -- und an dessen Stelle blieb die Bewunderung stehen. Es kam ihr jetzt ganz natürlich vor, daß die kranke Frau sich nicht als Last und Hindernis auf dem Wege des gesunden Mannes fühlte, sondern daß sie lachte und ihre Hände um seinen Nacken schlang.

Als Ruth ihren Platz bei Tisch einnahm, vergaß sie ganz, daß es heute zum erstenmal geschah, und daß sie erst gestern hatte weglaufen wollen. Sie fühlte sich als ein längst hierher gehöriger Hausgenosse, -- zufrieden und ohne weiteres eingereiht unter die übrigen.

»Von deinem Onkel bring' ich dir was mit,« sagte Erik, der sie zu Mittag neben sich gesetzt hatte, »nämlich die Erlaubnis, so lange hier zu bleiben, als du willst. Ich denke, wir antworten ihn vorläufig: den ganzen Sommer. Was meinst du?«

Sie nickte nur und sah glücklich aus. Wenn er aber nicht unablässig auf sie geachtet und ihr selbst vorgelegt hätte, so würde sie lieber keinen Bissen gegessen haben.

Als sie beim Kaffee waren, und die Kinder hinausliefen, blickte Erik seine Frau an und fragte: »Und nun, Bel, wie gefällt sie dir?«

»O Erik! mir gefällt sie gut für dich! Denn sie hat etwas so Unverständliches, finde ich. Das ist gerade was für dich. Was zum Raten.«

»Sie ist ein scheuer Vogel,« sagte er mit einem Lächeln, »und es ist noch nicht gewiß, ob ich sie eingefangen habe. Eine falsche Bewegung, -- und sie fliegt mir fort.«

»Ja, Erik, das denke ich mir nun wieder ungeheuer angreifend. Es macht doch unsicher. Förmlich schwindlich würde es mich machen. Wie ein konfuses Stickmuster.«

»Unsicher? Nein, Bel, im Gegenteil. Man wird sich wieder dessen bewußt, was man vermag -- ~ob~ man's vermag. Man sammelt die Kraft, -- die vergessene, eingerostete. Und so kommt man endlich wieder zur großen Sicherheit des Lebens und zum alten Glauben an sich selbst.«

»Ja, ja, Erik. Wenn nur alles gut geht.«

Er stand auf und legte herzlich seinen Arm um ihre Schultern: »Sorgenmütterchen! nur ein einziges Mal: laß die Sorgen, die grauen! Mir ist froh. Du sollst es noch sehen: an dem Mädel wächst mir mein Meisterstück!«

Sie seufzte und gab ihm im stillen ganz recht. Daß er Ruth zu sich nahm, das war ungefähr so, wie wenn ein Gelehrter eine recht unentzifferbare Handschrift irgendwo ausgräbt, -- meinte sie; an der liest er dann lieber und eifriger herum als am bestgeschriebenen Buch. Es war nun einmal nicht anders: darin steckte sein Talent und sein Beruf.

Erik ging fort; er wollte noch nach dem Bahnhof, um zu veranlassen, daß Ruths Gepäckstücke durch einen Bauernwagen herübergeschafft würden; der Onkel hatte sie bereits herausgeschickt.

Klare-Bel lag und dachte nach. Sie zwang sich dazu, an die Zeit zu denken, die sie sonst immer in ihrer Erinnerung zurückschob. Es war doch schön, daß Erik wieder so froh sein konnte und so voll von sanguinischen Hoffnungen. Das war doch besser und natürlicher für ihn, als diese langen, langen Leidensjahre, in denen nur der ~eine~ Gedanke ihn erfüllte: wie seine Frau wieder gesund zu machen sei.

Ein einziger jahrelanger Kampf, -- ein schmerzensreicher, gräßlicher.

Namenloses hatte Klare-Bel aushalten müssen um seiner Hoffnungszähigkeit willen, die nicht nachließ, nichts unversucht ließ, die noch ans Unmögliche anrannte, und mit unermüdlichem Trotz den alten Kampf immer wieder aufnahm. Es war nicht leicht, denn wegen einer geringen Herzschwäche durfte bei Klare-Bel die Narkose nicht angewendet werden. Aber immer wieder wußte er sie zu neuem Wagnis, neuer Qual zu überreden und mit seinem unbegrenzten Einfluß zu zwingen. Er war in diesem Kampfe zum Arzt geworden; was er früher aus Lust und natürlicher Begabung nebenher betrieben, wurde ihm Beruf. Seine ganze, ungeteilte Kraft warf er hinein: er wollte es nicht glauben, nicht dulden, daß ein einziger blöder und blinder Zufall auf Lebenszeit das Glück verschütten könne.

Und nun, da er's glauben und dulden mußte, war es doch hart, alles das umsonst geopfert zu haben, woran noch seine Hoffnungen gehangen hatten. Und wenn Ruth ihm nur eine davon zurückgab, wollte Klare-Bel sie lieben. Es war ja nicht mehr als eine kleine, späte und unscheinbare Blume für einen ganzen Strauß, den das Leben ihm schuldig geblieben.

Noch nie war das Klare-Bel so klar geworden, wie heute, seit dem Gespräch mit Ruth am Springbrunnen im Garten.

Jonas kam herein und setzte sich an das Fußende ihres Ruhebetts. Er griff nach einem Bund Garn, das Klare-Bel abzuwickeln begonnen hatte, und hielt es ihr auf den Fingern.

»Wird Ruth nun bei uns bleiben, Mama?« fragte er.

»Jawohl. Du hörtest es doch. Freut es dich nicht?«

»Ueber alles freut es mich. Nur werde ich mich jetzt so ganz umsonst anstrengen.«

»Wie meinst du das, mein Kind?«

»Ich meine: Papa wird Ruth ganz gewiß viel lieber haben als mich. Ganz gewiß. Sie ist sehr klug, -- meinst du nicht?«

»Das kann ich unmöglich wissen. Aber was ist das für ein Unsinn, Jonas. Weil Papa dich lieb hat, will er ja, daß du dich mehr anstrengst und besser vorwärts kommst.«

»Ach, Mama, ich strenge mich schon an so sehr, wie ich kann. Ich komme ja auch vorwärts. Aber Papa ist so schwer zufrieden zu stellen. Er ist der strengste Lehrer bei uns. Sie fürchten ihn alle. Aber ich am meisten. Von mir verlangt er am meisten.«

»Darüber solltest du froh sein. -- Mach nur jetzt keine Eifersüchteleien, Jonas; hörst du?«

Da lachte er über das ganze Gesicht, scheinbar völlig unmotiviert, so daß er wirklich einfältig aussah.

»Nein, Mama, das thue ich gewiß nicht. Wenigstens nicht so, wie du es meinst. Aber wenn es Ruth einfallen sollte, -- Papa lieber zu haben als mich -- --«

»Aber Jonas!«

Er ließ das Garn vom Finger gleiten, so daß es fast in Verwirrung geriet.

»Verzeih, Mama. Ich bringe es gleich wieder in Ordnung. -- Weißt du, du hattest eben ganz recht, als du sagtest, ich solle nur froh sein, daß Papa so viel verlangt. Das denkt sich nämlich Ruth angenehmer, als es ist. Sie wird das noch merken. Und ich werde nie etwas Unangenehmes von ihr verlangen.«

»Du bist wirklich ein recht dummer und unnützer Junge!« sagte Klare-Bel ärgerlich und sah sich ihren Sprößling genauer an. Er machte ein ganz treuherziges Gesicht. Das Lachen hatte sich in die Winkel der Augen verkrochen. »Wenn Papa so was hörte. Und

da wunderst du dich noch, wenn Papa Ruth dir vorziehen sollte.«

»Ich wundere mich ja gar nicht, Mama. Das kann ich ihm doch nie im Leben übelnehmen. Wie sollte Ruth ihm denn nicht besser gefallen als ich?«

»Wo steckt Ruth nur eigentlich?«

»Sie ist oben in die Giebelstube gelaufen, wo Gonne noch herumwirtschaftet. Um sich ihre Wohnung selbst herzurichten, sagt sie.«

Als Erik vom Bahnhof zurückkam, und Ruths Kopf oben aus dem offenen Fenster herausschaute, stieg er zu ihr hinauf. Das kleine, nach hinten zu abgeschrägte Gemach war schon in Ordnung. Außer dem heute beschafften Bett und einer großen Holzkiste, die durch zierlich gekrauste und gefaltete Mullvorhänge beinahe das Aussehen einer wirklichen Waschtoilette bekommen hatte, gab es jedoch hier noch nicht viel zu sehen. Ein Geruch von Seife und frisch aufgenommenem Oelanstrich machte sich bemerklich.

Ruth saß auf dem schmalen Fensterbrett, zu dessen Seiten schon kleine weiße Gardinen niederhingen; die Leiter lehnte noch daneben. Ein leichter Wind bewegte die Zweige der großen alten Ulme vor der Terrasse, so daß sie am Fenster auf und nieder schwankten und fast Ruths Gesicht berührten. Man sah von hier oben nur in die Wipfel der Bäume, und das, fand Ruth, sah lustig aus: wie ein grünes rauschendes Gewoge, von dem man sich einbilden konnte, es schwebe in der Luft, ohne Stamm und Wurzel. Wie viele Vögel mochten im Sommer darin nisten! Und unter dem vorspringenden Dach, gleich über dem Fenster, klebten zwei vorjährige Schwalbennester.

Als Erik auf die Schwelle trat und die Einrichtung des Zimmers bemerkte, fing er an zu lachen.

»Es ist wahrhaftig ein richtiger Karzer, wie gemacht für böse Kinder, die eine Strafe abbüßen sollen,« sagte er und blieb im Rahmen der Thür stehen, »oder für Durchgänger, die man mit Gewalt einsperren muß. Meinst du nicht, Ruth?«

»Nein. Es ist sehr schön!« versetzte sie mit Nachdruck und nahm es fast übel, daß er ihre Wohnung verspotten konnte; »es ist nur noch nicht fertig, und das ist das schönste. Wenn ich drin bin, wird es von selbst fertig. Es ist sehr schön. Ganz so, wie ich es haben will.«

»Das ist freilich die Hauptsache, meine kleine Königin,« gab er lächelnd zu und kam zu ihr ans Fenster; »als wir zuerst aus dem Auslande angereist kamen, da sahen die Stuben in unsrer Stadtwohnung auch nicht viel besser aus. Und es gefiel mir auch ganz gut. Man konnte so ganz von vorn und nach eigenem Ermessen anfangen.«

Sie wandte sich halb nach ihm um und sah ihn mit Interesse an.

»Ach ja!« sagte sie, »aber außerdem muß es doch schrecklich schwer gewesen sein, -- da von der kleinen Insel weg -- und hierher; weg vom Meer und von all den vielen Leuten?«

Er hatte seine Hände auf ihre schmächtigen Schultern gelegt und zwang sie mit sanftem Druck nach dem Rücken zu, denn es machte ihm heimlich Sorge, daß sie sich so gern vornüberneigten.

»Warum schwer?« fragte er dabei mit seiner ruhigen Stimme, »hier gibt es ja auch Buben und Mädchen genug zu unterrichten, -- schlimme kleine Mädchen mit ganz schlimmen Aufsätzen, wie du weißt.«

»Ach, -- die!« sagte sie im Tone tiefer Verachtung und zuckte mit den Achseln, »die sind's nicht wert.«

»Auch du?« fragte er zweifelnd und sah sie aufmerksam von der Seite an.

»Ja, auch ich,« meinte sie treuherzig.

»Du bist ja ungeheuer demütig heute,« bemerkte er, »allzu demütig, Ruth. Das ist nicht gut.«

»Warum ist nun das auch wieder nicht gut?« fragte sie zerstreut.

»Weil es nicht aus dir selbst herauskommt, Mädel. Nicht aus deiner Natur. Es ist, wie wenn jemand eine Stellung festhalten wollte, für die er sich verrenken muß. Das sollst du nicht thun.«

Sie erwiderte nichts darauf, vielleicht hörte sie kaum hin. Ihre Gedanken waren auf etwas andres gerichtet, das sie nicht anzubringen wußte. Nach einer kleinen Pause sagte sie leiser: »Sie sehen so froh aus. In den Augen -- und überhaupt. Warum?«

»Weil ich dich wieder habe, mein Kind,« entgegnete er ernst.

»Mich! aber all die andern?«

»Wen denn, Ruth?«

Nun hielt sie es nicht länger aus.

»Ich meine: bloß Buben und Mädchen zu unterrichten, die es gar nicht wert sind, und sonst nichts! Anstatt etwas ganz andres thun zu dürfen, etwas viel, viel Größeres, -- so groß wie ein Meer mit allen Schiffen darauf,« versuchte sie es auseinanderzusetzen und nestelte dabei, ohne es zu merken, erregt an seiner Uhrkette.

Er sah erstaunt auf sie nieder.

»Phantasierst du, Kind? Du sollst dem nicht so nachgeben,« sagte er eindringlich, »was hast du eigentlich zusammengedichtet? Du mußt es klar sagen können. Nun?«

»Es ist ja etwas Wirkliches!« rief sie schüchtern, »es ist gar keine Phantasie. Wir sprachen im Garten darüber, -- am Vormittag.«

»Mit meiner Frau?«

Ruth nickte.

»Sie hat mir erzählt. Von früher und von jetzt. Sie erzählt so wunderschön! Ganz wunderschön erzählt sie.«

»So. Thut sie das? Ader was hat sie dir denn erzählt?« fragte er, und sein Blick war forschend und gespannt.

»Alles. Und da, -- ja, da schien es mir so ganz entsetzlich, -- so ganz unmöglich schien es mir, daß nichts daraus geworden ist. Aus all den großen Plänen nichts geworden,« sagte sie leidenschaftlich, und ihre Finger umklammerten die Uhrkette, als müßte sie irgend etwas zerbrechen, »nichts als eine Schulstube. Und daß es immer so bleiben soll. Es kann ja nicht so bleiben.«

Sie sprach beinahe zornig, und in ihren Augen standen große Thränen.

Erik antwortete nicht gleich. Seine Hand hob sich und strich sanft hin über ihr loses weiches Haar, und als Ruth aufblicken wollte, da glitt die Hand tiefer und legte sich leise über die fragenden Augen. Er schaute über sie weg, hinein in die grünen rauschenden Baumwipfel, und kämpfte eine Erregung nieder. Ihm war seltsam zu Mute. Er wußte, daß das, was Ruth empfand, nicht von seiner Frau kam; weder die leidenschaftliche Auffassung, noch die phantastische Unklarheit des Bedauerten war seiner Frau möglich. Noch nie, seit er sich verheiratet, hatte er zu einem Menschen, hatte ein Mensch zu ihm von den Enttäuschungen seines Lebens gesprochen. Und da stand sie nun, die ihn seit vier Tagen kannte, in Zorn und Gram und Thränen und härmte sich um diese Enttäuschungen, als seien es ihre eigenen.

Als mehrere Minuten in Schweigen verstrichen, bückte Ruth den Kopf tiefer, und ihre Hand sank von seiner Uhrkette.

»Ich will es gewiß nie wieder sagen!« sagte sie leise, abbittend.

Er griff heftig nach ihrer Hand und preßte sie in der seinen zusammen.

»Du sollst mir immer alles sagen, alles, was dich beschäftigt,« versetzte er ruhig, aber seine Stimme klang verändert und gedämpft, »niemals sollst du Gedanken, die dich aufregen, vor mir verbergen, -- und nun gar Kümmernisse, mein Kind, -- solche kindischen und phantastischen Kümmernisse.«

Dann lehnte er sich gegen das Fensterbrett, vom Licht abgekehrt, das Gesicht im Schatten.

»Ich will dir eine Geschichte erzählen, Ruth; soll ich?«

Sie nickte gehorsam, ohne den gesenkten Kopf zu heben; man konnte sehen, daß ihr an dieser Geschichte nicht allzuviel lag, und daß sie sich als Kind behandelt fühlte.

»Es war einmal ein Mann,« begann er, »den gelüstete es sehr, ein großes, weites Feld zu bebauen, -- ein Feld, wohl so groß wie ein Meer. Denn er wußte, der Boden war gut, und nur der Arbeiter gab es noch wenige, -- viel zu wenige. Aber es kam anders, als er es sich gewünscht hatte, und an dem großen Felde durfte er so gut wie gar nicht mitarbeiten. Nur ganz fern, in einem äußersten

Winkel desselben, wies man ihm ein kleines Stückchen Erde an, wo er Kohl pflanzen konnte und Kartoffeln. Nur eben genug, um zu leben.«

Sie hatte längst die Augen mit aufblitzendem Verständnis zu ihm aufgeschlagen. Groß, ungeduldig hingen sie an seinen Lippen. Ihre ganze Seele war in diesen Augen.

»Und da --?« fragte sie atemlos.

»Und da,« fuhr er fort, »fand er eines Tages unter seinen Kohl- und Kartoffelstauden eine fremdartige kleine Pflanze. Von irgendwoher mochte ihr Samenkörnchen in diesen Boden gefallen sein. Es war nur ein unscheinbarer, zarter Trieb, dem man noch nicht ansehen konnte, was darin steckte. Aber vielleicht konnte er sich einmal zum Bäumchen auswachsen. Und wenn das gelang, -- wenn ein guter Gärtner an diesem Bäumchen unablässig seine Dienste that, und wenn das Bäumchen sich willig behandeln und biegen, pfropfen und beschneiden ließ, -- dann, -- ja, dann konnte es am Ende seltnere Früchte tragen, als irgend etwas, was sonst auf dem Feldwinkel wuchs.«

»Bin ich das Bäumchen?« fragte sie naiv und glitt leise vom Fensterbrett.

Er antwortete nicht, aber er zog sie näher an sich, so daß ihr Haar seine Schultern berührte. Auf ihrem Gesicht lag ein Ausdruck, der kein Lächeln war und kein Ernst, und doch wie ein gesteigerter Abglanz von beiden, der einer Ekstase glich. Er erinnerte Erik plötzlich an jenen Aufsatz mit der Ueberschrift: »Seligkeit!« Zum erstenmal erinnerte ihn dieses schmale Kindergesicht mit den beredten Augen und den geschweiften Lippen an die Verse im Schulheft.

»Möchtest du ein solches Bäumchen für den Gärtner werden, Ruth?« fragte er sie mit gesenkter Stimme.

Sie atmete tief auf.

»Noch lieber möchte ich der Gärtner werden,« sagte sie unerwartet, »aber es ist vielleicht fast dasselbe.«

III.

Jeden Morgen, ganz früh, noch ehe das Haus wach wurde, fanden Erik und Ruth sich im Studierzimmer zusammen. Sie standen beide ein paar Stunden zeitiger auf als sonst, um es zu können, und jeden Morgen nahm er mit ihr ihre Arbeit für den Tag durch, der er sie dann allein überließ.

Es war immer dasselbe Bild: Ruth war immer schon da, und stand, ihn erwartend, ins offene Fenster gelehnt. Sie horchte auf die kleinen Buchfinken draußen und zugleich, ob sein Schritt nicht über den Flur käme. Gewöhnlich sah sie ein bißchen blaß und bange aus, denn so übermütig froh sie auch tagsüber vor Erik sein konnte, -- als Lehrer fürchtete sie ihn. Und auch jetzt noch, wenn sie seinen Schritt im Flur vernahm, überfiel sie, wie am allerersten Abend, das Herzklopfen und die alte Schüchternheit.

Es war immer dasselbe: ohne daß sie sich nach ihm umwandte, trat Erik dicht an sie heran, bis ihr Rücken gegen ihn gelehnt war, dann schloß er ihre beiden Hände in den seinen zusammen, so daß sie wie eingefangen war zwischen seinen Armen. Es lag für sie darin nicht nur eine Liebkosung, sondern auch etwas zugleich Beschwichtigendes und Zwingendes, unter dem sie unwillkürlich stillhielt und sich sammelte. Und dann, ohne Zeitverlust oder überleitende Gespräche, nahm er sie sofort nüchtern und ernsthaft vor. So ging der Morgengruß unmerklich in die Morgenarbeit über.

Als Erik heute morgen die Thür zu seinem Zimmer öffnete, blieb er einen Augenblick überrascht stehen. Vor den Fenstern waren die weißlackierten Innenläden geschlossen worden, so daß die graue Regenluft draußen nur durch die Ritzen hereinschauen konnte; ein einzelnes Licht brannte mit trübem Schein auf dem Schreibtisch. Vor demselben saß Ruth, umgeben von Heften und Büchern, und schrieb, ohne auch nur aufzublicken.

Erik sagte nichts. Er schlug einen Laden zurück und öffnete das Fenster, so daß Luft und Licht in breitem Strom eindrangen, dann kam er an den Schreibtisch und blies das Licht aus, während Ruth verwirrt emporfuhr.

Er beugte sich zu ihr nieder, nahm ihr Gesicht zwischen seine Hände und blickte sie aufmerksam an.

»Du hast geweint. Worüber?«

Sie errötete und zauderte einen Augenblick.

»Ich mag nicht dumm sein!« rief sie dann außer sich mit sprühenden Augen.

Er lachte.

»Du bist nicht dumm. Habe ich das gesagt? Wenigstens nicht hoffnungslos. Solange ich dich nicht aufgebe, brauchst du es auch nicht zu thun.«

Er rückte ihren Stuhl vom Tisch ab und nahm ihr die Feder aus der Hand.

»Aber du darfst nicht nachts aufstehen und arbeiten. Nie ohne mein Wissen. Das ist Unfug. Wenn ich abends deine Arbeiten durchgesehen habe, dann sollst du aufhören.«

»Die Sonne hörte auch nicht auf,« sagte Ruth, »sie schien hell fast die ganze Nacht durch. Im Gehölz rief ein Kuckuck; die Drosseln vor meinem Fenster unterhielten sich. Da kam ich leise her.«

Erik griff über ihre Schulter nach dem Heft, in dem sie geschrieben hatte, aber Ruth hielt es zögernd und schüchtern fest. Man konnte ihr ansehen, daß sie in ihrer Erregung beinahe litt.

»Ruhig!« sagte er eindringlich und entfernte ihre Hand vom Heft.

Schweigend las er darin eine Zeit lang, während Ruth mit gefurchter Stirn dasaß, die Hände im Nacken verschränkt und ganz blaß.

Dann legte er ihre Arbeit vor sie hin.

»Das hast du gut gemacht,« bemerkte er, »hat es dir Mühe und Ueberwindung gekostet?«

»Ja,« gestand sie ehrlich, ohne ihre Haltung zu verändern, »aber es schadet nichts.«

»Nein. Es schadet nichts. Siehst du das nun selbst ein? Es konnte nichts helfen, mit dir zu treiben, was dir lieb und leicht ist; durch das, was deinen kleinen phantastischen Kopf am härtesten anmutet, durch das, was ihm am schwersten fällt, gerade da muß er hindurch.«

Er löste ihre im Nacken verschlungenen Hände und behielt sie in den seinen.

»Ich weiß, daß es manchmal ein harter Zwang war,« sagte er, »und du dein eigenes Wesen unterdrücken mußtest; es that weh, nicht wahr? Aber es mußte sein. Und nun, -- nun bekomme ich dich allmählich gerade so, wie ich dich haben will, Mädel. Ist es nicht schön?«

»Wunderschön ist es!« rief sie, mit leuchtenden Augen sich nach ihm zurückwendend, »das denke ich ja immer dabei, wenn es mir schwer fällt! Ich such's zu vergessen und denke mich nur hinein: wie wunderschön muß es sein, jemand, der ganz anders ist, gerade so zurecht zu kriegen, wie man ihn haben will!«

Ein Schatten von Enttäuschung ging durch Eriks Augen.

»Nur daran denkst du dabei, Ruth? Und ich glaubte, dich selbst solle es glücklich machen.«

»Das thut es ja eben!« erklärte sie erstaunt und stand auf.

»Was willst du nun heute morgen thun? Wir wollen in den Garten gehen. Es regnet nicht mehr. Oder meinst du, daß du schlafen könntest?«

Sie schüttelte lachend den Kopf.

»Ich möchte nicht, daß du später allein bleibst, ohne Beschäftigung und Morgenfrische,« sagte Erik; »arbeiten sollst du nicht. Vielleicht solltest du mit mir zur Schule kommen. Noch immer warten die Mädchen auf deinen versprochenen Besuch. Und in ein paar Tagen ist Klassenschluß. Es wird dich ablenken und zerstreuen. Und wenn es dich ermüdet, desto besser.« --

Gonne hatte auf der Terrasse den Frühstückstisch gedeckt, und Klare-Bel lag schon neben demselben in ihrem Stuhl, als Erik, Ruth und Jonas, erst auf wiederholte Rufe, aus dem Garten herankamen. Jonas sah ganz erhitzt aus, und der Strohhut saß ihm im Nacken; in seiner rechten Hand trug er einen hohen Eimer, den er von Gonne erbeutet hatte und jetzt auf die Stufen, die zur Terrasse führten, niedersetzte. Eine wohl zwei Fuß lange, stahlfarbene, bläulich glänzende Schlange wand sich darin.

»O pfui, Jonas!« rief Klare-Bel entsetzt, »wie magst du nur ein so greuliches Tier herbringen! Könnte sie uns nicht alle totbeißen, Erik?«

»Das kann sie nicht. Es ist eine Ringelnatter,« versetzte er lächelnd.

»Aber eine prachtvolle, Mama! ich fand sie hinter dem Gehölz, da wo der kleine Bach sich im Wiesengrund verläuft,« sagte Jonas voll Stolz und Bewunderung; daß er einen solchen Fund that, war ihm ein ganz unerwartetes Landvergnügen, er hatte eigentlich nur auf Raupen gerechnet, und höchstens auf eine Blindschleiche.

Ruth beteiligte sich nicht an der Unterhaltung über die Schlange, die Jonas gar nicht aufhören konnte zu bewundern, während sie Kaffee tranken. Seitdem sie im Garten Jonas mit dem Eimer in der Hand begegnet waren, verhielt Ruth sich ganz still. Sie hatte heimlich gehofft, Klare-Bel würde gegen die Schlange protestieren, aber die erkundigte sich ja nur danach, ob das Tier wohl jemand totbeißen könnte. Und das war an einer solchen Schlange doch wohl das Geringste, fand Ruth.

Jetzt gelang es der Ringelnatter, nach mehreren vergeblichen Versuchen, sich auf dem Boden des Eimers aufzurichten, sie wiegte rhythmisch ihren Oberkörper und guckte mit ihren kleinen klugen schwarzen Augen die Anwesenden an.

Klare-Bel blickte zufällig auf Ruth, deren Glieder ein Zittern durchlief, und die die halbgefüllte Tasse niedersetzte und erblaßte.

»Wirf das Untier fort, aber schnell, Jonas,« sagte seine Mutter rasch, »siehst du denn nicht, daß Ruth sich ängstigt?«

»Nein, lasse sie nur da,« fiel Erik ruhig ein, der Ruth die ganze Zeit über beobachtet hatte, »darauf soll keinerlei Rücksicht genommen werden.«

Dann wandte er sich in leichtem Ton an sie: »Liuba hat mir erzählt, daß du einmal wegen einer ähnlichen Kleinigkeit umgefallen bist. Strafe sie Lügen.«

»Hat Liuba gesagt: wegen einer Kleinigkeit?« fragte Ruth erstaunt. »Es war keine Kleinigkeit. Es war etwas fürchterliches, -- kalt und grausig, -- was so gewaltsam von außen kam, -- so, wie wenn man einen umbringt.«

»Um Gottes willen!« bemerkte Klare-Bel, »was kann denn das nur gewesen sein?«

»Eine kleine Raupe!« entgegnete Erik spottend.

Ruth wollte wahrheitsgemäß verbessern: »Eine große Raupe,« aber sicherer erschien es ihr, nicht noch ausdrücklich zu bestätigen, daß es nur eine Raupe gewesen war.

»Paß mal auf,« rief Jonas, »ich werde das Prachttier zähmen; Ringelnattern sind zutraulich und verständig, man kann sie gern um den Hals winden. Dann spielen wir ›Schlangenbändiger‹. Hast du je schon etwas so Schönes gehört? Ich bin der Schlangenbändiger. Da brauchst du dich gar nicht zu fürchten. Du siehst nur zu und -- und bewunderst mich.«

Erik lachte und griff ihm ins kurzgeschorene Blondhaar.

»Stopf deiner Eitelkeit den losen Mund,« warnte er, »denn schon ist die Zeit ganz nah, wo Ruth sich nicht mehr mit der Zuschauerrolle begnügen wird. Wo sie selbst, freiwillig, aus eigenem Antriebe, an die Schlange herantritt, sie in die Hand nimmt und sich auf den Körper hinaufkriechen läßt.«

Ruth hatte vergeblich versucht, ihn zu unterbrechen.

»Ich! Wann wird das sein?« fragte sie, ganz außer sich vor Erstaunen.

»Wann? vermutlich schon bald.«

»Nein! Nie!« versicherte Ruth, noch ganz fassungslos über seinen Irrtum, »ich würde mich ja immer fürchten.«

»Das würdest du wohl. Aber das ist noch kein Gegengrund. Es kommt vor, daß man stärker ist als die eigene Furcht, und daß man sie totschlägt.«

»Nun, Erik, das ist ein starkes Stück,« sagte Klare-Bel halblaut.

Jonas sah verdutzt aus, daß sein Vater so etwas im voraus wissen konnte, was doch Ruth selbst noch nicht wußte. Aber er begriff, daß Erik ihr etwas Unangenehmes geweissagt hatte, denn sie schauderte unwillkürlich zusammen.

»Weißt du was?« schrie Jonas ihr plötzlich zu, und der rettende Einfall verklärte förmlich sein Gesicht. »Ich weiß einen Ausweg: -- thu's eben nicht! Einfach! denke nur: du brauchst es ja einfach nicht zu thun!«

Er mußte sich von seinen Eltern auslachen lassen, und das Gespräch wandte sich andern Dingen zu.

Ruth saß regungslos da und blickte scheu nach dem Eimer. Wie gebannt, mußte sie den länglichen, schilderbedeckten, züngelnden Kopf ansehen, der sich dort herüberreckte. Es war, als grüße er sie. Es war, als schaue er nur gerade sie an. Nur sie ganz allein. Als sei sie ganz allein mit der Schlange.

Die kleinen runden schwarzen Augen schienen sich mehr und mehr zu erweitern, wie ein grausiger Höllenabgrund, in dem alles Unheimliche sein Spiel trieb. Und hinter dem Kopf mit den Augen hing das ekle, schlüpfrige Gewürm und wand sich ungeduldig. Es war ganz gewiß: die Schlange lauerte schon auf sie.

Sie sah doch wirklich so aus, daß man das Schlimmste von ihr denken konnte.

Ruth und die Ringelnatter maßen sich mit den Blicken.

Ruth errötete langsam, immer dunkler, ohne ein Wort zu sprechen.

Da, als Erik sich vom Frühstückstisch erhob, und Jonas wieder in den Garten laufen wollte, sprang Ruth hastig auf und sagte wild. »Dann lieber gleich!«

Die andern verstanden sie nicht recht, nur Erik, der sie unausgesetzt im Auge behalten hatte, entschlüpfte ein Laut der Ueberraschung.

»Jetzt gleich?« wiederholte er, »nein, mein Kind, das ist weder gut noch notwendig. Es wäre eine ebensolche Uebertreibung wie das mit dem Nachtarbeiten. Und nach dieser Nacht bist du mir jetzt nicht fest genug dazu.«

»Ich bin fest!« versicherte sie fast flehend, »aber warten kann ich nicht auf etwas so Grausiges! Ich kann es nicht so heranschleichen sehen, -- Tag für Tag, -- immer näher, -- immer gewisser; -- mit einer Schlange zusammenwohnen, vor der ich mich fürchte, -- und die mit der ganzen Familie immer intimer wird, -- -- und nur auf mich lauert, -- nein, das kann ich wirklich nicht!«

Erik lachte, sah aber dabei besorgt aus. Dies kam ihm ganz unerwünscht.

»Aber Ruth!« sagte er, »hat dich denn deine Phantasie mit Haut und Haar aufgefressen? Eine solche Kleinkinderangst legt man am sichersten in allmählicher Gewöhnung ab. Mir ist es lieber, wenn es allmählich geschieht. Ueberlege es dir! Denn, wenn du darauf bestehst, gibt es kein Zurückweichen mehr! Dann kein Spielen und Versuchen! Das würde ich nicht dulden. Deiner selbst mußt du sicher sein.«

»Ja!« behauptete Ruth, und die Stirn wurde ihr feucht.

»Willst du es trotzdem? Gut. Dann komm her.«

Erik beobachtete sie mit gespannter Aufmerksamkeit und trat zugleich von hinten an sie heran, damit sie sich mit dem Rücken gegen ihn lehnen mußte, wenn sie etwa »umfiel«.

Sie stand mit herabhängenden Armen da und machte ein entschlossenes, beinahe finsteres Gesicht. Als er sich aber nach dem Eimer bückte, und sie, dicht vor sich, die Schlange in seiner Hand sich winden sah, überfiel sie ein Schwindel.

Unwillkürlich schlossen und ballten sich krampfhaft ihre Hände, denen sie befahl, sich nach dem glatten Wurm auszustrecken; sie machte zuckend die Augen zu, und es fing an, ihr vor den Ohren zu sausen.

Da hörte sie Eriks ruhige Stimme: »Fürchtest du dich sehr?«

Sie nickte fast unmerklich.

»Dann wollen wir es lassen, mein Kind.«

Ruth öffnete erwartungsvoll und groß die Augen.

»Für immer?« fragte sie schnell.

Er mußte lächeln.

»Nein. Nicht für immer,« sagte er ruhig und freundlich, »aber es eilt nicht.«

Sie nahm sich zusammen.

»Dann jetzt gleich!« murmelte sie.

Und sie streckte den Arm aus und nahm ihm die Schlange aus der Hand. Bei der ersten Berührung erschütterte es ihren ganzen Körper wie ein elektrischer Schlag, sie warf den Kopf zurück und drängte sich hilfesuchend enger an Erik. Aber ihre Finger hielten dabei den langen, glatten Schlangenleib fest umspannt, und ohne einen Laut über die erblaßten Lippen zu bringen, sah sie mit weitgeöffneten Augen zu, wie die Ringelnatter sich an ihrem Arm hochstreckte, sich um denselben herumschob und den Kopf mit der feinen gespaltenen Zunge wiegend zur Seite niederhängen ließ.

Der Arm blieb ausgestreckt, als wäre er erstarrt. Und Ruth machte ein Gesicht dazu, als ob sie hingerichtet würde.

»Bravo!« sagte Erik, der seine Hände schützend und ermutigend um sie gelegt hatte, »auch das hast du gut gemacht, Mädel.«

Als er sie aber losließ und mit raschem Griff die Schlange wieder in den Eimer schüttelte, da taumelte Ruth.

»Nein, nein!« rief er heiter, »du mußt nicht denken, daß du jetzt noch ›umfallen‹ darfst. Damit ist es nun nichts mehr.« Und er schob ihr einen Stuhl zu.

Aber Ruth beachtete den Stuhl nicht, sondern ging, ohne aufzusehen, mit unsicheren Schritten an Erik vorbei, quer über die Terrasse und in den Flur hinein. Dort, so weit von ihm entfernt wie möglich, setzte sie sich in eine Ecke, hinter den Mantelständer, versteckte ihr Gesicht in den Mänteln, die dort hingen, und fing an zu weinen.

Erik sah ihr verwundert zu.

»Aber Ruth, du Narr!« rief er, und mußte doch lachen, »nun solltest du froh sein, und sogar stolz. Was kann es nützen, hinterdrein zu weinen?«

Sie guckte hinter dem Mantelständer hervor und blickte ihn vorwurfsvoll an.

»Ich thue mir so leid!« sagte sie und weinte weiter.

Jonas, der die ganze Zeit mit offenem Munde dagestanden, aber auf einen Wink seiner Mutter seine steigende Verwunderung für sich behalten hatte, sah auf diese Worte hin den Vater ebenfalls sehr vorwurfsvoll an. Er lief in den Flur, um Ruth zu trösten.

Eine Stunde später fuhr Ruth aber dennoch mit ihm und Erik zur Stadt.

Die Mädchen in der Schule warteten schon lange auf ihren Besuch. Es interessierte sie außerordentlich, daß Ruth jetzt bei Erik im Hause lebte, und in jeder Stunde erkundigten sie sich nach ihr bei Erik. Sie fanden, alles sei plötzlich so nüchtern geworden. Nur eine kleine Partei, freilich die beste, vermißte Ruth nicht. Das waren die Musterschülerinnen, die sich jetzt vor ihren Ausgelassenheiten sicher fühlten und durch keine argen Einfälle mehr in Versuchung geführt wurden. Aber die Stimmung blieb flau, und als es nun, so kurz vor den Ferien, zu regnen anfing, da verdüsterten sich die Gesichter auch der Fleißigsten.

So gab es doch eine gewaltige Freude, als heute, in der Freistunde, Ruth wieder auf dem Schulhof erschien, mit einem großen Regenschirm, unter dem ihr Gesicht vergnügt hervorschaute. Alle umringten sie, und der Lärm wurde so schlimm, daß im Hinterhause die Leute aus den Fenstern herabschauten, um zu sehen, was es gäbe, und warum die Schulvögel noch lauter zwitscherten als sonst.

Ruth war von ihnen die einzige Stille. Als sie so mitten unter ihnen stand, von allen bedrängt, da kam es ihr vor, wie wenn sie aus einer Weltferne zu ihnen zurückgekehrt sei, und sie wurde fast schüchtern. All das Viele, was sie zu erzählen hatte, all das Viele, worauf jene begierig waren, schmolz zu einem bloßen Blick und Lächeln zusammen, und es blieb nichts, als auf ihrem Gesicht der Ausdruck von Kinderglück, der an ihrer Statt erzählte.

Die Schülerinnen schoben sich an der Hauswand aneinander, wo das überragende Dach sie vor dem schwachen Sommerregen schützte, und wie damals, als Erik aus dem Klassenfenster auf sie niederblickte, fand Ruth ihren Platz wieder auf dem umgestülpten Wasserfaß.

Sie erschien den Mädchen verändert, ohne daß diese sagen konnten, wodurch. Denn wie ein Junge im Blusenkittel sah sie noch immer unter ihnen aus, und einen Zopf hatte sie ja auch noch nicht bekommen. Daß sie nicht sprach, entging ihnen vollständig; der in ihnen selbst aufgespeicherte Mitteilungsstoff brannte auf den Zungen, und, anstatt dessen, was sie von ihr erfahren wollten, erfuhr Ruth binnen weniger Minuten das Schicksal einer jeden einzelnen, von damals bis heute, nebst dem ganzen Gang der »öffentlichen« Angelegenheiten.

Das größte Ereignis stellten sie ihr in Person vor. Das war eine Braut. Eine wirkliche Braut aus ihrer Klasse. Ein großes, blondes Mädchen von frauenhafter Gestalt, mit ruhigen, freundlichen Gesichtszügen. Als Legitimation wurde ihr ein Ring von der linken Hand gestreift und seine Inschrift triumphierend vorgezeigt, -- der glatte goldene Traureif fiel Ruth in den Schoß.

Die Braut wehrte sich nur schwach dagegen, so als Gemeingut behandelt zu werden. Sie war begreiflicherweise mit ihren Gedanken längst aus der Schule heraus und fühlte sich mit deren Insassen nur noch durch das unendliche Interesse verbunden, welches ihr, ihrem Liebsten, und ihrem Glück wahrhaft glühend entgegengetragen wurde. Denn mit ihr betrachtete sich sozusagen die ganze Klasse als mitverlobt und an den Mann gebracht.

»Er ist dunkelhaarig!« erklärte das kleine blonde Gretchen, die besonders zärtlich an Ruth hing, »ach, Ruth, ein solcher, wirklicher Bräutigam bleibt doch das Allerhöchste. Denke dir nur, was man als Braut alles zu erzählen hat! Wenn wir so zusammensitzen, und sie spricht von ~ihm~ und dem Leben und der Ehe und der Zukunft, dann meint man, daß man in einer Stunde mehr erfährt als in all den Schuljahren mit ihrem Kram.«

»Wieso?« sagte Ruth, »sie weiß ja selbst noch nichts davon.«

Gretchen schwieg etwas betroffen.

»Nun, du bist auch nicht wenig prosaisch geworden!« fiel eine andre ein und lachte, »sie lieben sich ja doch! Findest du denn das nicht wunderschön?«

»Doch!« sagte Ruth und betrachtete nachdenklich den schmalen Goldreif in ihrer Hand; »vielleicht ist es wunderschön.« Dann gab sie ihn der Braut mit einem vollen Blick zurück und fügte hinzu: »Aber das Wunderschöne daran läßt sich ja doch nicht erzählen. Nicht wahr?«

Die Angeredete errötete etwas und sah Ruth erfreut an. Sie fühlte sich zum erstenmal zu dem beglückwünscht, was sie ganz für sich allein besaß, als Braut, -- was sie mit den andern nicht gemein haben konnte. »Es wäre eigentlich schöner gewesen, nicht so viel und so ausführlich mit allen darüber zu sprechen,« dachte sie plötzlich, mit Scham und Stolz. Und während sie den Ring überstreifte und Ruth anblickte, konnte sie dem Gedanken nicht wehren: »Diese hier ist gewiß die nächste Braut.«

»Ja, Ruth, du hast recht: zum Erleben mag es schmecken, zum Erzählen ist es fade!« rief die hübsche dunkle Wjera dazwischen, die schon immer zu den Kecken gehört hatte und sich jetzt aus allen Kräften gegen das Uebergewicht der »Brautschaft« in der Klasse sträubte, »was hattest du immer für herrliche Geschichten und Abenteuer für uns auf Lager! Und jetzt: der reine Hausfrauenzettel! Ich bin die einzige, die noch dem ›Edlen, Unglücklichen‹ nachsteigt.«

»Ist der noch da?« fragte Ruth.

»Ja, stell dir nur vor,« klatschte eine an Ruths Ohr, »sie macht förmliche Straßenbekanntschaften. Es hat schon einen Verweis gegeben.«

»Laß dir nichts in die Ohren blasen, Ruth,« unterbrach die Geschmähte sie, »es ist ja alles deine Schuld und dein Vermächtnis! Warum bist du auch fortgeblieben mit deinen schönen Freistundengeschichten?«

Ruth hatte ihren Kopf gegen die Hausmauer gelehnt und sah schweigend in den verregneten Hof. Gerade vor ihr erhob sich ein hoher Schornstein, dessen Rauchsäulen jahraus, jahrein die Mauern schwärzten und ihren Ruß auf den Schulhof niederstäubten. Gegenüber sperrte die mächtige gelbe Wand des Hinterhauses jede Aussicht ab. Die Luft war schwül; sie hatte es draußen im blühenden Juni gar nicht bemerkt.

»Wie ein Gefängnis!« dachte Ruth und sagte laut: »Das mit den Geschichten war ja nur ein Notbehelf. Phantastereien.«

»Wieso ein Notbehelf?«

»Würdest du uns keine mehr erzählen?«

Sie schüttelte den Kopf.

»Nein. Keine Phantasiegeschichten mehr. Nie mehr. Aber wenn man vor einer großen Mauer sitzt, dann malt man sich natürlich aus, was es hinter der Mauer gibt. Und wir wußten nichts, als daß es dahinter Männer gibt. Und da malten wir sie uns mit lauter Männern aus. Ihr wolltet es ja so.«

»Nun, und was? Was gibt es sonst noch dahinter?«

»Weißt du jetzt etwas davon, was es da gibt?«

»O!« sagte Ruth nur, aber ihre Augen öffneten sich groß und strahlten alle an, wie zwei unergründlich verheißungsvolle Glücksgeheimnisse, »dahinter gibt es das Leben.«

In ihrem Blick und Ausdruck lag etwas dermaßen Aufstachelndes, die Neugier und das Verlangen Aufreizendes, daß in diesem Augenblick den meisten selbst der »Bräutigam« schon etwas schal und abgestanden erschien. In den Gesichtern prägte es sich deutlich aus, daß ein neuer Hunger sich geltend machte.

»Wie kommt man denn über die Mauer?« fragte die unternehmende Wjera.

Ruth lachte.

»Man klettert eben hinüber,« sagte sie und lachte noch immer, »und dann geht man geradeaus, und noch rechts und nach links, ringsherum und nach allen Seiten. Bis man alt ist.«

»Nehmt euch in acht!« rief eine von den Musterschülerinnen warnend, »seht ihr denn nicht, wie sie euch foppt? Gerade so machte sie es immer mit euch. Sie spielt und phantasiert, und dann lacht sie uns aus, weil wir's ernst nehmen.«

»Nehmt's nur für Ernst!« sagte Ruth und gab sich vergebliche Mühe, den Schalk zu zügeln, der ihr im Nacken saß.

»Da sollen wir wohl zu Herrn Matthieux gehen und ihn bitten, uns auch über die Mauer zu helfen?«

»Das könnt ihr ja thun.«

»Der hätte wohl gerade Lust und Zeit dazu!«

»Die hat er gewiß,« versicherte Ruth; »und Lust hat er auch. Er hat alles, außer den Menschen, die dazu gehören.«

Sie sahen sich mit unsicheren und lächelnden Blicken untereinander an. Und dann auf Ruth, die gleichmütig dasaß, wie das verkörperte Behagen.

Die Spannung wuchs. Dies hier schien ihnen ihre schönste Geschichte zu sein.

»Sage mal: ist es auch gewiß, daß es dahinter angenehm ist? Hast du da auch gewiß nie etwas Unangenehmes vorgefunden?« fragte eine von ihnen vorsichtig.

»Nie!« behauptete Ruth, und es blitzte über ihr Gesicht, als ihr beiläufig einfiel, daß ihre Augen seit gestern noch nicht trocken geworden waren.

Die dünnstimmige Klassenglocke fing an zu bimmeln, und die Mädchen verließen den Platz am Brunnen.

»Du könntest Herrn Matthieux ja mal für uns fragen,« meinte die hübsche Wjera, »das kostet nichts.«

»Warum?« entgegnete Ruth; »es ist eure Sache. Laßt es euch nur was kosten.«

In aufgeregtem Meinungsaustausch drängten sie dem Hause zu. Darüber blieb es unbeachtet, daß Ruth ihnen nicht folgte. Ueber der Spannung, die sie hervorgerufen, war sie selbst vergessen worden. Als die Mädchen sich dann nach ihr umsahen, um einen gemeinsamen Heimweg zu verabreden, war Ruth verschwunden. Das letzte, was sie noch von ihr vernahmen, war ein Gelächter.

Erik brauchte an diesem Vormittag nicht ganz so viele Stunden zu geben wie sonst, denn mehrere Privatschulen hatten schon Ferien gemacht. So kam er bereits früh in seine Stadtwohnung hinauf, wo Ruth ihn erwarten sollte. Noch war nichts von ihr zu erblicken. Erik erledigte, was es hier noch zu thun gab, und kleidete sich um, froh, der heißen Uniform zu entrinnen. Als Ruth sich dann immer noch nicht melden wollte, öffnete er etwas beunruhigt die Thür zum Wohnzimmer und schaute hinein.

Da lag sie und schlief.

Sie hatte ihre kleinen Schuhe ausgezogen und unter einen Stuhl gestellt. Dann hatte sie sich, mit emporgezogenen Füßen, auf dem weißen Leinwandbezug des Sofas zusammengekauert. Den Kopf gegen das Seitenpolster gedrückt, schlummerte sie, mit ernstem Gesicht und schlafgeröteten Wangen, fest und eifrig, wie ein Kind.

Die Müdigkeit mußte sie beim Warten überfallen haben.

Aus dem grauen Regenhimmel stahlen sich durch die niedergelassenen Fenstervorhänge einzelne Strahlenbündel, in denen der Staub in breiten Wellen flimmerte und zitterte, und huschten über Ruths Gesicht. Ein leises Lächeln glitt mit den Sonnenstrahlen über dasselbe hin und blieb auf den Lippen stehen, wie im Traum. Dann, als die Sonne zudringlicher wurde, zog sie ein paarmal Stirn und Nase kraus, und endlich mußte sie heftig niesen.

Das Lachen breitete sich über ihr ganzes Gesicht. Lachend wachte sie auf und hörte Erik lachen.

»Ist es Morgen?« fragte sie verwundert und setzte sich auf.

»Nein. Es ist Mittag. Warum bist du denn den Mädchen so rasch weggelaufen? Sie fragten noch nach dir,« sagte er.

Ruth rieb sich die Augen.

»Ach so, die Mädchen. Jetzt weiß ich schon,« versicherte sie; »ja, mit den Mädchen ist es nichts. Glaub's nicht. Aber mir ist eingefallen: wenn man keine lebendigen Menschen aufbringen kann, -- dann gäb's am Ende auch noch ein andres Mittel.«

»Mädel! Schüttle den Schlaf ab. Träumst du denn noch?«

»Nein, nein. Kein Traum,« sagte sie eifrig, glitt mit den Füßen vom Sofa herunter, stützte die Arme auf den staubigen Tisch davor und drückte das Kinn auf die geballten Hände; »ich habe es mir nämlich so gedacht: wenn man zu den Menschen sprechen will, -- in sie hineinwirken, -- an ihnen was Großes schaffen, -- und man findet nicht recht die richtigen Menschen, die gut dazu passen würden, dann muß man es ~so~ machen: man muß sich etwas ausdenken, was man ihnen vor Augen stellt, -- so recht überzeugend und gewaltig vor Augen, bis sie Lust kriegen. Kann man das nicht? Warum nicht? Zu den Menschen vom Allerschönsten reden und nicht müde werden, -- bis sie Lust kriegen.«

Sie sprach rasch und belebt, mit wachen, glänzenden Augen, sichtlich bemüht, ihm etwas deutlich zu machen, das sie da, wie einen Traum, mitten aus ihrem Schlaf hervorgeholt zu haben schien.

»Wer soll das thun?« fragte er langsam, von ihrem Gesichtsausdruck wie gebannt, und trat heran an den Tisch.

»~Sie~ sollen es!« rief sie hell, »wer denn sonst? Sie haben mir immer gesagt: mit den Phantastereien ist es nichts, aber das Leben ist schön und weit. Ich glaub's ja! Ader nun weiß ich, wozu die Phantasiegeschichten gut sind, -- denn zu etwas sind die auch gut. Dazu, daß man sich ausdenken kann, was noch am Leben fehlt, und es hinzuthun. Am Leben und an den Menschen. Nicht wahr?«

Während sie sprach, ging Erik im Zimmer auf und ab. Ihm schien, als lausche er auf den kindlichen Ausdruck dessen, was er nur künstlich in sich selbst zurückgedrängt hatte. Es kam wieder und redete mit Kinderstimme zu ihm. Eine Reihe noch unklarer Pläne blitzte ihm durch den Kopf. Alte und neue durcheinander. Sie hatten immer nach Gestaltung verlangt. Und er, durch die Verhältnisse enttäuscht, hatte versucht, sie von sich abzuschieben, -- zu vergessen. Im vergangenen Winter hatte er sich in einen förmlichen Gesellschaftsrausch gestürzt, um sie zu vergessen.

Ruth saß und folgte ihm mit den Augen.

»Jetzt denkt er sich gewiß was aus!« dachte sie.

Mehrere Minuten vergingen in Schweigen. Beide merkten nichts davon, daß die Luft im Zimmer dick und staubig war, und ungezählte Mücken umherschwirrten.

Dann blieb Erik stehen, nickte zu ihr hinüber und sagte heiter: »Danke dir, Mädel. Erinnerst du dich, daß du mir etwas schenken wolltest, was ich eigentlich nie bekommen habe? Nun hast du mir aus deinen Phantasiegeschichten heraus doch etwas geschenkt. Zur guten Stunde.«

Sie sprang vom Sofa und kam auf ihren Strümpfen lautlos zu ihm.

»Ja!« sagte sie froh, »Sie wollten sie mir aus dem Kopf herausnehmen und alle für sich behalten. In den Kopf sollte nur lauter Vernünftiges hinein. Sie sagten damals: ›Nun sind alle deine Geschichten mein Eigentum, und ich kann mit ihnen machen, was ich will.‹ Und nun werden Sie etwas Schöneres damit machen, als ich's gekonnt habe.«

Sie hob den Kopf mit einem Ausdruck ungeduldiger Spannung und Erwartung, und dann fügte sie bittend hinzu: »Aber ich muß zuhören dürfen, wenn Sie sich was ausdenken! Darf ich zuhören? Werden Sie es mir erzählen?«

Erik blickte auf sie nieder. So kindhaft kam sie ihm vor, als sie so in Strümpfen neben ihm stand. Da reichte sie ihm noch nicht bis zur Schulter.

Wie heute morgen am Schreibtisch beugte er sich zu ihr, nahm ihr Gesicht in seine Hände und sah hinein in zwei strahlende, glückliche, bittende Kinderaugen.

»Wir werden es uns zusammen ausdenken!« sagte er. --

Klare-Bel hatte inzwischen Besuch gehabt. Als Erik und Ruth nach Hause kamen, stand eine Equipage vor der Gartenpforte. Der Kutscher wendete den leichten Wagen mit englischem Gespann und ließ die Pferde sich langsam, im Schritt, abkühlen.

Warwara Michailowna saß bei Klare-Bel in deren kleinem, behaglichem Gemach neben der Wohnstube. Sie war von ihrem erst kürzlich bezogenen Landhause, das etwa eine Stunde entfernt lag, herübergekommen.

Es waren meistens nicht nur konventionelle Besuche, die sie der kranken Frau machte. Sie kam gern, wie sie auch gern empfangen wurde: Sie empfand es wohlthuend an Klare-Bel, daß man deutlich fühlte: hier lag eine, der es wirkliches Vergnügen machte, einmal im Plauderton wieder etwas von der Welt draußen, von den Menschen und der Gesellschaft zu hören. Konnte sie auch nie wieder in das gesellige Treiben zurückgelangen, so kannte sie dergleichen doch recht wohl aus den ersten, beglückenden Jahren ihrer Ehe und sah es noch immer ein wenig im Glanze dieser Zeit. Und da war es nun eigentümlich: wenn man zu so einer sprach, dann ließ man unwillkürlich den schlechtesten Klatsch zu Hause.

Klare-Bel selbst erzählte zwar niemals viel. Aber Warwara wußte, daß es auch andern Bekannten gegenüber nicht geschah. Sie wußte: dies hier war wirklich eine Frau, die mit niemand intim zu sein vermochte, als mit ihrem Mann.

Was Warwara über Ruth und deren Anwesenheit im Hause erfuhr, fesselte sie im höchsten Grade und erregte sie beinahe. Als aber nun Ruth ins Zimmer trat, war sie enttäuscht.

Sie hatte unwillkürlich etwas Auffallendes erwartet.

Vielleicht einen wilden, interessanten Jungen in Mädchenkostüm, vielleicht auch umgekehrt ein rührendes, liebliches Kind, das sich schüchtern zurückzog, -- jedenfalls etwas ganz Eigenartiges. Nicht ein blasses, wohlerzogenes Ding, das sich für Warwaras im Salon geübten Blick von andern so jungen Mädchen durch nichts unterschied, als höchstens durch das geradezu Abgeschliffene, Formsichere und Unbefangene ihres Wesens einer Fremden gegenüber.

Nicht minder schnell war Ruth mit Warwara fertig: sie nahm diese ganz als eine von vielen und gab auch sich selbst so, wie eine unter den vielen, aus denen die Gesellschaft besteht.

Warwara zog sie ein wenig ins Gespräch und fragte, wo sie erzogen worden sei.

»Ich war an verschiedenen Orten,« sagte Ruth, »aber erzogen bin ich noch nicht.«

Man wußte nicht, war es bescheiden oder übermütig gemeint?

»Wenn die nicht durchtrieben ist!« dachte Warwara bei sich und musterte sie schärfer.

Bald trat Erik dazu, eine heitere Unterhaltung in Gang bringend. Warwara erzählte vom Rückgang einer Verlobung, deren Anzeige erst kürzlich auch hier eingelaufen war. Ein sensationeller Rückgang, denn die Braut hatte sich während der kurzen Verlobungszeit ganz eilig in einen andern verliebt.

Erik, der es nicht über sich vermochte, die humoristische Seite dieser Sachlage unbeachtet zu lassen, lachte laut.

Warwara sah sich nach Ruth um. Diese war hinausgegangen.

»Zufällig? oder ein Kunstgriff, um bei diesem Gespräch nicht hinausgeschickt zu werden?« fragte sie sich, »oder ist sie wirklich so kindlich, daß sie das gar nicht interessiert?«

Nachdem Erik über den betrübten Mienen der beiden Frauen wieder ernst geworden war, sagte er: »Ja, die armen Frauen! Wenn sie sich binden, haben sie allen Grund zu beten: Lieber Gott, hilf, daß ich eine gute Frau werde. Denn ihr einziger Schutz gegen sich selbst liegt in der That im rein gefühlsmäßigen Fortdauern ihrer Liebe, -- in der eigentlichen Gefühlstreue. Sie können natürlich auch aus Pflichtstrenge festhalten, aber das ist dann ein verkümmertes Leben.«

»Sie meinen, der Mann bedarf eines solchen Gebetes nicht,« bemerkte Warwara, ohne ihre Ironie zu verbergen.

Er sah sie ganz unbefangen an. »Nein,« sagte er; »ich glaube, der Mann ist in diesem Punkt, wie in so vielen andern auch, durch seine Natur besser geschützt. Nicht gegen die Untreue der Sinne. Nicht gegen den Wechsel des Liebesgefühls. Aber gegen das bewußte innere Loslassen desjenigen Wesens, an das er sich gebunden, -- nein: ~das er an sich gebunden~ hat. Das ist's!«

»Das ist originell. Sie vindizieren da dem Manne eine Kraft des Pflichtbewußtseins, einen Edelmut des Mitleids, den ~wir~, -- die Frauen, -- nicht --«

»Ach nein, empören Sie sich nur nicht. Kein Pflichtbewußtsein: nur ein Glücksbewußtsein mehr, als ihr es habt. Keinen mitleidigen Edelmut: nur einen begehrlichen Hochmut, den ihr nicht besitzt. Der Mann, der für immer ein Weib an sich und auf sich nimmt, genießt neben dem Liebesglück noch ein andres, spezifisch männliches Glück: er legt seine Hand bewußt auf dieses ganze ihm zugehörige Dasein und sagt dazu: ›Mein‹. Ihm bedeutet sein Glück durch das Weib dreierlei: lieben mögen, -- verantworten wollen, -- herrschen dürfen.«

Warwara schüttelte sich.

»Gott erhalte Ihnen Ihre Arroganz!« sagte sie; »mir jedoch ist wahrlich die Vorstellung lieber, nach welcher die Frau des Mannes Königin ist.«

»Sie sehen, -- ich sage noch mehr: sein Königreich,« versetzte er lächelnd, »daher gibt sie ihn eher preis, als er sie. Für sie gibt es eben ihm gegenüber Aufstand, Empörung, Revolution, -- was alles ganz heroisch aussehen und sehr verführerisch wirken kann. Für den Mann hingegen wäre untreues Preisgeben seines eigensten Reiches etwas, was ihm wider die Scham geht.«

Warwara lachte ihm ins Gesicht.

»Und das sind Sie, der für alle möglichen modernen Entwickelungskämpfe, und auch für die der Frauen, so gern eintritt!« rief sie; »es ist eine schauderhafte Inkonsequenz und ein Selbstbetrug obendrein! Denn wenn Sie sich nun in eine solche entwickelte Zukunftsfrau verliebten, die nicht mehr so mittelalterlich denkt, und sie ~nicht unterkriegten~?«

»Das würde ich doch!« sagte Erik. »Sonst würde ich mich vielleicht für sie begeistern, sie bewundern, fördern, als meinen Kampfgenossen achten, -- aber lieben, -- wie sollte ich das? So wenig, als wenn ich ein Weib, oder sie ein geschlechtsloses Wesen wäre. Ich kann mir vorstellen, daß der Mann jede Herrschsucht vollständig ablegt um einer Sache willen, die er über sich stellt. In der Liebe -- nie! Und ein Weib, das diesem Instinkt nicht entgegenkommt, -- wirkt nicht als Weib.«

»Und dieser Widerspruch sollte in der Natur selbst liegen? Nein, nur in eurem jahrhundertelang großgenährten Dünkel,« versetzte Warwara entrüstet und wandte sich zu Klare-Bel: »Was sagen Sie nur zu einem solchen Mann? Wir sollten uns für alle Zukunft unter den Mann stellen, wenn wir lieben?«

Klare-Bel antwortete etwas unsicher: »Ich glaube, das thun wir, nicht weil wir unter ihm stehen. Sondern weil wir glücklich sein wollen.«

Alle drei fingen an zu lachen. Warwara erhob sich, um nach Hause zu fahren.

»Nun sollt' ich hiervon eigentlich genug haben,« bemerkte sie gut gelaunt zu Erik, »aber von meiner kleinen Nichte in der Mädchenschule erfuhr ich, daß diesmal Sie bei dem feierlichen Schulschluß die übliche große Rede halten werden. Da komme ich hin. Damit Sie doch wissen: Eine sitzt da und verspottet Sie. Und hübsch klingen wird es sicher. Ich habe nämlich schon immer Ihre Toaste in Gesellschaften so gern gehabt.«

Erik mußte lachen.

»Sie sollten mich nicht so gewaltsam daran erinnern, daß unsre schönsten Reden für Toaste genommen werden,« versetzte er, »und daß fast die einzigen aufmerksamen Zuhörer, die wir außer den Schulkindern auftreiben können, die gelangweilten schönen Frauen unsrer oberflächlichen Gesellschaft sind.«

»Liebste, jetzt sind Sie Zeugin, daß ich mich zu rächen habe,« sagte Warwara gekränkt zu Klare-Bel; »ich möchte nur wissen, ob's ihm nicht weh thäte, wenn die schönen Frauen alle wegblieben. Ich glaube, dieser Barbar würde dann ~Sie~ auf den Rücken nehmen und zur Zuhörerschaft unter seine Schulkinder setzen, die ihn alle fürchten wie das Feuer.«

»Das wird wohl nie geschehen,« meinte Klare-Bel etwas betrübt.

»Doch! doch! Kein Mensch kann in die Zukunft sehen. Wir werden jetzt, auf Grund einer Konsultation mit dem Professor, eine Behandlung meiner Frau durchführen, die Wunder verspricht,« sagte Erik zu Warwara und geleitete sie an ihren Wagen.

Jonas war später nach Hause gekommen, als Erik mit Ruth, und kam seltsamerweise erst zum Vorschein, als der Besuch fortgefahren war, und man sich schon zu Tisch setzte.

Die Zwischenzeit hatte er im hintersten Winkel des Gartens unter den tropfenden Bäumen verbracht, im Kampf mit einem großen Entschluß. Seine Ringelnatter war mit ihm, sie hing ihm melancholisch um den Hals, als wisse sie schon, daß ihr etwas sehr Unangenehmes bevorstehe. Noch einmal hatte er sie liebkosend in die Arme genommen, sie gestreichelt und zärtlich an sich gedrückt, noch einmal in ihrem kostbaren Besitze geschwelgt. Dann hatte er sie totgeschlagen.

Um es zu thun, mußte er sich Mut einsprechen und sein Herz verhärten. Er mußte sich vorstellen, daß er wie ein neuer Herkules sei, der die Hesione von einem Meerungeheuer erlöst, oder noch lieber wie Perseus, der sich seine Andromeda erobert. Aber diese Vorstellung verfing nicht recht. Seine arme Ringelnatter sah gar nicht aus wie ein Meerungeheuer; Ruth verkannte sie nur. Das Tier blickte ihn mit seinen schwarzen Aeuglein so beweglich an, und er hatte es so lieb.

Da ging ihm ein altes Märchen tröstend durch den Sinn, von einer Schlange mit einem Goldkrönlein auf dem Kopf; wer die totschlug, dem verwandelte sie sich in eine liebreizende Prinzessin. Er wußte nicht mehr, ob es sich genau so verhielt, aber es gefiel ihm. Und seine Prinzessin saß und wartete gewiß schon darauf.

Nachdem Jonas den Mord vollbracht hatte, wandte er sich mit rotem Gesicht ins Haus. Es war ein ganz ungeheures Opfer, fand er, was sie da beide Ruth gebracht hatten, er und die Ringelnatter. Denn die Schlange blieb nun tot, und er hatte sich über sie fast ebenso gefreut, wie über ein Reitpferd.

Und nun sprach Ruth bei Tisch immer von den albernen Schulmädchen, die er nicht leiden konnte. Es ärgerte ihn, daß sie heute in die Freistunde gelaufen war, denn bisher besaß sie an ihm ihren einzigen Spielgefährten, und in diesem Punkte verstand Jonas keinen Spaß.

Noch saßen sie beim Mittag, als ein Eilbote kam und ein Telegramm für Erik überbrachte.

Erik erbrach es und überflog den Inhalt, dann schob er seinen Teller zurück und trat mit dem Papier ans Fenster. Man sah ihm an, daß es eine freudige und ihn bewegende Nachricht war, die er erhalten.

»Fast ein ganzer Brief! An der Grenze aufgegeben,« sagte er; »denke dir, Bel, mein alter Freund Bernhard Römer ist hierher unterwegs. Siebzehn Jahre haben wir uns nicht gesehen. Oder noch länger? Damals waren wir beide noch Studenten! Erinnerst du dich seiner?«

»O ja, Erik! Wie sollte ich den vergessen! Denn mit ihm war es ja, daß du immer noch so große Zukunftspläne machtest. Ihr wolltet alles am liebsten auf den Kopf stellen. Ja, so jung wart ihr damals. Was ist Römer denn eigentlich geworden?«

»Er ist Professor der Medizin an der Heidelberger Universität. Schrieb mir noch manchmal in frühern Jahren.«

Ruth hatte aufgehört zu essen und sah mit großen Augen zu Erik hinüber. Bei dem Wechsel in seinem Mienenspiel und bei Klare-Bels Worten war es Ruth, als stiege plötzlich eine ganze, fremde und ferne Vergangenheit zwischen ihnen auf. Eine Vergangenheit, bei der sie nicht zugegen gewesen war. Ueberhaupt noch nicht auf der Welt! Es schien ihr ganz unmöglich.

»Wird er hier herauskommen?« fragte sie leise.

»Das wird er leider nicht. Er reist nur durch. Sein Ziel ist Moskau. Dort ist irgend eine Aerzteversammlung. Morgen früh am Bahnhof werde ich Näheres erfahren. Ob er seine Frau wohl mitgebracht hat?«

»Zu einer Aerzteversammlung?« bezweifelte Klare-Bel.

»Warum nicht? Ich glaube, sie sind in ihrem geistigen Leben eng verwachsen. Römer heiratete sehr jung, die Frau machte seine ganze Sturm- und Drangperiode noch mit durch. Das gab ihrer ganzen Ehe den Charakter.«

»Haben sie keine Kinder?« fragte Klare-Bel, die dieser Punkt besonders zu interessieren pflegte.

»Ich glaube nicht.«

»Keine Kinder?« wiederholte Klare-Bel im Tone des Bedauerns. Nichts war ihr an ihrem Leiden so hart erschienen, wie der Umstand, daß sie nicht wieder Mutter werden konnte; »das ist doch eine traurige Ehe, so zu zweien.«

»Soviel ich mich erinnere, haben sie nicht immer zu zweien gelebt. Sie hatten wiederholt ein junges Mädchen bei sich, das an der Universität studierte.«

»An der Universität studierte? Können junge Mädchen das?« erkundigte sich Ruth erstaunt.

Erik blickte sie mit einem Lächeln an.

»Jawohl. Solche junge Mädchen wie du,« sagte er; »es steht dem ja nichts im Wege, daß du eines der nächsten Hauskinder bei Römers wirst. Hast du Lust dazu?«

Er sagte es scherzend, aber der Blick, mit dem sie ihm antwortete, war so ernst, daß er ihm im Gedächtnis blieb.

Erik setzte sich an den Tisch zurück und plauderte mit seiner Frau von alten Zeiten. Jonas fand, nun könnte Ruth mit ihm hinausgehen, aber sie blieb sitzen und hörte zu.

Draußen hatte es angefangen, stärker zu regnen; Jonas lehnte in der Hausthür an der Terrasse und schaute prüfend hinaus. Als Ruth endlich vom Mittagstisch aufstand und in den Flur trat, bemerkte er: »Wenn wir doch wenigstens bei Regenwetter ›Mann und Frau‹ spielen wollten. Das paßt so gut fürs Haus. Denn wenn die Sonne scheint, thust du es doch nicht. Und dann ist es auch etwas, was du bei deinen albernen Mädchen nun einmal nicht haben kannst.«

»O doch!« versicherte Ruth und schwang sich auf das Geländer der schmalen Holztreppe, die nach ihrem Giebelstübchen hinaufführte, »das haben wir im Schulhof oft genug miteinander gespielt.«

»Das muß aber eine schöne Wirtschaft gewesen sein, ohne einen wirklichen Jungen!« meinte Jonas verächtlich. »Und ich möchte doch so viel lieber dein Mann sein, als der Mann in all den Räubergeschichten, bei denen ich mich immer so anstrengen muß.«

»Aber ich möchte nicht deine Frau sein,« sagte sie kaltherzig und saß und schaukelte mit den Füßen, »und dann wäre das auch noch viel anstrengender für dich. Sei doch froh, daß du bei alledem jedesmal die Hauptperson und der Held bist.«

»Nein, das bist du eben immer!« warf er ihr mißmutig vor.

»Nein, Jonas, das ist bestimmt nicht wahr. Du bist es ganz allein. Warst du nicht erst gestern der Egmont? Und neulich --«

»Ja, im Anfang!« unterbrach er sie gereizt; »aber wenn du mir alles immer erst vorsagst und womöglich auch noch vormachst, dann bin ich es ja gar nicht in Wirklichkeit, sondern nur du.«

»Ich kann doch nichts dafür, wenn du dumm bist.«

Jonas schwieg gekränkt. Wenn sie wüßte, wem sie das sagte; -- wenn sie wüßte, daß er freiwillig darauf verzichtet hatte, ihr seine Ueberlegenheit zu zeigen, sie in Furcht zu versetzen, sie zum Bitten und Schmeicheln zu bewegen! Denn, hätten sie

»Schlangenbändiger« gespielt, da wäre er doch wohl der Herr gewesen. Und sie war so dumm, ihm zu glauben, die Schlange sei wirklich entschlüpft.

Jonas brannte die Zunge, Ruth von seinem Opfer zu erzählen. Aber er fand, das verbiete ihm sein Mannesstolz. Lieber noch wollte er sich die Zunge abbeißen, wenn die Schwatzlust zu groß wurde.

»War ich Egmont, so hättest du mein Klärchen sein müssen,« sagte er; »warst du es etwa?«

»Nein, natürlich nicht. Dazu kam ich ja gar nicht. Denn allein hättest du ihn doch nie herausgebracht. Und er ist doch das Wichtigste, wie du dir denken kannst. Das Klärchen kann man streichen.«

»Ich habe aber keine Lust, mich zu deinem Hampelmann herzugeben! Sei meine Frau!« schrie er ärgerlich und stampfte mit dem Fuß auf.

Ruth war vom Geländer herabgeglitten. Sie stellte sich ans niedrige Flurfenster, an dem der Regen herunter rieselte, und drückte ihr Gesicht platt gegen das Scheibenglas, so daß es sich satyrhaft verzog. Wenn Jonas wütend wurde, dann überschlug sich jedesmal seine Stimme: sie schwankte immer zwischen zu hoch und zu tief. Das brachte Ruth immer zum Lachen.

Da riß Jonas seine Mütze vom Mantelständer und stürzte hinaus.

»Lauf nur zu deinen albernen Mädchen!« rief er grimmig, »ich bin ein Junge!«

Am Ende war Ruth gar nicht das Ideal einer Frau, wie er sie brauchte. Andromeda hatte sich bereit erklärt, ihrem Erretter als Sklavin durch alle Länder zu folgen. Ruth würde so etwas nie thun, es würde ihr gar nicht einfallen, -- davon war er fest überzeugt.

Von der Terrasse aus steckte Jonas seinen Kopf durch das offene Fenster des Wohnzimmers und fragte, ob er noch bis zum Abendthee einen Kameraden aufsuchen dürfe.

Klare-Bel, die neben dem abgeräumten Tisch lag und in Lenneps Novellen las, blickte bei seinen Worten verwundert aus.

»Es ist nur gut, daß er noch an so was denkt,« bemerkte sie, als sein Kopf vom Fenster verschwunden war, »denn jetzt denkt er Tag und Nacht nur noch an das Mädchen, Erik.«

»Strohfeuer!« versetzte dieser.

Er stand und schaute verträumt hinaus. Seine Gedanken weilten noch in der Vergangenheit. Seine Frau nahm den morgenden Tag nur als eine willkommene Zerstreuung, und darüber freute sie sich für ihn. Ihm war es mehr als das.

»Findest du, es schadet nichts?« fragte Klare-Bel besorgt: »aber du meintest doch selbst, Jonas sei flüchtig und zerstreut im Lernen geworden.«

»Das ist er wohl ein wenig, aber was ihm an Schulweisheit vielleicht dadurch abgeht, erhält er tausendfach wieder in glücklicher Anregung, die seine geistigen Kräfte belebt und aufschüttelt. Das ersetzt ihm keine Schule.«

»Er ist freilich noch wie ein Kind. Aber Jonas ist anhänglich. Wenn er nun sein Herz so ganz an sie hängt --?«

»Dann laß ihm diese Erinnerung, Ruth begegnet zu sein. Er kann es an nichts Besseres hängen, Bel.«

Sie schwieg darauf. Das holländische Novellenbuch entglitt ihren Händen. Sie faltete sie im Schoß.

»Wie hoch er sie stellt!« dachte sie im geheimen erschrocken.

Es war ein stiller Tag, der nächste. Weil Erik nicht nach Hause kam. Wie ausgestorben schien das Haus, weil man seinen Schritt und seine Stimme darin nicht hörte.

Er würde wohl erst mit dem letzten Nachtzug heimkommen, meinte Bel. Nachts ließ er sie gewiß nicht gern auf dem Lande allein.

Jonas schlich übler Laune im Hause umher. Nach dem gestrigen Streit fühlte er einen heftigen Drang nach einer ausgiebigen Versöhnung nebst darauf folgendem unzertrennlichen Beisammensein. Aber dafür war Ruth heute nicht zu haben. Den Streit hatte sie rein vergessen. Und auf alle seine Vorschläge, etwas Gemeinsames zu unternehmen, entgegnete sie nur ihr wohlbekanntes stereotypes: »Ich muß nachdenken.«

Und Jonas wußte schon, daß sie dann für ihn so gut wie verloren war.

Ruth dachte immerfort, unablässig über ein und dasselbe nach. Sie folgte in Gedanken Erik in die Stadt, an den Eisenbahnzug, der ihm den Freund bringen mußte, und versuchte, sich in das Wiedersehen hineinzuversetzen.

Als Klare-Bel ihm am Morgen beim Weggehen zurief: »Adieu, Erik, amüsiere dich gut!« da hatte Ruth beinahe betroffen aufgeblickt. Es kam ihr vor, als habe Erik etwas so Ernstes und Herzbewegendes vor. Selbst sein Gesicht schien ihr seit gestern verändert. Unter allem, hinter allem, was er in gewohnter Weise sprach oder that, fühlte Ruth es heraus, wie eine ganze Welt von aufgestörten Erinnerungen unaufhörlich in ihm raunte und redete. Keine Erinnerungen aber, die ~amüsieren~, -- sondern solche, die gewaltsam zurückzerren in eine Vergangenheit, von der die Gegenwart verdunkelt wird.

Auf dem Garten lag heute freundlicher Sonnenschein. Klare-Bels Stuhl war auf die Terrasse geschoben worden; unten konnte sie nicht bleiben, weil Erik fehlte, um sie wieder heraufzutragen. Ein warmer Sommerduft stieg von draußen auf; Flieder und Goldregen waren am Verblühen, und auf den Beeten öffneten sich die roten Rosen. Baumwipfel und Büsche drängten sich jetzt so dicht ineinander, daß es fast schon zu viel Laub und Schatten ums Haus gab. Der Sommer barg es ganz in seinem warmen Dunkel, und von der Straße gesehen nahm sich der Garten jetzt aus wie ein großer grüner Farbenklecks.

Als der Abendthee auf der Terrasse getrunken wurde, fiel es Klare-Bel doch auf, daß Ruth wie geistesabwesend dabei saß.

»Es ist doch, als könnte sie es gar nicht mehr ertragen, daß Erik sich mit andern Menschen beschäftigt als mit ihr; am liebsten würde sie ihm keine Zerstreuung mehr gönnen, diese arge kleine Egoistin,« dachte sie und fragte laut: »Aber, Kind, fehlt dir etwas? was machst du nur für wunderliche Augen? Ich glaube gar, am liebsten wärst du mit Erik dort?«

Ruth fing mit feinem Ohr den nicht ganz liebreichen Ton auf und sah sie schüchtern an.

»Ich versuche es, dort zu sein!« sagte sie zum unaussprechlichen Erstaunen Klare-Bels.

Diese zog sich nach dem Abendthee bald in ihr kleines Gemach zurück, um sich zeitig zur Ruhe zu begeben, denn sie fühlte sich ein wenig leidend. Vielleicht griff die neue Behandlung sie an, die Erik seit kurzer Zeit mit ihr vornahm, und die er ihr auf viele Monate hinaus in Aussicht gestellt hatte. Er fing wirklich schon an, wieder neue Hoffnung zu schöpfen.

Gonne entfernte sich, nachdem sie ihre Frau sorgsam gebettet, und Klare-Bel lag in ihrem stillen Zimmer allein, umgeben von all den zierlichen und saubern Sächelchen, die sie bei sich aufzustellen liebte.

Sie lag und lächelte über sich selbst. War es nicht seit kurzem, als ob auch sie, ganz leise -- leise, heimlich, die neue Hoffnung hätschele? Ein klein wenig nur. Die Hoffnung, doch noch einmal wieder gesund zu werden, Erik entgegengehen zu können auf ihren zwei gesunden Füßen.

Es war ja gewiß nichts damit. Ein bloßer Wahn. Aber wenn er trog, dann würde Erik sie schon darüber hinwegtragen, wie über die vielen, vielen frühern Enttäuschungen auch. Denn das hatte er gethan, -- nicht gerade mit übermäßigem Bemitleiden und Schonen, aber mit seiner unaufhörlichen Gegenwart, mit seiner beständigen energischen Einwirkung auf sie. Und manchmal, da überkam sie ganz deutlich das Gefühl: es war gut so, denn er brauchte das; nur in diesem Bemühen überwand er seine eigenen Enttäuschungen. Seine starke Beeinflussung andrer schien es zu sein, durch die er immer wieder selbst zur alten Sicherheit zurückkehrte. So oft konnte sie es mit Verwunderung beobachten im täglichen Leben unter den Menschen seiner frühern Umgebung, wie belebend es auf ihn wirkte, daß sie von ihm Kraft und Belebung erwarteten. Das Alleinsein vertrug Erik wirklich schlecht.

Die Zeit rückte vor, und immer noch lag Klare-Bel wach und träumte mit offenen Augen. Durch das geöffnete Fenster strich weich und feucht die Luft, ganze Schwärme von kleinen Mücken mit sich tragend; von fernher verklang leise das Lied der letzten Landarbeiter, die von nächtlicher Arbeit heimkehrten. Mit hellen Sonnenaugen schaute die Nacht ins Zimmer herein.

Klare-Bel kamen ketzerische und sogar übermütige Gedanken, so daß sie über sich selbst erstaunen mußte. »Wer ist nun stark,« dachte sie, »wenn der Starke wieder der Schwachen bedarf?« Sie war sicherlich ein schwaches Wesen, froh, wenn Erik sie bei der Hand nehmen und führen wollte. Er aber, brauchte er denn nicht jemand um sich, den er führen konnte, um selber froh und des Weges sicher zu bleiben? Brauchte Erik also nicht sie, wie sie ihn?

Klare-Bel lächelte in der Einsamkeit der hellen Nacht, und inbrünstig streckte ihre Sehnsucht sich ihm entgegen. --

Wie sie es vorausgesehen, befand sich Erik erst Stunden später auf dem Heimweg. Er hatte mit vielen andern dem Freunde das Geleit bis zum Moskauer Bahnhof gegeben, und dann blieb man noch eine Weile zusammen, -- ein ganzer Haufen von Menschen, von Fremden und Bekannten, mit denen der Abend in angeregter Geselligkeit verbracht wurde. Erik ließ sich nicht mehr die Zeit, zu Hause vorzufahren, um sich umzukleiden; er erreichte eben noch den letzten Nachtzug und fuhr aufs Land hinaus.

Der lange Gang von der Station aus that ihm nach den verflossenen Stunden und Eindrücken wohl; die freie Nachtluft erfrischte ihn. Kein Lufthauch bewegte sich; am fast taglichten Himmel stand blaß und glanzlos der Vollmond; einzelne Wolken ballten sich aufeinander, und von Zeit zu Zeit sprühte ein feiner Regen nieder.

Als er am Hause ankam, das unter den regungslosen Bäumen in der Nachthelle dalag, wich langsam die noch erregte Stimmung einem Gefühl ruhiger Freude, wieder daheim und bei den Seinen zu sein. Bei ~den~ Seinen! Auch Ruth gehörte jetzt dazu. Gehörte ihm zu.

Er stieg leise die Stufen zur Terrasse hinauf und warf einen Blick auf die Giebelstube, wo sie jetzt schlief und träumte. Da, als er fast geräuschlos die Hausthür aufgeschlossen hatte, knarrte die schmale Holztreppe, die vom Flur nach oben führte, unter einem leichten Fuß. Völlig angekleidet, nur das Haar ein wenig wirr um den Kopf, erschien Ruth auf dem untersten Treppenabsatz.

»Aber, Ruth, was fällt dir ein? Wie konntest du aufbleiben? Schnell ins Bett!« sagte er.

Er schalt, doch klang es sehr herzlich. Empfand er doch ihr liebes Gesicht wie einen Willkommgruß.

»War es schön?« fragte sie entgegen und blickte ihn mit großen überwachen Augen an, »sollte ich denn dabei schlafen? Nein, das konnte ich nicht! denn ich war auch da, -- immer mit da. War es schön?«

Er faßte nach der sich ihm entgegenstreckenden Hand und hielt sie fest. Alle Eindrücke des Tages, alle Erinnerungen, die von ihnen aufgewühlt worden, verflogen; er hatte den ganzen Menschenstrom hinter sich gelassen und war nur noch ganz allein mit ihr.

Was bedeutete ihm alle Anregung, ja, was aller so ersehnte Beifall oder Erfolg, nach dem er im Leben gegeizt und gerungen, gegenüber dem zarten Lob, wie es aus Ruths kindlicher, gläubiger Hingebung an ihn redete? Wie schal und brutal erschien ihm daneben alles, was von einer Menge ausging und sich laut äußerte. Nur wessen Sinne zu stumpf geworden für so feinen Duft, der mochte nach schärfern Würzen suchen.

Dieser Gedanke flog Erik durch den Kopf und darüber vergaß er zu antworten.

Er sah gut aus im Gesellschaftsanzug, den weiten Mantel lose umgeworfen, regenbesprüht, und darüber das belebte Gesicht. Wie sie so einander gegenüberstanden in der schweigenden Nacht, während die ganze Welt um sie her im Schlummer lag, erschienen sie beide wie gesättigt mit Leben; und etwas Verwandtes schien aus beider Ausdruck zu sprechen, -- verwandt über Alter und Geschlecht hinaus, -- ein Lebenverlangendes, Lebenforderndes. Es war dasselbe, was Erik so verwandt berührt und ergriffen hatte, als er Ruth zuerst im Schulhof sah, mit dem Uebermut in den Augen und den erhobenen Armen.

Sie standen und schwiegen, und um sie her träumte die magische Helle, in der Abend und Morgen unmerklich ineinanderschmolzen.

»Hätte ich nicht fortgehen sollen, Ruth?« fragte er unwillkürlich und blickte sie mit einem Lächeln an.

»Doch! aber mich mitnehmen!« entgegnete sie, und im Klang ihrer Stimme verriet sich die ganze Sehnsucht und Selbstentrückung, in der sie den Tag über umhergegangen war. Erik verstand sie nicht ganz, er nahm die nachträgliche Bitte kindischer und tatsächlicher, als Ruth sie meinte, aber Blick, Ton und Haltung drückten es so kindlich aus, daß sie sich in seiner Abwesenheit wie verloren gefühlt hatte, daß eine tiefe Rührung über ihn kam.

Ihm schien, Ruth sah wie verzaubert aus, -- anders, lieblicher als sonst.

Im Hause blieb es ganz still, und beide sprachen mit gesenkter Stimme. Nur durch die offen gebliebene Hausthür zog es ganz leise wie ein geheimnisvolles Raunen und Rauschen, -- ein Flüstern, das draußen durch das niedrige Gebüsch ging, -- die erste Ankündigung des neuen Tages.

»Es ist Zeit!« sagte Erik aufschreckend, »lege dich schlafen. Gute Nacht! Guten Morgen. Liebling!«

Und mit einer raschen Bewegung zog er sie an sich, -- fest, so daß sie an seiner Brust lag, und küßte sie auf den Mund.

Als er sie ebenso rasch wieder losließ, hatte Ruth seine Hand ergriffen und drückte ihre warmen Lippen darauf.

Dann flog sie geschwind die schmalen Stufen zu ihrer Giebelstube hinauf.

Erik öffnete die Mittelthür im Flur, die in das Zimmer von Jonas führte. Er mußte hindurchgehen, um sein dahinter gelegenes Schlafzimmer zu erreichen. Dabei wachte Jonas auf.

»Na, Papa, war es schön?« fragte auch der und drehte sich schlaftrunken auf die andre Seite; »hat es denn auch Champagner gegeben?«

Damit schlief er weiter.

Erik stieß ein Fenster auf und blickte in die lichte Ferne hinaus. Ein farbloses, blasses, gleichmäßiges Grau breitete sich in der Stube aus, und der dämmernde Morgen fing an, sie mit herber Kälte zu erfüllen.

Das leise Raunen und Rauschen schlich nicht mehr flüsternd am Boden hin, es hatte sich höher erhoben. Es bewegte die Zweige der wilden Akazien, die dicht vor dem Fenster standen, und dann schwoll es machtvoll an, bis es in majestätischem Brausen die alten Wipfel durchklang, die vorhin lautlos gegen den hellen Nachthimmel starrten.

Wie ein Morgenchoral klang es, und -- ganz leise, -- versuchend, wie im Halbschlafe noch, fiel hie und da ein kleiner froher Vogellaut ein. Und bald darauf, gleich einem Aufjauchzen, ein lang gezogener unermüdlicher Buchfinkentriller.

Erik hatte sich zur Ruhe gelegt, aber mit wachen, lauschenden Sinnen nahm er das Nahen des Tages auf, und es kam ihm vor wie eine geeignete Begleitung zu seinen Gedanken, die noch an Ruth hingen. Denn auch über ihnen lag eine zarte und halbverhüllte Stimmung, eine Morgentraumstimmung, so schien ihm.

Noch nie hatte ihn die Empfindung so gepackt wie heute, daß sie ja unwiderruflich zu einander gehörten, daß sie im Grunde gleichgeartet, gleichen Wesens seien. Und nun erst meinte er ihre Bitte zu verstehen: »Mich mitnehmen!« Was er war, das wollte auch sie sein, denn nur in ihm erfaßte und ahnte sie sich selbst. Der gleiche Lebensdrang schlummerte stark und freudig in ihnen beiden. Nur daß in ihr aus unbewußtem, unberührtem Naturgrunde hervorbrach, was in ihm bewußter Entschluß, Verstand und Wille gewesen. Und daß in ihr mit reiner Flamme brannte, was in ihm die Berührung mit dem Leben mit Schlacken und Asche vermengt hatte.

Und über diesen unklaren Gedanken fing Erik an zu schwärmen.

Der erste Jubel der Vögel draußen legte sich, und der Morgenwind schwieg still. Wieder ragten die alten Bäume regungslos gegen den Himmel, durch dessen Blau zerrissene weiße Wolken schwammen. In einem breiten Goldstrom flutete das Sonnenlicht durch das Gemach.

Hinter Eriks geschlossenen Augenlidern malte es lächelnd rosige Farben. Im Sonnenschein war er eingeschlafen.

Er erwachte viel später als sonst und besann sich nicht gleich, weder auf den gestrigen Tag, noch auf die Nachtstunde. Irgend ein Traum, ein wunderbarer, von dessen Vorgängen er aber nichts mehr wußte, hielt ihn noch fest in Bann. Und offenbar aus diesem Traum heraus kam ihm zwingend die seltsame Frage: »Ist sie schön? Ich weiß es nicht; ich glaube eher: nein. Aber sie sieht aus wie -- Ruth. Es ist ja Ruth.«

Und ihm schien, es könne nur ~eine~ solche geben.

Er fühlte eine Mischung von Glück und schmerzlicher Beklommenheit.

Und blitzähnlich wurde er vollständig wach.

Wie ein Schicksal, groß und schwer, stand vor ihm die Erkenntnis seiner Liebe.

Noch nie hatte er über sein Gefühl für Ruth nachgedacht. Vielleicht, weil es überhaupt wenig seiner Natur entsprach, über sich nachzudenken. Vielleicht aber auch, weil dieses Gefühl einem leidenschaftlichen Interesse am Menschen, nicht am Weibe, entsprungen war.

Plötzlich war das alles anders geworden. --

Auf der Terrasse saßen sie schon lange und warteten am Frühstückstisch auf Erik, als er endlich zu ihnen heraustrat. Klare-Bel bemerkte augenblicklich etwas Verändertes, Verschlossenes in seinem Gesicht, und sie bewies es, indem sie keine Frage an ihn richtete und von Gleichgültigem zu reden begann.

Erik jedoch erzählte unaufgefordert manches vom Zusammensein mit dem Freunde. Die Frau war wirklich auch dabei gewesen; sie war eine Deutschrussin und besaß Verwandte bei Moskau.

Sie hatte Erik außerordentlich gut gefallen. Heiter, gütig, praktisch, -- ein kluger und reifer Mensch, sagte er von ihr.

Klare-Bel hörte nur mit halbem Ohre zu. Sie fühlte sich sonderbar beunruhigt und fand im stillen, daß Erik nach der gestrigen Zerstreuung reichlich überwacht und angegriffen aussähe.

Um so frischer und heller sah Ruth aus. »Wie angesteckt von der Morgensonne,« dachte Erik, während sein Seitenblick sie streifte. Dabei konnte er ihr ansehen, wie sie nur mit Mühe einen Witz darüber unterdrückte, daß er verschlafen habe. Sie hatte nicht verschlafen. Sie hatte den ganzen Frühmorgen im Garten umhergetollt.

Mit der gemeinsamen Arbeit wurde es heute nun nichts. Hastiger als sonst stand Erik auf, um zu gehen. Die Zeit drängte, und Jonas war schon fort.

Erik konnte es kaum erwarten, daß das Haus weit hinter ihm lag, und er wieder mit sich selbst allein blieb. Aber dennoch war ihm weder zum Träumen noch zum Grübeln zu Mute. Nur nach ~einem~ verlangte es ihn dringend und ungeduldig, als hinge das Leben davon ab: voll und klar ins Auge zu fassen, was seit wenigen Stunden wie sein Schicksal vor ihm stand. Nur nach ~einem~ verlangte ihn: davor stillzustehen und den Blick darauf ruhen zu lassen, fest und forschend, wie auf einem fremden Antlitz.

Darüber entschwand alles andre, was ihn hätte beschäftigen und beunruhigen können, völlig aus seinem Gesichtsfeld. An allem, was bisher sein Schicksal ausgemacht und zwingend sein Leben bestimmt hatte, an allen innern und äußern Verhältnissen, in denen er lebte, sah er vorbei, -- ganz gerade, ganz unverwandt auf den ~einen~ Punkt, ohne nach rechts oder links zu schauen. Für etwas andres blieb kein Blick, kein Raum, es blieb nur eine dunkle, trotzige Nebenempfindung: über ~Hindernisse~, und wären es Menschen, geht's hinweg. --

Ehe Erik sich mit Klare-Bel verlobte, hatte sie ihm einmal eine Photographie geschenkt, auf der sie sich im Kreise ihrer ganzen Familie befand. Er steckte das Bild in einen Rahmen und legte zwischen Rahmen und Glas ein Blatt Papier, in das er eine nur Bels Gestalt entsprechende Oeffnung ausgeschnitten hatte: so war er mit ihr allein. Ihre Sippe deckte er zu, weil sie ihm nicht gefiel.

Erik war es sich nur halb bewußt, daß er es jetzt ebenso machte: mit feiner eigenen Familie, mit den Menschen und Pflichten seiner täglichen Umgebung, ja, mit der gesamten Welt, die er in seinen Gedanken weglöschte, bis nichts übrig blieb als eine unermeßliche leere Weite, eine Welteinsamkeit, in der nur Ruths Bild vor ihm stand.

Sie und er, allein miteinander, und Auge in Auge.

Aber je länger er auf sie hinschaute, desto stiller wurde sein Blick. Was alle Hindernisse und Schranken in ihm wie außer ihm nicht an sein Bewußtsein heranbringen konnten, das ging von dem fröhlichen Kinderbilde selbst aus. Alles harte und leidenschaftliche Fordern in ihm wurde still.

Was liebte er denn an ihr, wenn nicht eben dieses Kindhafte, in dem noch, geheimnisvoll und verheißungsvoll, die ganze Fülle der Möglichkeiten ruhte, -- dieses Keimende, Werdende, Zukünftige, das noch auf lange hinaus der schützenden Hülle bedurfte, -- den zarten, kostbaren Stoff, nach dem seine Hand sich nur herrisch ausgestreckt, weil sie allein ihm die edelste Form geben wollte?

Ihm fiel das Gleichnis vom Gärtner und seinem Bäumchen ein, das er Ruth einmal erzählt hatte. Es enthielt eine Wahrheit, es enthielt seine Liebe. Unsäglich liebte er in ihr seine Gärtnerkunst und seine Gärtnerhoffnungen.

Je länger Erik sich aber so in das ihm vorschwebende Bild vertiefte, um so weniger klärte sich ihm sein eigenes Gefühl. Er sprach zu sich selbst nur noch mit geringer Ehrlichkeit. Unwiderstehlich erhob sich aus dem leidenschaftlichen Begehren der Hang zu idealisieren. Allmählich büßten in seiner Phantasie er wie Ruth viel von ihrer Wirklichkeitsfarbe ein, und immer höher ging der Schwung der Gedanken.

Während Erik glaubte, es sei der Erzieher und Menschengestalter in ihm, der in reiner Hingebung an einem Frauenbildnis meißele und dichte, damit es einst Wirklichkeit werde, schwelgte und berauschte sich der Liebende an Ruths unähnlichem Idealporträt. --

Ruth hatte inzwischen den Vormittag in einer Weise verbracht, die diesen hochfliegenden Vorstellungen nur wenig entsprach.

Anfangs überlegte sie ein Weilchen, ob sie die Absicht hege, ganz für sich allein fleißig zu sein. Nein, die hegte sie entschieden nicht. Am besten hätte es ihr gepaßt, jetzt Jonas da zu haben, aber der saß in der Schule und lernte, der Aermste. So entschloß sie sich denn, zu Gonne in die Küche hinunterzugehen. Denn lieber noch wollte sie mit den Händen thätig sein als mit den Gedanken, meinte sie, und irgendwie lebhaft sich bethätigen mußte sie durchaus. War ihr doch froh, so vogelfroh, so gar nicht zum Stillsitzen und zum »Nachdenken«. Und dann war es auch ganz unterhaltend, mit Gonnes Eimern am Brunnen zu plantschen.

Gonne litt es glücklicherweise gut, wenn Ruth ihr so unerbeten mitten in die Arbeit sprang. Da sie nichts von der hierzulande üblichen Devotion besaß, so betrachtete sie es als eine Auszeichnung für Ruth, daß sie sich deren Hilfe gefallen ließ. Und Ruth nahm es auch nicht anders, und zum entsprechenden Dank sang sie ihr mit ihrer weichen ungeschulten Stimme russische Volkslieder zur Arbeit, und Gonne hörte tiefernst zu.

Erik fand bei seiner Heimkehr Ruth mit aufgeschürztem Rock und zurückgestreiften Aermeln singend und seelenvergnügt am Brunnen. Bei diesem unerwarteten Anblick zerflatterte plötzlich das meiste von dem, was er sich zusammengesonnen und zurechtgelegt hatte; die verklärte Gestalt seiner Phantasie, um derentwillen er die wirkliche Ruth am tiefsten zu lieben glaubte, war wie versunken. Eine stürmische Zärtlichkeit erfüllte ihn, ein heißes Verlangen, sie an sich zu ziehen, die schlanken wasserübersprühten Arme unter seiner Hand zu fühlen, die lachenden Lippen zu küssen und das stets verwirrte Haar und den feinen von der Sonne schwach gebräunten Hals.

Im Begriff an der Terrasse vorüber zum Brunnen zu gehen, machte Erik plötzlich Halt, kehrte um und ging in sein Zimmer.

Dort, auf dem Schreibtisch, lagen noch, unordentlich, Ruths Hefte und Bücher umher, die heute morgen umsonst auf ihn gewartet hatten. Erik setzte sich davor nieder und beugte den Kopf auf seine Hände. Das Blut hämmerte ihm in den Schläfen, und er drückte die Zähne gegeneinander. -- -- --

Mußte Ruth fort?

Er zwang sich, den Gedanken zu Ende zu denken. Ihn überschlich eine Ermattung, eine bleischwere Müdigkeit, die alles klare Denken umschleierte.

Halb mechanisch blickte er über die Hefte hin, die aufgeschlagen dalagen; ohne zu lesen, folgte er den einzelnen Buchstaben, als enthielten sie eine erlösende Antwort. Es war eine rasche, in den Grundstrichen harte Schrift, deren Züge alle fest zusammenhingen. Noch keine ausgeschriebenen Rundungen, aber auch kein überflüssiger Schnörkel.

Ihm fiel wie von ungefähr auf: in Ruths Handschrift lag im Grunde eine fremde Ruth. Nichts von ihrer Phantasie, -- ihrem Ueberströmen. Etwas merkwürdig Logisches.

Seine Blicke und Gedanken blieben darauf haften.

Lag nicht vielleicht auch in ihr selbst noch eine ihm fremde Ruth? Die noch nicht erwacht war, die er noch nicht kannte?

Da lachten ihre Augen durch das Fenster. Ruths Kopf erschien zwischen den krausen Ranken und Blättern des wilden Hopfens, der am Fensterkreuz emporkletterte.

»Soll ich arbeiten?« fragte sie.

»Nein. Wir wollen auch Ferien machen. Wenigstens für heute,« sagte er und stand auf, »weißt du, was es für eine Ueberraschung gab, -- in der letzten Stunde vor den Ferien, in der Mädchenschule? Sie erhoben sich alle und trugen feierlich eine Bitte vor. Was es war, ließ sich nicht leicht herausbringen. Sie wußten es selbst nicht genau. Sie wollten dasselbe, was du gewollt hast, sagten sie. Sie wüßten es nur nicht zu bewerkstelligen.«

Von Ruth kam nur ein Gelächter. Er hatte es schon in der Schule um sich zu hören geglaubt. Ganz deutlich empfand er aus dem unerwarteten »Massenerfolg« den übermütigen Einfluß einer einzelnen heraus. Aber gerade dies hatte ihn heute aus seiner zerstreuten Gleichgültigkeit gerissen, ihn mit Wärme und Freude erfüllt. Aus dem Bilde der ganzen Klasse, aus der Gesamtphysiognomie all dieser braunen und blonden Mädchenköpfe, schaute ihm, wie aus einem Vexierspiegel, Ruths Gesicht entgegen: mit einem Schalkslächeln um den Mund, aber auch mit unbegrenzter Hingebung in den Augen. Ganz so, wie sie jetzt eben zwischen den Hopfenranken dastand.

»Aber nun wird Ernst damit gemacht,« bemerkte er und lehnte sich ans Fenster; »im Herbst, wenn alle wieder zusammenkommen. Vielleicht in Form von allgemeinen Kursen bei mir zu Hause. Vielleicht bei Beteiligung Erwachsener. Ich weiß noch nicht, wie.«

Sie sah ihn voll Interesse an.

»Das ist gut!« sagte sie eifrig und nickte, »je mehr, desto besser. Aber alle werden nicht kommen dürfen, und manche werden bald wieder fortbleiben. Daß die Braut da ist, nimmt vielen die Lust zu so etwas fort.«

»Die Braut?«

»Ja. Denn da denken sie nun, so schön könnten sie es jetzt bald alle kriegen. Und dann hat ja all das andre keinen rechten Zweck mehr, meinen sie. Denn sie finden: Braut sein, das sei doch das Allerhöchste. Darüber haben wir uns vorgestern im Schulhof unterhalten.«

Er blickte auf sie.

»So. Und was hast denn du dazu gemeint? Hast du auch gefunden, daß es das Allerhöchste sei, und daß dann all das andre keinen rechten Zweck mehr hat?«

»Ich? Das kann ich ja gar nicht wissen. Wie soll ich wissen, wie es dann ist? Aber ich brauche es doch auch gar nicht zu wissen. Denn ich kann niemals Braut werden,« sagte Ruth.

Das Wort erschütterte ihn in seiner nervösen Erregung. Er war so betroffen, daß er nicht gleich antworten konnte. Dann entgegnete er: »Wie kommst du auf diesen wunderlichen Gedanken? Wo hast du diesen Einfall her? Du bist ein Kind, das nichts davon voraussehen kann, wie sein zukünftiges Leben sich gestalten mag. Und deine Phantasie soll nicht damit spielen. Du sollst nicht damit spielen!« wiederholte er mit plötzlichem, unmotiviertem Zorn. »Sage mir, wie du darauf gekommen bist.«

»Es ist von selbst gekommen,« sagte sie einfach, »ich habe nicht damit gespielt. Es ist gekommen, weil ich wußte: um Braut zu werden, muß man einen lieb haben. Und das kann ich ja nicht mehr. So lieb kann ich in der ganzen Welt nie mehr jemand haben.«

»~Wie~ lieb, Ruth?«

Seine Stimme klang gedämpft und heiser.

Sie sah ihn an mit ihrem offenen naiven Kinderblick. Nie noch, meinte er, eine solche Unschuld und Treuherzigkeit in einem Menschenblick gesehen zu haben.

»So lieb wie Sie,« sagte Ruth.

Erik machte eine kurze Bewegung und, niederblickend, schob er die Hopfenranken zur Seite, die sich überall festnestelten und anklebten. Die linke Hand, die in der Seitentasche seiner Joppe lag, ballte sich zur Faust.

Ruth betrachtete ihn unverwandt, aber sie verstand nicht den Ausdruck, der über sein Gesicht ging.

Da, wie Erik, fast furchtsam, aufschaute und die fragenden Augen vor sich sah, durchzitterte es ihn. Ihm kam es vor, wie wenn dieser eine Blick und Augenblick über ihn entscheide.

Er beugte sich etwas vor, ergriff Ruths Hände und bedeckte damit seine Augen.

»Weißt du, Mädel,« sagte er halblaut, »wenn du groß bist, -- denn jetzt bist du doch nur erst ein kleines Mädel, -- aber wenn du längst eigene und reife Vorstellungen gewonnen hast über alle diese Dinge, und viele andre noch, -- dann -- ~dann~ sollst du noch einmal zu mir kommen und mir sagen können: daß du mich lieb behalten hast. Und daß du von mir -- ~von mir~ dein Bestes hast. Dein Eigenleben und deine Entwickelung. Deinen Glauben an deinen Selbstwert und den Glauben an den Wert der Menschen. Wer du dann bist, Ruth, das wissen wir beide nicht; wer ich dann bin, das weiß ich ja wohl: ein alter Mann. Aber ein alter Mann, der dafür gelebt hat, daß du, Mädel, ihm bleiben darfst, was du ihm heute bist: sein Stolz, sein Werk, sein Kind und seine höchste Hoffnung.«

Und er ließ ihre Hände los und verließ das Zimmer.

Ruth stand noch draußen am Fenster. Sie hatte die Arme aufgestützt und blickte ihm regungslos mit ernstem Gesichte nach.

An einem der nächsten Tage, um die Mittagsstunde, füllte eine bunte Menschenmenge den großen Mädchenschulsaal. Eltern und Angehörige der Kinder, eine Flut von Neugierigen aus den obern Gesellschaftsschichten und viele, die Erik reden hören wollten, von dem die Mädchen zu Hause so viel erzählten.

Er stand auf der Tribüne im Hintergrunde des Saales und sprach zu ihnen und ihren Kindern; er erwähnte den Vorschlag, den seine Klasse ihm gemacht, die Gemeinsamkeit des Lebens und Arbeitens über die Schule hinaus zu erstrecken, und knüpfte daran seinen Lieblingsgedanken von der Notwendigkeit einer reichern Weiterentwickelung für die Frau, als die Gegenwart sie ihr außerhalb der Schuljahre gewähre. Ueber die Möglichkeit, eine lebensvollere, geisteskräftigere Zukunft heraufzuführen, sprach er ihnen, und über die Zukunft der Frau, die, erst geahnt und nur halbenthüllt, noch vor ihr liege, von der sie aber Besitz ergreifen könne in allem, was ihr Wesen der innern Entfaltung und Vollendung näher bringe.

Und während er sprach, dachte er an Ruth, der er nicht erlaubt hatte, mitzukommen; denn im Grunde war sie es ja, von der er redete, zu der er redete. Sie war es ja, die in ihm die Lust wiedererweckt hatte, zu den Menschen zu reden, und die Menschen für ihn suchte, wie man für einen Armen Brot sucht, damit er seinen Hunger stille. Und was er seinen Menschen gab, entnahm er ihr: denn das Höchste, was er von ihr erhoffte, das Schönste, was er sich in ihr träumte, legte er seinem Zukunftsbild unter, und dann erhob und verklärte er es zu allgemeinen Formen.

Es war, wie wenn er eine überlebensgroße Gestalt vor den gebannten Menschenaugen aufrichtete, in der durch diese Größe die individuellen Züge unerkennbar wurden. Zu groß sicherlich, für das wirkliche Leben, aber von einer Fülle und Wärme der Farben, die unwillkürlich mit fortriß und sich dem weiblichen Teil unter den Zuhörern gewaltig einprägte.

So stand Erik und hielt eine Art von Selbstverteidigung seiner Liebe, und die tiefe Bewegung, die in ihm war, verlieh einem jeden seiner Worte eine eigentümliche Wucht.

Unter der Menge im Zuschauerraum befand sich auch Warwara, wie sie es ihm vorhergesagt. Sie blickte voll Interesse auf ihn. Ihr schien, als sähe sie vor ihren Augen entfesselt und entfaltet, was sie, mit ihrem feinen Instinkt, immer schon dunkel und undeutlich geahnt, wenn sie mit Erik zusammen gewesen: daß er Gewalt über Menschenleben besaß, und daß er in Hunger und Sehnsucht nach ihnen lebte. Es war also das, was sie zu gleicher Zeit so seltsam an ihm anzog und von ihm abstieß, -- das, was sie koketter erscheinen ließ, als sie war. Ihr fiel die Scene in seiner Stadtwohnung ein. Ja, ein Heiliger war Erik wohl sicher nicht. Aber selbst damals hatte sie mit Schrecken empfunden, wie suchend und sehnend und ungeduldig er aus das Innerste ging. Auf das, worin sie ihn enttäuscht hätte. Und das ließ ihre Eitelkeit nicht zu.

Als sie damals aus seiner Stadtwohnung nach Hause fuhr, hatte sich ihr fortwährend ein ganz abscheulicher Vergleich aufgedrängt. Sie konnte denselben nicht verscheuchen. Immer sah sie ein Weib vor sich, das falsche Brüste angelegt hat und sich deshalb vor der Berührung des Mannes, den ihre Gestalt fesselt, hüten muß. Hatte ihre Koketterie nicht ganz ähnliche Gründe? Sie fürchtete die geistige und seelische Entblößung. Und die Arbeit an sich selbst.

Es war aber wirklich ein abscheulicher Vergleich. Und zum größten Erstaunen ihrer Nachbarin errötete Warwara mitten im Vortrag.

Nach dem Schluß desselben, im Treppenhause, wo Warwara beiseite trat, um nicht in die hinausdrängende Menge zu geraten, bemerkte Erik sie und kam auf sie zu. Seine Augen leuchteten so. Warwara war blaß.

»Nun?« fragte er lächelnd und ganz in seinem alten, leichten Ton ihr gegenüber, »fand der ›Toast‹ Gnade vor ihren Augen? Vielleicht war es wirklich einer.«

»Wenn es einer war, so könnte ich wohl auf ~die~ eifersüchtig -- nein, aber neidisch sein, deren Wohl Sie da ausgebracht haben,« versetzte sie, ebenfalls in ihrem gewöhnlichen Scherzton, aber ihr Gesicht blieb ernst; »~unser~ Wohl ist's nicht. Ich begreife jetzt, daß Sie anderswohin gehören wollen, als unter uns Gesellschaftsgelichter.«

»Aber, Warwara Michailowna!« sagte er, von ihrem Ausdruck frappiert, »warum nehmen Sie sich nicht aus?«

Sie schüttelte den Kopf.

»Aus Selbsterkenntnis. Ich hab' Sie heut verloren,« entgegnete sie und gab ihm die Hand, »also adieu, -- nicht nur für heute. Ich verzichte auf Sie. Ich entlasse Sie. -- Aber nun hören Sie: es ist doch der Schulrock, und nicht der Gesellschaftsrock, der Ihnen am besten steht.«

Er sah ihr nach, wie sie langsam die breite Treppe hinunterstieg. Aber als sie seinen Augen entschwunden war, vergaß er auch schon wieder, was ihm, durch den Scherz hindurch, heute an ihrem Wesen so aufgefallen war.

Und sein Blick glitt von ihr fort über die andern hin, die ihr folgten, über jung und alt, und vertiefte sich in die Mienen der einzelnen mit dem Interesse, das der wechselnde Ausdruck in den verschiedenen Menschengesichtern stets in ihm hervorrief.

Ja, nun begannen die Ferien, und die langen, nicht enden wollenden Sonnentage. Da würden seine Gedanken erst recht hierher wandern, in die Schule. Einen andern Wirkungskreis gab es wohl nie mehr für ihn, -- einen breitern. Er wollte auch keinen in diesem Augenblick. Sein Ehrgeiz schwieg still. Zu Kindern reden lernen wollte er, und die Großen zu Kindern machen, bis auch sie empfänglich wurden, gleich denen, die da noch wachsen.

Mit diesen Gedanken verließ Erik das Schulgebäude.

Er war ungeduldig, heimzukommen: er sah eine Bank im Garten, hinten am kleinen Gehölz, unter den überhängenden Birkenzweigen, und Ruth saß darauf, und lauschte, während er ihr von allem erzählte, was »er sich ausgedacht«. Zusammen wollten sie's sich ja ausdenken, hatte er ihr versprochen.

Daheim sein bedeutete jetzt nicht mehr bloß die Stille und das Behagen, aus denen seine unbefriedigte Thatkraft ruhelos und vergeblich in die Weite gestrebt hatte. Daheim umfing ihn gerade seine liebste Arbeit und Aufgabe, -- daheim fiel jetzt Innen und Außen, Ruhen und Wirken, Träumen und Schaffen in ~eins~ zusammen. In Ruth war etwas, das machte sein ganzes Wesen produktiv, erregte und vertiefte alle seine Kräfte, so daß leise von ihnen abglitt, was dem äußern Ehrgeiz angehört.

Als Erik die Gartenpforte öffnete, sah er auf dem Rasen, zwischen den Bäumen, ums Gehölz herum, eine wilde Jagd. Er sah Ruth, Jonas -- und noch einen. Einen mittelgroßen, etwas untersetzten Mann mit kurzem dunkeln Vollbart und Brille. Der jagte sich mit Ruth, und haschte vergeblich nach ihr. Seine Stimme klang scherzend und lachend herüber.

Es war Bernhard Römer.

Nun wurde er Eriks ansichtig und kam heran.

»Auf einen Tag und eine Nacht, wenn's recht ist!« rief er, ein wenig außer Atem, und fuhr sich mit dem Taschentuch über das kurzgeschorene dichte braune Haar; »-- und die Ruth nehme ich gleich mit fort, -- das heißt, wenn ich sie hasche. Dann soll ich sie kriegen, haben wir ausgemacht,« fügte er hinzu, während sie sich die Hände schüttelten, »das ist ja ein reizendes Ding. Sieht aber noch aus wie ein Kind. Vierzehnjährig.«

»Sie ist zart,« sagte Erik und stieg mit ihm die Terrasse hinauf.

»Zart? Muskulatur wie eine stählerne Feder. -- Es ist ungerecht, daß du sie hast. Wir brauchen ein Hauskind. Ihr habt ja den Jungen.«

»Bist du schon so schnell zurückgereist? Und deine Frau?« fragte Erik, ihn unterbrechend, und bot ihm einen Stuhl neben Klare-Bel, die auf der Terrasse lag und lächelnd dem lustigen Treiben zugesehen hatte.

»Ich mußte zurück. Und meine Frau? Ja, die wollte noch nicht zurück. Die Frauen sind heutzutage entsetzlich selbständig. Sei froh, daß Bel dir nicht fortlaufen kann. -- Meine Frau, die reist also herum und besichtigt Suppenanstalten.«

»Suppenanstalten?«

»Na ja. Und besucht auch noch den verrückten Grafen in Jasnaja Poljana. Für so etwas interessiert sie sich nun einmal. Von Rechts wegen sollte ich wohl meine hochwohllöbliche Professur aufgeben und ein russischer Bauer werden, der das Feld pflügt. Aber ein so edler Mann und Ehemann bin ich nun doch nicht.«

»Ich finde: sehr,« bemerkte Klare-Bel staunend, »da Sie Ihrer Frau alles das erlauben.«

»Erlauben?« Bernhard Römer lachte herzlich und setzte sich zu ihr. »Meine liebe gnädige Frau, ich will es Ihnen nur gestehen: ich habe gar nichts zu erlauben. Wissen Sie warum? Ich bewundere nämlich ein wenig meine unartige Frau. Bei uns zu Hause hat sie auch so etwas wie Suppenanstalten eingerichtet. Natürlich nur sehr im kleinen, -- sagen wir lieber: im winzigen. -- Aber nun will ich dir etwas sagen, mein lieber Erik: wir haben einst so im größten, im allergrößten, herrliche Pläne gemacht von Vervollkommnung des Lebens und der Menschen, -- aber meine Frau, die führt sie im kleinwinzigen aus. Nur sie. Das ist die Art, wie sie sich meine

Pläne zu Herzen genommen hat, nachdem ich wohlbestallter und -- wohlbeengter Professor geworden bin. Daß sie nur so wenig kann, hält sie von nichts zurück. Das Leben ist Frauenhand und Frauenarbeit -- mutige. Wir sind Stümper dagegen.«

»Deine Frau ist sehr außergewöhnlich,« bemerkte Erik, »ich bin froh, sie kennen gelernt zu haben. Aber entbehrst du sie denn nicht jetzt zu sehr im Hause? Wie lange bleibt sie noch fort?«

»Bis zu den Ferien. Den deutschen Universitätsferien. Entbehren? Ja, -- doch in der Arbeitszeit, da behelfe ich mich schon mit der Wirtschafterin und schlecht bereitetem Kaffee. Denke mir halt dabei: 's ist Arbeitzeit, Wochentag. Aber in den Ferien, -- ~meinen Ferien~, -- da muß ich Sonntag haben. Da muß ich -- muß ich meine Frau um mich haben.«

Klare-Bel sah ihn erfreut an. Sie freute sich über seine herzlichen Worte. Freute sich, ihn wiederzusehen. Kaum konnte sie's glauben, daß er selbst es war: der bartlose Jüngling mit dem braunen Lockenkopf, -- sanfter als Erik, stiller, ein schwärmerischer Utopist mit einem kleinen Stich ins Phlegma und in den deutschen Michel.

Und während Erik ins Haus ging, vertieften sie sich von neuem in die alten Erinnerungen, wie sie es schon heute morgen miteinander gethan. Und beide wurden warm beim Heraufbeschwören der Jugend und empfanden beide mit uneingestandener Wehmut, daß die Jugend Vergangenheit war.

Erik störte sie nicht. Er stand in seinem Zimmer. In erregter Stimmung.

Ruth mit Römer, -- nicht mit ihm: er konnte das Bild nicht loswerden.

Des Freundes Leben daheim stand ihm klar vor Augen. Ein seltenes Heim, -- das seltenste: eine vollglückliche Ehe. Neben dem Mann die gleichaltrige Frau, in der, wie ein Stückchen seiner Jugend, das nicht sterben wollte, die Frische weiterlebte, die ihn vor dem Vertrocknen in Professorenweisheit und zufriedener Sattheit bewahrte. Daher seine ewigfrische Liebe zu ihr, daher für alles, was sie plante, das offene Herz und die offene Hand.

Dort würde Ruth haben, was ihr not that: in körperlicher, geistiger, praktischer Beziehung. Und indem sie ~ihn~ verlor, eine mütterliche Freundin gewinnen, der er sie blind anvertrauen konnte.

Irgend etwas raunte Erik zu: »Gib sie hin. Dort wäre die selbstlosere Liebe. Schütze sie vor dir selbst.«

Seine Augen verfinsterten sich, und um seinen Mund erschien eine harte Linie.

Nun ja, er gestand es sich ein: daß er selbstlos Ruth dienen wollte, das war nur, um sie zu behalten. Er hatte außer ihr nichts zu verlieren, was ihn ganz erfüllte. Er kämpfte um das Schönste und um das Letzte, -- das fühlte er. Und um das Höchste: um sich selbst.

Man sagt oft: erst der Zusammenbruch des ganzen persönlichen Glückes führe manchen zur wahren, menschlichen Größe, lehre ihn erst, wahrhaft thatkräftig den andern zu dienen, auf andre zu wirken.

Gewiß gab es solche milden Menschen in der Welt. Aber galt es von ihm? Konnte er je zu ihnen gehören? Laut schrie es in ihm: Nein! Nein!

Seine Kraft und sein Glücksverlangen wollten sich nicht trennen. Miteinander verwachsen waren sie von der Wurzel an. Glück brauchte er, um Mensch zu bleiben. Viel Glück, um gut zu bleiben. Er mußte es zu sich zwingen in irgend einer Form, -- und um jeden Preis.

Um jeden? Gab es nichts, was ihn veranlassen konnte, einst selbst die Axt an die Wurzel zu legen?

Bels Glück? Nein! Aber Ruths Glück.

Er versuchte, gewaltsam, den Gedanken fortzustoßen. Er setzte sich an den Schreibtisch und versuchte, ein paar Aufzeichnungen auszuführen, die er sich unterwegs für seine Winterpläne entworfen. Er versuchte, sich dabei die Mienen einzelner zu vergegenwärtigen, die er an der Treppe, im Vorbeigehen, studiert, und in denen er den Ausdruck der Freude und der Anregung gelesen hatte.

Aber die Gedanken verschwammen, und die Gesichter verblaßten. Er sah nur noch ein Chaos fremder, gleichgültiger Physiognomien, -- ohne Ausdruck, ohne Freude, ohne Blick.

Unschöne, an denen sein Auge vorüberglitt, -- hübsche, aus denen es teilnahmslos haften blieb.

IV.

Kurz und glühend, wie immer, war der russische Hochsommer vorübergeflogen, und früh, mitten im August, nistete sich leise der Herbst im Garten ein und verlöschte mit seinen langen dunkeln Abenden die Sonne. Der Rasen sah fahl und versengt aus, und längs den Kieswegen sammelten sich die ersten dürren Blätter.

Gerade da, wo Klare-Bel in ihrem Stuhl am Rande des kleinen Gehölzes lag, konnte sie an den Birkenzweigen über sich in einen breiten goldgelben Fleck hineinschauen, der täglich ein wenig zunahm. Und von Zeit zu Zeit sank eines der entfärbten Blätter, drehte sich in der Luft ein paarmal herum und flatterte zu ihr nieder.

Gleich daneben stand ein Tisch, roh aus ungeschälten Baumästen gezimmert, und zwei Bänke mit Rückenlehnen aus einem groben Flechtwerk von Weidenzweigen. Da saßen Erik und Ruth schon den halben Tag und arbeiteten.

Klare-Bel konnte nicht begreifen, wie sie das nur so ununterbrochen aushielten; manchmal schienen es ihr allerdings nur Unterhaltungen und Gespräche zu sein, die sie führten, aber sie wußte, wie ernst sie es damit nahmen, und daß Erik mitunter die Nacht aufblieb, um seinen Unterricht vorzubereiten.

Gern lag sie so und lauschte darauf; nicht auf die Worte, aber auf die Stimmen. Denn darüber täuschte sie sich nicht: nur in solchen Stunden noch klang Eriks Stimme gerade so froh wie früher. Und da war es wirklich gut, daß er sein Zimmer jetzt förmlich mied und mit Ruth immer in ihrer Nähe saß, wo sie ihn hören konnte.

Oft dachte sie dabei mit heimlichen Sorgen und Zweifeln an den ersten Tag im Juni zurück, den Erik mit Bernhard Römer und dessen Frau in der Stadt verbracht hatte. Seit dem darauffolgenden Morgen blieb er verändert. Und mit diesem Tage mußte es zusammenhängen. Aber den wahren Grund suchte sie in der fernsten Vergangenheit: namentlich seitdem sie den gemeinsamen Jugendfreund selbst wiedergesehen.

Denn seitdem begriff sie ganz gut, daß Erik vielleicht noch im stillen den alten Erinnerungen nachgehen mochte. Kehrten doch sogar ihre eigenen Gedanken häufiger als je dorthin zurück, wohin es keine Rückkehr gibt.

Die Jugend ersteht nicht wieder auf.

Wenn es doch eine Freude gäbe, -- dachte sie ganz heimlich bei sich, -- eine große, gewaltige Freude, die sie einmal über Eriks Leben bringen könnte, so daß er alles darüber vergäße! Aber sie besaß nichts, -- sie hatte immer nur so dagelegen, mit leeren Händen, und Opfer gekostet.

Vor wenigen Tagen brachte Erik unerwartet den Professor heraus, den er manchmal bei ihrer Behandlung hinzuzog. Sie war auf ihr Bett gelegt worden, und dann hatte Erik die in Angst und Schmerz Zitternde ganz fest in seinen Armen gehalten, bis qualvolle Minuten überstanden waren. Er selbst war ganz blaß. Aber der Professor wollte wiederkommen.

»Muß es sein, Erik?« fragte sie zagend.

»Es muß sein. Eine Aenderung ist da,« antwortete er ausweichend.

Aenderung! vielleicht Genesung!

Ja, nur ~eine~ große, gewaltige Freude konnte es noch geben: wenn sie selbst auferstand von ihrem Lager und zu ihm trat aus eigenen Füßen, -- da mußte er wohl wieder froh werden.

Und sehnsüchtig schaute Klare-Bel in die durchsonnten goldgrünen Zweige, von denen sich langsam die Blätter lösten. Und ihre Gedanken verträumten sich.

Als die Strahlen der Nachmittagssonne schräger fielen, und die Schatten der Bäume anfingen, sich zu dehnen und zu strecken, verstummten die beiden am Tisch, und Ruth stand auf.

Da erschien Klare-Bel jedesmal von neuem ganz eigentümlich bei diesem Unterricht, daß immer Ruth es war, die seinen Schluß angeben sollte. Erik wollte es so; nur diese selbst konnte genau wissen, wann ihre volle Frische und Empfänglichkeit nachließ. Er seinerseits konnte nur seine ganze und ungeteilte Kraft in das hineinlegen, was er ihr gab, -- und das that er. Er sammelte alle

Kräfte des Willens und des Geistes und konzentrierte sie auf einen einzigen Punkt: er hielt Ruth wie ein Fürstenkind, das man nur mit dem Auserlesensten beschenkt.

Er blickte sie an, wie sie, sonnengebräunt und mit vornübergewehtem Haar, neben ihm stand, in einer richtigen russischen Bauernbluse von grobem, ungebleichtem Leinen, mit roter Stickerei auf den Achselstücken und Oberärmeln, -- fast wie ein Kind aus dem Volk. Aber sein Fürstenkind war sie doch.

Er hatte ein Heft herangezogen, ohne Absicht es durchzusehen; nur mechanisch glitten seine Augen über die Zeilen hin. Doch Ruth blieb neben ihm stehen, und nun beugte sie sich über ihn, um hineinzublicken. Von Sekunde zu Sekunde wurde Erik nervöser. Und plötzlich, wegen eines geringfügigen Versehens, das er fand, herrschte er sie so heftig an, daß Klare-Bel erschrocken aufsah.

Ruth zog Schultern und Augbrauen hoch und schüttelte entrüstet den Kopf.

»Es ist nicht zu glauben. Wie kann man nur so kopflos sein, -- nicht wahr? Geradezu verdummt muß man schon dazu sein!« setzte sie mit unverhohlener Selbstverachtung seine Vorwürfe fort.

Erik war verblüfft und mußte über sie lachen.

Aber es berührte ihn wunderlich. Noch vor ein paar Monaten hätte etwas derartiges sie scheu gemacht, -- sie ~ver~scheucht. Jetzt weinte sie nicht mehr darüber, daß er sie ein dummes Kind nannte. Sie lachte. Lachte sich aus. -- Ihre Augen sahen ihn so spottend an. Wen verspottete sie eigentlich? Sich selbst, -- daran war kein Zweifel. Sich selbst nahm sie als einen fremden Gegenstand, den sie nur noch von Erik aus beurteilte; sie empfand, dachte und handelte nur noch wie aus seinem Wesen heraus.

Was war diese Selbstentrückung, dieses Uebermaß von Selbstvergessen im Grunde? war das Liebe? war es das, worauf er, halbbewußt und wider seinen Willen, -- wartete?

Klare-Bel hatte mitgelacht.

»Es wird dir noch sonderbar vorkommen,« sagte sie, »wenn du mit dem Herbst so viele Lerngenossen bei Erik bekommst. Wenn du mit ihnen alles teilen mußt. Wirst du nicht eifersüchtig sein, wenn nun eines von den Mädchen mehr kann als du?«

»Warum nicht?« fragte Ruth, und der Schalk ging durch ihre Augen, »dann wollen wir die eine lieber haben als mich. Wir haben Raum für viele da. Je mehr es sind, desto besser.«

Erik blickte auf. Am Ende würde sie wirklich eine dritte im Bunde mit Begeisterung empfangen? Aber wenn sie so spitzbübisch aussah, konnte niemand wissen, was sie bei sich dachte.

Er erhob sich und schob den Stuhl seiner Frau dem Hause zu, um sie vor Sonnenuntergang hereinzutragen. Jonas kam ihnen entgegen; den ganzen Nachmittag hatte er sich draußen auf den gemähten Wiesen herumgetrieben, aber immer paßte er den Augenblick richtig ab, wo er Ruth in Beschlag nehmen konnte.

Als Erik wieder aus dem Hause trat, sah er Ruth mit Jonas unter den Birken auf und ab gehen. Sie hielten sich lose umschlungen und stießen sich gegenseitig an den grasbewachsenen Wegrand, wo der Frühherbst das welke Laub angehäuft hatte. Es machte ihnen offenbar lebhaftes Vergnügen, mit den Füßen durch die Blätter hindurchzuraschelnd.

Jonas hatte Ruths Hand gefaßt, die auf seiner Schulter lag, und von Zeit zu Zeit neigte er den Kopf seitwärts und fuhr mit ihrer Hand liebkosend über seine eigene Wange.

»Jonas!« rief Erik den Knaben laut an.

Der schrak auf bei dem Ton.

»Was soll ich?« fragte er und kam betreten näher.

»An deine Ferienarbeiten sollst du!« sagte Erik, und schämte sich vor sich selbst.

Ruth folgte Jonas ins Haus.

Erik war im Garten stehen geblieben und sah den beiden nach.

Da war es wieder, -- dies Kindhafte, Kindische, dieses Unausgewachsene und sonderbar Unreife, über das er in Ruths Wesen nicht hinwegkam. Es nahm nicht ab, es nahm zu, -- es steckte ganz tief irgendwo, im Kerne ihrer Natur. Geistig hatte sie sich rasch und stark entwickelt, wie junges Laub in warmem Mairegen. Aber es war, als ob nun erst auch alle kindlichen Elemente sich entwickelten und zu immer vollerer Auslebung drängten, -- und daneben andere, beinahe männliche, die er in ihr bis dahin nur geahnt. So schnell gewöhnte sie sich daran, ihre Gedanken zu logischer Schärfe zu formen und ihnen eine energische Richtung auf das Erkennen zu geben, als habe sie nie in der Phantastik der Träume gelebt. Sichtlich hatte das Unentwirrbare, Unklare und Wildschweifende ihres Denkens nur mit den phantastischen Stoffen selbst zusammengehangen und fiel mit diesen von ihr ab.

Erik ging langsam in das Haus zurück, wo Jonas im Wohnzimmer mit resignierter Miene über seinen Büchern saß und zu lernen schien; aber im stillen grübelte er darüber nach, wie er Ruth dem Vater am besten abspenstig machen könnte, um sie mehr für sich zu haben. Morgen war ein Sonntag, da konnte man viel unternehmen; in diesen Ferienmonaten wurde schon früh gegessen, und so bekam man einen reichlich langen Nachmittag und Abend heraus. Aber Jonas fand es ungerecht, daß auf sechs Wochentage nur ein Sonntag fiel, und daß der Vater sich gerade die Wochentage genommen hatte.

Ruth saß nicht mit im Wohnzimmer. Sie mußte in ihre kleine Giebelstube hinauf gegangen sein.

Erik trat wieder in den Flur zurück und horchte, ob sich oben nichts rege.

Und dann stand er auch schon gleich darauf am Fuß der schmalen Holztreppe.

Wie ein Dieb erschien er sich selbst, als er da, in der Halbdämmerung, auf dem untersten Treppenabsatz zögerte.

Nur langsam nahm er die ersten Stufen, dann rasch die nächsten.

Wie lange, lange war er nicht mit Ruth allein gewesen, -- ganz allein. -- --

Oben klopfte er kurz und laut an. Ruth antwortete mit heller Stimme. Sie stand vor dem geöffneten Wandschrank, in dem sich ihre Sachen befanden, und kramte darin.

Außer einem Tisch und Stuhl am Fenster enthielt das kleine Gemach nicht viel mehr als am ersten Tage. Aber das Fensterbrett war mit Blumen gefüllt, mit gewöhnlichen Sommerblumen, wie die Straßenhändler sie auf einem Kopfbrett vorübertrugen, und darunter standen, am Boden, Töpfe mit Ablegern aus dem Garten. Und die Tapetenwand war bedeckt mit Bleistiftzeichnungen, die einen breiten Tintenrand als Rahmen empfangen hatten. Sie rührten alle von Jonas Hand her und stellten alle irgend einen Winkel des Gartens oder des Hauses dar.

Erik sah auf den Tisch nieder, auf dem Nähzeug und Papiere unordentlich durcheinander lagen.

Es fiel Ruth nicht ein, zu fragen, weshalb er heraufgekommen sei, aber in der leichten Verlegenheit, die er selbst empfand, suchte er nach einem Wort und zog eines der Papiere unter dem Nähzeug hervor.

»Schreibst du hier Verse?« fragte er überrascht.

Sie wurde dunkelrot.

»Nicht mehr so oft,« antwortete sie fast bestürzt, »und ich will ja auch gar nicht! Aber manchmal, wenn -- manchmal muß ich es noch thun.«

»So Verborgenes thun. Verborgen vor mir. Und ich habe geglaubt, daß kein Gedanke unausgesprochen, den ich nicht kenne, durch deinen Kopf geht.«

Sie machte ein so schüchternes Gesicht wie in alten Zeiten.

»Nicht verborgen,« sagte sie leise, »es sind nur eben keine Gedanken. Und aussprechen kann man sie auch nicht. Und die kommen nun und drängen sich, und dann muß man Verse schreiben.«

Erik lachte.

»O weh, die armen Verse!« bemerkte er, »also einen solchen stillen Winkel hast du dir noch in deinem Kopf referiert, während es aussieht, als ob du die schönste Ordnung gemacht hättest. Die ist wohl nur in den Staatsstuben, auf der Oberfläche. Dahinter liegt eine wunderschöne, unergründliche Rumpelkammer. Was sollen wir mit der machen?«

Sie sah ihn ganz ernsthaft an.

»Was Sie wollen,« versetzte sie treuherzig.

»Würdest du denn fraglos thun, was ich will? Auch im geheimsten, was du für dich treibst? Auch im Verborgensten deiner Rumpelkammer? Immer?«

»Immer.«

Er nahm ihren Kopf zwischen seine Hände.

»Und wenn ich sie dir nun ausräumen wollte? und wenn es zufällig gerade dein liebster Winkel wäre? und wenn es nun, irgend wann einmal, vielleicht keine bloße Rumpelkammer mehr wäre, sondern dein glückliches geistiges Zu Hause? würdest du dann auch noch ebenso antworten: ›Was Sie wollen‹?«

»Ja!« sagte sie einfach.

Erik machte eine Gebärde, wie wenn er sie in seine Arme ziehen wollte, dann aber ließ er sie frei, trat zurück und ans Fenster, neben welchem, an der Seitenwand, ein kleiner Bücherbort hing.

Ein paar Minuten vergingen.

Ruth sah ihm zu, wie er anscheinend die Titel der Bücher studierte, die sich in der langsam zunehmenden Dämmerung nicht mehr erkennen ließen. Aber Erik wußte ungefähr, was alles sich hier auf das sonderbarste einträchtig zusammengefunden hatte. Eine lateinische Grammatik aus Jonas' Nachlaß und die Märchenwelt von Tausend und eine Nacht, eine Auswahl aus Platos Werken in deutscher Uebersetzung und ein zerrissener Band alter russischem Volkserzählungen, Ueberwegs »System der Logik« und die französische Uebersetzung des Don Quixote mit den Illustrationen von Doré, und so fort.

»Warum haben Sie nie ein Buch geschrieben?« fragte Ruth plötzlich vom Fenster her.

»Weil ich es nie gekonnt habe. Bücher zu schreiben verstehe ich nicht, Ruth. Und mir schien wohl auch immer: Bücher sind tot, nur das gesprochene Wort lebt. Und ich fürchte, du wirst es auch nie können, nie verstehen, mein armes Mädel.«

»Ich? Ich will auch nicht. Ich möchte etwas andres.«

»Was möchtest du denn?«

»Ein Märchen erzählen. Ein einziges. Eines, in dem alles drin ist. Aber nicht mit Worten.«

»Das würdest du ja auch schreiben oder sprechen, malen oder meißeln müssen, wenn du es mitteilen willst.«

»Es muß noch auf bessere Weise gehen,« meinte Ruth.

»Nicht, wenn es für alle sein soll. Sonst kann man es auch wohl einem lieben Menschen an den Augen ablesen.«

»Das ist schon besser,« sagte sie und lehnte ihren Kopf gegen das Fensterkreuz zurück.

Kurze Zeit schwiegen beide.

Die Dämmerung sank tiefer. Ueber den Steinfliesen der Terrasse unter ihnen blinkte es hell auf, im Wohnzimmer wurde die Lampe angezündet.

Um den Wipfel der alten Ulme vor dem Fenster spielten die Fledermäuse. Lautlos huschten sie unter dem Dachfirst hervor und flatterten hinter Ruths Rücken hin und her im Zickzack.

Erik stand mit einemmal im Halbdunkel dicht neben ihr. Er hob die Hände und strich leise über ihr Haar hin, so daß sie sich in den weichen, lockigen Wellen verloren, und dann blieben sie auf ihren Schultern liegen, und er beugte sich tief über Ruth.

»Sage mir das nicht mehr, -- was du vorhin sagtest: daß du immer und fraglos thun würdest, was ich will,« bemerkte er mit gesenkter Stimme, »du sollst mir nicht in jedem Fall und blind folgen. -- Ich könnte ja auch ein Unrecht von dir wollen. -- Hast du daran nicht gedacht?«

Sie legte sich weit in seinen Arm zurück und schüttelte den Kopf.

Er umfaßte sie fester.

»Und wenn es doch so wäre?« fragte er fast heftig, »was würdest du thun?«

Nun erst blickte Ruth auf und sah ihn lange und ruhig an. Sie schien sich den Fall ernsthaft zu überlegen.

»Unrecht thun!« sagte sie dann laut.

Erik fuhr zusammen. Er murmelte etwas, was sie nicht verstand. Sie lachte aber über das ganze Gesicht.

»Für mich ist immer ~das~ das Rechte, was Sie wollen, -- niemals ein Unrechtes. Besser weiß ich es nicht. Ich brauche es aber auch nicht besser zu wissen.«

»Mein armes Kind,« sagte er leise.

Sie richtete sich in seinem Arm hoch. Ein lauschender Ausdruck kam in ihr Gesicht.

»Wer? ich? Warum sagen Sie das?« fragte sie mit veränderter Stimme und machte sich langsam frei. »Was ist das? Warum sagen Sie mir das alles? Ich bin kein armes Kind. Ich bin ja ~Ihr~ Kind!«

Und als er nicht gleich antwortete, faßte sie ihn plötzlich an beiden Armen und schüttelte dieselben mit leidenschaftlicher Kraft. »Bin ich es denn nicht?« fragte sie wild. »Worum soll ich nicht mehr thun, was Sie wollen? Bin ich denn nicht Ihr Kind? Nicht mehr?! Dann wäre es besser, tot zu sein.«

»Ruth!« rief er erschüttert.

Sie suchte sich zu fassen. Ihre Hände sanken von seinen Armen und schlangen sich ineinander. Dann hob sie den Kopf.

»Ich will alles thun, -- alles! Recht oder Unrecht, Gutes und Böses, -- alles! Ich will gehorsam sein bis in den Tod. Stellen Sie mich auf die Probe. Aber gehorchen muß ich Ihnen dürfen, -- Ihr Kind sein dürfen, -- zu Ihnen sagen dürfen: ich will thun, was Sie wollen. Immer! Immer! Das muß ich -- muß ich dürfen. -- -- Darf ich?«

Unwillkürlich hob sie ein wenig die gefalteten Hände. Eine Gebärde unsäglicher Demut. Aber ihr Gesicht sah dabei fast finster aus, und ihre Stimme klang wie Metall. Und nun ein ganz weicher, kindlicher Ton: »-- Darf ich?«

Erik wurde zu Mute, als schaue er plötzlich, erst in diesen vorüberblitzenden Sekunden, mit weitem Blick hinein in die verhüllte Tiefe, aus der allein Ruths Liebe geboren werden konnte. Zum erstenmal hinein in das Geheimnis ihres Wesens, -- hinein in die stumme Einsamkeit und Sehnsucht vieler, vieler Jahre, aus der mit rückhaltloser Gewalt die langgehemmte, lang aufgestaute Inbrunst hervorgebrochen war, als er in ihr Leben trat. Ihn lieben dürfen, das hieß: endlich -- endlich ~Kind sein dürfen~, gehorchen, sich hingeben, sich weggeben, auf den Knieen noch. Es hieß sammeln und ausstürzen dürfen die ganze leidenschaftliche Zärtlichkeit des Kindes, das noch keine Kindheit gehabt. Und das doch gerade dessen -- nur dessen bedurfte.

Ruths Augen blitzten ihn durch die Dämmerung an.

»Bin ich noch immer arm, -- ein armes Kind?« schienen sie ihn unverwandt zu fragen.

»Du bist nicht arm, -- mein Kind bist du, -- und darfst gehorchen, -- mir folgen, -- du sollst es immer dürfen,« sagte er heiser.

Und er öffnete die Thür nach der Treppe, über der hell das Lampenlicht aus dem Flurraum heraufschien. --

Diesen Abend zog sich Erik schon gleich nach dem Thee in sein Arbeitszimmer zurück. Klare-Bel merkte recht wohl, daß er wieder die halbe Nacht aufblieb. Obgleich doch am andern Tag der Unterricht ausfiel.

Den nächsten Morgen fragte Erik am Frühstückstisch, ob Briefe in die Stadt mitzunehmen seien.

»Willst du zur Stadt fahren? gerade heute? am Sonntag?« fragte seine Frau erstaunt.

»Ja. Ich muß selbst zwei Briefe, die dringend sind, besorgen und einen notwendigen Besuch machen,« versetzte er.

Die beiden Briefe sah Klare-Bel auf dem Nebentisch liegen. Der eine an Römer nach Heidelberg, der andere an dessen Frau nach Moskau. Beide doppelt frankiert.

Sie wagte nicht, ihn zu fragen, was er denn an Frau Römer so viel zu schreiben habe? Er machte ein so ablehnendes, verschlossenes Gesicht. Aber als er fortgegangen war, sann Klare-Bel den ganzen Vormittag traurig und besorgt diesem Gesicht nach.

Dies Wortkarge, Verschlossene kannte sie als ein schlimmes Zeichen. Erik war offen und mitteilsam, wenn er froh war; wenn er schwieg, so litt er. Und gerade dann hätte Klare-Bel am liebsten alles mit ihm geteilt. Dem Glücklichen, Frohen gegenüber fühlte sie sich leicht ein wenig gedrückt, ein wenig überflüssig. Dagegen erschienen ihr immer Leiden und Kummer als die geeignetsten Zugänge, die wohl auch sie zu Eriks Innerem hätte finden müssen, -- um ihm nahe zu kommen, um ihm notwendig zu werden. Aber gerade wenn er litt, wurde er am unzugänglichsten, -- wurde er stets abweisend, bis zur Schroffheit. Nur in seinen frohen Stunden erschloß er sich ihr.

So war es also wohl nichts für sie: weder mit der Freude, die sie ihm so gern bringen wollte, -- noch auch mit dem Kummer, den sie mit ihm getragen hätte. --

Inzwischen befand sich Erik in der Stadt bei Ruths Verwandten. Ganz gegen seine Vermutung fand er auch die Tante vor, die soeben von Wiesbaden zurückgekehrt war, um, nach kurzem Aufenthalt, zu den Ihrigen nach Livland zu reisen, wohin ihr Mann sie begleiten sollte.

»Vor Anbruch des Winters kommen wir von dort nicht mehr heim,« sagte der Onkel zu Erik, den er auf das herzlichste wieder begrüßt und erst nach längeren, zwanglosem Gespräch zu zweien in das Empfangszimmer zu seiner Frau geführt hatte. »Aber alles, was Sie mir da erzählt haben, eilt ja auch nicht von heute auf morgen, denke ich mir. Wenn Sie Ihre Absicht ausführen, Ruth ins Ausland zu senden, so ließe sich dabei der Zeitpunkt unsrer Rückkehr ein wenig mit berücksichtigen, nicht wahr?«

»Nein!« entgegnete Erik, »das, was ich von Ihnen erbitten wollte, war eben dies: mir auch hierin vollständig freie Hand zu lassen. Und für Ruth an dem Reiseanschluß festzuhalten, den ich im Auge habe. Auch wenn das ihre Abreise unberechenbar beeilen sollte. Ich weiß, daß ich Ihnen damit viel zumute. Aber wenn Sie Vertrauen zu mir haben, dann lassen Sie mich noch einmal über Ruth entscheiden, so unbedingt wie damals, als ich sie Ihnen fortnahm.«

»Ich weiß keinen Menschen aus der weiten Welt, zu dem ich mehr Vertrauen fassen könnte, als zu Ihnen,« versetzte Ruths Onkel, dem bei Eriks sonderbar bestimmtem Ton die Gemütlichkeit schwand, »und was Ruth betrifft, so habe ich von allem Anfang an das Gefühl gehabt, als ob selbst so nahe Verwandte wie wir, Ihnen ein Recht auf die Kleine abtreten müßten. Wenn Sie also so fest glauben, daß es gut an ihr gehandelt ist, handeln Sie so! Ich meinerseits will, -- wenn ich sie nicht wiedersehe, -- ich will Weihnachten einen kurzen Urlaub nehmen und unsre kleine Studentin in Heidelberg besuchen.«

»Aber ich bitte dich! nenne es doch wenigstens nicht gleich beim ärgsten Namen!« fiel die Tante ein, der die Nachgiebigkeit ihres Mannes unverantwortlich vorkam. »Ruth soll doch nicht wirklich studieren? Ich meine, mit einem Studentenplaid und kurzen Haaren, wie es hier geschieht? Bei uns in den Ostseeprovinzen wäre so etwas rein undenkbar.«

»Einstweilen soll sie lernen,« antwortete Erik etwas ablehnend, »das Weitere wollen wir ruhig ihr selbst und der Zeit überlassen.«

Sie sah ihn prüfend und mißbilligend an. Wie konnte man so etwas der »Zeit« überlassen? Hätte er noch gesagt »der Vorsehung«. Wenn er für das Frauenstudium eintrat, dann war er auch ganz sicherlich ein Atheist. Und solchen Leuten war doch wohl alles zuzutrauen.

»Ich sehe mit Verwunderung, daß mein Mann sehr sorglos darüber denkt,« bemerkte sie, als Erik schon aufstand, um sich zu verabschieden, »aber um so mehr muß ich ein Wort hinzufügen. Du sprichst so ruhig von Recht abtreten, Louis! Aber ~ein~ Recht kannst du doch nie und nimmer abtreten. Ich meine das Recht der moralischen Verantwortlichkeit. Das mag ja eine altmodische Ansicht sein. Aber ich möchte doch wissen, wie Herr Matthieux darüber denkt.«

Erik sah ihr ernst und ruhig in die kampflustig auf ihn gerichteten Augen. Zum erstenmal gefiel sie ihm. Eben die Kampflust gefiel ihm. Obwohl der Onkel Ruth lieb hatte, war sie doch ein besserer Wächter als er.

»Wenn ich Sie recht verstehe,« sagte er, »so fürchten Sie, daß ich mit meinem Recht an Ruth nicht zugleich auch alle Pflichten ihr gegenüber übernehmen würde. Wenn es etwas gibt, was Sie von dieser Furcht befreien kann, so nennen Sie es nur.«

Der Onkel sah fast verlegen aus, aber sie beachtete es nicht.

»Ich antworte Ihnen als gläubige Frau,« entgegnete sie, die stolz war auf baltische Ueberzeugungstreue, »mir bedeutet moralische Verantwortlichkeit: schuld sein wollen an einem Menschen, -- schuld an dem, was an seinem innern Menschen geschieht. Nicht zulassen, daß er Schaden daran nimmt. Wie sollte man das ohne Gott, ohne religiösen Glauben auf sich nehmen können? Wenn Sie nun Ruth fortgeben, -- können Sie eine solche Pflicht in diesem Sinne übernehmen?«

Ueber Eriks Züge ging ein Ausdruck, den sie nicht zu deuten wußte, der sie aber wider ihren Willen ergriff.

»Nun verstehen wir uns,« sagte er mit unterdrückter Bewegung, »denn eben das soll mein Recht sein: ich will schuld sein an diesem Kinde!«

Sie fand, es klang arroganter als je. Es war nichts, das ihre religiösen Bedenken beruhigen konnte. Aber ihr war dennoch, als habe er »Gott« gesagt. --

Erik ging dem Bahnhof zu. Fast kein Mensch außer ihm in den leeren Straßen; auch die letzten, die den Sommer in der heißen, ungesunden Sumpfluft der Stadt zubringen mußten, entrannen ihr am Sonntag. Nur hier und da taumelte ein Betrunkener aus der offenstehenden Thür einer Kellerschenke, oder rasselte eine vereinzelte Droschke holpernd über das schadhafte Holzpflaster, das stellenweise noch weit aufgerissen dalag und darauf wartete, daß seine alljährlichen Löcher in schöner Mosaikarbeit zugestopft würden.

Verlorene Glockenklänge, die letzten von einer der zahllosen Kirchen, zitterten über die ausgestorbenen Straßen hin, wie Grabgeläute über einer Totenstadt.

Erik ging langsam, müden Schrittes heimwärts.

»Nicht zulassen, daß sie Schaden nimmt,« wiederholte er die eben gehörten Worte. Ja, genau das wollte er doch. Noch war die Umpflanzung in einen neuen Boden möglich, wenn er seinen kleinen Baum behutsam, mit allen feinsten Würzelchen, dort eingrub. Nur so konnte er jetzt seine Gärtnerdienste an ihm thun, damit derselbe nicht Schaden nehme an seiner Entwickelung, die noch in hart und fest geschlossenen Knospen vor sich ging, -- undurchsichtig von allen Seiten.

Denn manchmal, da wachte etwas Gewaltthätiges in ihm auf, -- im pflegenden Gärtner die verbrecherische Ungeduld des Knaben, der sich am Frühling vergreift und die Knospen zerstören möchte, um zu sehen, ob eine rote oder eine weiße Blüte in ihnen schläft.

Aber er fiel sich selbst in die gewaltthätige Hand; er selbst riß Ruth sich aus der Hand.

Verdirbt denn ein Vater sein Kind, ein Mann sein Weib, ein Künstler sein Werk?

Und ihm schien: seine Liebe zu Ruth sei alles dieses.

Zu Hause hatten sie mit dem Essen auf ihn gewartet; als er kam, wurde es einsilbig eingenommen. Klare-Bels Hoffnung, Erik werde erzählen, bei wem er den Besuch gemacht, erfüllte sich nicht.

Er wußte wohl, daß er nun davon sprechen mußte. Mit ihr und mit Ruth. Es war ihm das Schwerste.

Das dachte er, als er dann endlich am Fenster seines Arbeitszimmers stand und wartend in den Hintergarten hinausblickte, wo Ruth sich mit Jonas erging: »Nur nicht sprechen, -- nur nicht grübeln, -- handeln! Sie aus den Arm setzen und forttragen. Handeln! Wer es wortlos dürfte!«

Und nun ging Jonas ins Haus.

Erik stieg zu Ruth in den Garten hinunter.

Sie saß auf ihrem Lieblingsplatz, dem Steinrand des Springbrunnens. Dort saß sie mit gebücktem Kopf und stocherte mit einem trockenen Ast im Grase.

Wie sie ihn kommen sah, warf sie ihren Zweig fort und lief ihm entgegen. Er hatte sie kaum begrüßt bei Tisch, zum verspäteten Essen, und nun schlich sich ihre Hand in die seine.

Ohne recht zu bemerken, was er that, steckte er sie mitsamt der seinen in die Seitentasche seiner Joppe.

Ruth lachte darüber und blickte zu ihm auf, aber als sie den ernsten, beinahe strengen Ausdruck seines Gesichtes sah, verstummte sie ebenso plötzlich.

Sie gingen einige Schritte dem kleinen Gehölz zu.

»Heute war ich bei deinen Verwandten, Ruth,« sagte Erik, »sie waren beide da. Ich wollte sie einmal etwas auf das hin ausfragen, was wir in den letzten Monaten schon öfters miteinander besprochen haben. Weißt du nicht? Ich meine daraufhin, ob du nicht einmal im Auslande tüchtig weiterlernen könntest.«

Sie sah ihn erwartungsvoll an. Dies da interessierte sie sehr und ein wenig beunruhigte es sie auch. Denn es handelte sich doch eigentlich erst um ein ganz allgemein gehaltenes, unbestimmtes Zukunftsbild, -- nicht um etwas, was schon erwogen und besprochen werden mußte.

»Nun? und was meinten sie darauf?« fragte Ruth gespannt, als er schwieg.

»Sie haben nichts dagegen einzuwenden, Ruth. Nichts Ernstliches. Da ist es denn Bernhard Römer gewesen, an den wir dabei gedacht haben. Dort wüßte ich dich im richtigen Hause geborgen. Es wäre fast so, als wenn ich selbst bei dir bleiben konnte.«

Ihre Hand, die er noch umfaßt hielt, erkaltete in der seinen.

»Ja, -- aber -- das ist ja noch so lange hin!« meinte Ruth ganz langsam, und dann immer schneller, in wachsender Unruhe: »Es ist doch noch lange hin? Sehr lange? Ich soll doch nicht -- bald fortgehen? ~Von hier~ -- -- fortgehen!«

Er umschloß ihre Hand fester und ging auf die Bänke zu, die unter den Birkenbäumen standen.

»Komm zu mir,« sagte er sanft, »setze dich zu mir her, mein Liebling, und laß uns ruhig darüber sprechen. Ganz ruhig, -- hörst du?«

Sie folgte ihm schweigend, aber ihre Augen hingen unverwandt, mit tausend aufgestörten bangen Fragen, an seinem ernsten Gesicht.

»Sieh, Kind,« fuhr Erik fort, »wenn wir hier, während unsrer gemeinsamen Arbeit, an deine Zukunft dachten, dann schwebte sie dir wie ein erwünschtes, lockendes Bild vor. Ich wollte, daß du dich später weiter entwickelst, und du wolltest es auch. Ich dachte oft bei mir, wenn ich dir zusah: manches von dem, was ich selbst einst erstrebt, könntest, in andrer Form, du einst verwirklichen. Aber was so, als Zukunftsmöglichkeit, in der Ferne stand, wird doch näher rücken müssen, bis es unwiderrufliche Wirklichkeit und Gegenwart geworden ist. Und ich wünsche, daß du diesem Gedanken jetzt nahe trittst, mein Kind.«

»-- -- Wie nahe -- -- ist es denn?« fragte Ruth mißtrauisch, aber kaum war es ihr entschlüpft, als sie ihre Hand aus der seinen riß und ihre beiden Hände flach gegen die Ohren preßte.

»Nicht!« murmelte sie undeutlich, »ich will es nicht wissen! bitte, nicht! bitte, bitte, nicht weitersprechen.«

Einen Augenblick schloß er die Augen.

Dann faßte er sanft nach ihren Händen und zwang dieselben zu sich nieder.

»Es hilft nichts, mein Kind,« sagte er fest, »es hilft nichts, sich vor etwas Unwiderruflichem zu verschließen. Gerade hiervon werden wir weitersprechen. Denn, je mehr du noch davor zurückscheust, desto dringender, desto eher muß es geschehen.«

Ruth war sehr blaß geworden.

Ein unbestimmtes Grauen stieg dunkel in ihr auf. Vor etwas, was sie noch nicht fassen, nicht deutlich begreifen konnte, was aber vor ihr empordämmerte, -- unerwartet, unversehens, aus dem Nichts, -- schattenhaft, gleich einem Riesengespenst.

»Ich kann nicht!« stieß sie hervor. »Es kann ja so nicht sein! Ich will nicht, daß es so ist. Ich kann nicht!«

Er beugte sich zu ihr und suchte ihren Blick.

»Wirklich nicht?« fragte er ruhig; »auch nicht, wenn du weißt: ich will es? Auch nicht, wenn ich selbst es bin, der dich bei der Hand nimmt, dich vor etwas hinstellt, das dir schwer fällt, damit du lernst, es herankommen zu sehen, ohne davor fortzulaufen?«

Sie schmiegte sich an ihn und versteckte den Kopf an seiner Schulter.

»Ich fürchte mich,« sagte sie, wie ein Kind im Dunkeln, »-- irgend etwas Schreckliches ist da, -- seit gestern ist es da, -- und kommt heran, immer näher, -- ganz dicht heran, -- ganz nahe. Wie ein Ungeheuer, das sich um mich ringelt. -- Ist es etwas Schreckliches -- --?«

»Nicht das, was du gestern fürchtetest,« sagte er leise, »-- nur das, was du gestern selbst wolltest, selbst fordertest. Weißt du nicht, was du mir versprachst? die Probe stellen. Wenn ich es nun thue, Ruth, -- ziehst du dein Versprechen zurück?«

»Nein!« entgegnete sie rasch und richtete sich auf. Dagegen gab es keine Auflehnung. Nur Gehorsam.

»Worin besteht die Probe?« fragte sie entschlossen, »was soll ich thun?«

Er antwortete nicht gleich. Er hatte die Brauen zusammengezogen, und seine Zähne gruben sich in die Lippe, als litte er körperlichen Schmerz.

Ein paar Augenblicke verharrten sie schweigend bei einander.

Ein kühler Luftzug strich durch die Bäume und warf ein rundliches gelbes Birkenblatt nach dem andern ihnen in den Schoß. Mühsam schien die Sonne durch breite weiße Wolkenmassen in den Garten, und aus den Vogelnestern ringsum unterbrach hin und wieder ein kleiner, satter Ton die Stille um sie.

Da antwortete Erik mit einer Stimme, die fast rauh klang: »Du sollst dich in einer großen Sache ebenso tapfer erweisen, wie du dich einmal in einer kleinen erwiesen hast. Du sollst thun, was du schon einmal thatest, als dir das langsame Herankommen, -- Näherkommen von etwas Gefürchtetem bevorstand. Es war damals, als Jonas uns die Schlange ins Haus brachte. Sie flößte dir solchen Schrecken ein. Weißt du nicht mehr, was für ein Mittel deine eigene Tapferkeit dagegen fand?«

»Nein!« sagte sie stutzend und blickte auf, »was war das für ein Mittel?«

»Du sagtest: ›Dann lieber -- gleich!‹«

Ruth sprang jäh von der Bank auf und machte eine wilde Bewegung gegen ihn hin, als ob sie ihn noch rechtzeitig an etwas hindern wollte.

Dann, ohne einen Laut der Erwiderung, brach sie vor ihm in die Kniee, in das welke Augustlaub, das zu seinen Füßen lag.

»Ruth!« murmelte er angstvoll und breitete seine Arme um sie, »mein Kind! mein Liebling! hörst du mich?«

Aber sie hörte nicht mehr. Ihr Kopf fiel zurück. Sie hatte das Bewußtsein verloren.

Inzwischen kam Jonas in den Garten gelaufen, der vom Fenster aus beobachtet hatte, wie der Vater mit Ruth in das kleine Gehölz hineingegangen war.

Wie versteinert stand er still, als er jetzt Erik zwischen den Bäumen hervortreten sah und Ruth mit geschlossenen Augen regungslos in seinen Armen. Ihre rechte Hand hatte der Vater um seinen Nacken gelegt, die linke hing schlaff herunter.

»Geh voraus!« gebot Erik dem Knaben, »ohne Lärm. Halte mir die Thüren offen. Ich muß Ruth auf ihr Bett tragen.«

Jonas blieb jegliche Frage in der Kehle stecken; er rannte voraus, nicht ohne sich fortwährend nach dem Vater umzuschauen, und ins Haus hinein. Dort lief er, ohne die Mutter oder Gonne zu alarmieren, die Holztreppe zu Ruths Giebelstube hinauf. Als Erik mit Ruth in den Armen oben ankam, stand Jonas wartend an der weitgeöffneten Thür, durch welche man das schmale weiße Bett mit den zurückgeschlagenen Decken sehen konnte.

Jonas blickte dem Vater ängstlich bittend ins Gesicht; er wäre so gern mit hineingegangen, um bei Ruth zu bleiben. Aber Erik ging schweigend an ihm vorbei und zog die Thür hinter sich zu.

Dieser Augenblick prägte sich ihm mit merkwürdiger Gewalt ein: wie der Vater, Ruth an der Brust, so stumm an ihm vorüberschritt, während ~er~ zurückbleiben mußte.

Im Blick und Ausdruck des Vaters empfand er etwas Außerordentliches, einen starren, wortlosen Ernst, -- so, wie wenn Ruth schon so gut wie tot sei.

Jonas überlief es kalt.

Er klammerte sich an den Thürgriff und lauschte mit zurückgehaltenem Atem. Anfangs unterschied er nichts. Dann hörte er Eriks Stimme, halblaut, kurz, sehr bestimmt im Ton. Sie wiederholte sich. Darauf eine Pause, -- und plötzlich ein Klagelaut drinnen, ein einziger Laut, aber so schmerzlich, daß den Knaben Entsetzen faßte.

Was that man mit Ruth, mit seiner lieben Ruth? Was that der Vater ihr an? Etwas Furchtbares mußte es sein. Etwas Furchtbares mußte heute im kleinen Gehölz vor sich gegangen sein.

Und er durfte die Thür nicht aufstoßen, er wagte es nicht. Aber eine rasche, wilde Empfindung, wie plötzlicher Haß, loderte unverstanden in ihm auf: daß er ein Knabe war, und der Vater ein Mann! Daß er nicht eindringen durfte mit gleichem Recht, -- mit Gewalt!

Aber ebenso rasch erlosch sie wieder. Ruth konnte nichts geschehen, wenn sie bei seinem Vater war.

Jonas schlich sich hinunter, in das kleine Zimmer von Klare-Bel neben der Wohnstube. Er konnte nicht allein sein.

Dort setzte er sich am Eingang auf die äußerste Kante eines Stuhles und brach in Thränen aus.

»Ruth ist halbtot, Mama!« sagte er außer sich, »ach Mama, sie stirbt! Die Augen hat sie schon zugemacht. Und Papa, -- ich weiß nicht, was Papa thut, aber ganz bestimmt thut er ihr weh. Sie darf aber nicht sterben! Vorhin war sie ja noch so vergnügt und raschelte mit mir durch die Blätter im Garten!«

Klare-Bel war nach diesem Bericht nicht weniger erschrocken als er selbst, und mit ängstlicher Spannung warteten sie darauf, ob Erik nicht bald herunterkäme. Aber es dauerte noch geraume Zeit, bis er kam.

»Um Gottes willen, was ist denn mit Ruth geschehen?« rief sie ihm in großer Unruhe entgegen.

»Sei nur ruhig; es war eine Ohnmacht,« versetzte Erik und gab Jonas einen Wink, hinauszugehen. Dann trat er an seine Frau heran und sagte: »Ich mußte Ruth eine Mitteilung machen, auf die sie nicht genügend vorbereitet war. Jetzt mußt auch du es erfahren: Ruth geht schon in diesen Tagen fort. Nach Heidelberg, zu Römer ins Haus.«

Klare-Bel erhob sich ein wenig auf ihren Kissen und sah ihn voll tiefen Staunens an.

»Ist das dein Ernst? Du gibst Ruth aus der Hand? Aber was willst du denn ohne Ruth machen? Kannst du sie denn entbehren?«

»Das muß ich doch können, Bel.«

Im beginnenden Zwielicht vermochte sie nicht seine Züge genau zu erforschen. Aber dieselben kamen ihr vor wie aus Stein gehauen. Und diesen Ausdruck kannte sie.

»Erik!« sagte sie ängstlich, »thu nur nichts so gewaltsam. Du siehst ja, daß es sie krank macht. -- Warum siehst du so hart aus, Erik?«

»Hart?« Er fuhr sich mit der Hand über die Stirn; »für mein Aussehen kann ich nicht. Aber ängstige dich um nichts. Ruth wird morgen gesund sein, und auch gefaßt. Für ihre Haltung stehe ich ein. Aber sei gut und freundlich zu ihr. Ich muß auf ein bis zwei Tage verreisen.«

»Verreisen? Du reisest fort, Erik? Wohin?«

»Nach Moskau.«

»Zu Frau Römer?« fragte sie lebhaft.

»Ja. Ihr soll Ruth sich anschließen. Und sie wird sich wahrscheinlich hier nicht mehr aufhalten. Ich muß daher alles mit ihr verabreden und besprechen. Mündlich.«

Klare-Bel schwieg. Es wurde dämmerig im Zimmer, und draußen im Flurraum hörte man Jonas unruhig auf und ab gehen.

Da, ganz leise, fühlte Erik seine Hand von Klare-Bel erfaßt.

»Erik!« flüsterte sie, »-- laß mich dich bitten: lasse sie noch ein Weilchen bei uns. -- -- -- Auch ich werde sie ja vermissen, Erik!«

»Du -- -- -- Bel?«

»Ja. Denn sie hat dich so glücklich gemacht.«

Er zog ihre Hand an sich, und an den Mund und küßte sie voll Scham und Ehrfurcht.

»Ich danke dir für diese Bitte. Ich danke dir, Bel. Aber es kann nicht sein.« --

Er zog sich zurück, um Ruths Onkel die definitive Entscheidung mitzuteilen. Dann packte er eine Handtasche, und eine Stunde später war er fort. Er reiste noch mit dem Nachtzuge nach Moskau ab.

In dieser Nacht lag Klare-Bel viel wach und dachte an Ruth und an Erik. Sie hatte bestimmt geglaubt, Ruth werde bis zum Spätherbst bei ihnen im Haus und dann, vom Hause ihres Onkels aus, nach wie vor in engster Verbindung mit ihnen bleiben. Wie oft hatten sie darüber gescherzt, ob sie dann, später, mit Jonas zusammen auf die Universität abgehen solle? Erik hatte kein Wort davon gesagt, daß seine Absichten wohl von Anfang an andre waren. Ganz plötzlich kam er jetzt mit ihnen heraus.

Aber Klare-Bel fiel es gewiß nicht ein, Kritik an dieser Handlungsweise zu üben. Da er es so wollte, mußte es so wohl gut sein. Gut für Ruth. Er liebte sie so sehr, er konnte nur ihr Bestes dabei im Auge haben. Auch dabei, daß es so unerwartet über sie kam.

Aber gern wäre sie jetzt zu Ruth hinaufgegangen und hatte sie geliebkost und getröstet. Sie nahm sich vor, es den nächsten Tag zu thun. Zum erstenmal fühlte sie eine echt mütterliche Zärtlichkeit für Ruth, -- nicht nur das indirekte Interesse, das durch Erik hindurchging und alles auf ihn bezog. --

Der Morgen war herbstlich und grau, die Terrasse noch feucht von den kalten Nebeln der Nacht. Man mußte das Frühstück im Wohnzimmer einnehmen. Ruth fand sich zur gewöhnlichen Zeit dort ein; sie war blaß und ernst, aber gesund, wie Erik es gesagt hatte, und ganz gefaßt und still.

Als sie, noch vor Jonas, hereinkam, streckte Klare-Bel ihr die Arme entgegen: »Komm zu mir,« sagte sie liebevoll, »sei nicht traurig, denke nicht an die Abreise. Noch bist du hier!«

Ruth sah auf, ohne daß sich eine Miene in ihrem stillen Gesicht verändert hätte, und schüttelte den Kopf.

»Ich bin schon fort!« entgegnete sie.

Diese Antwort ergriff Klare-Bel sehr. Ihr schien, es lag etwas Schmerzlicheres darin, als in Klagen und Thränen, -- etwas, das die bloße Ankündigung der Trennung schon mit ganzer Wucht als Trennung empfand und nicht mehr davon los konnte.

Sie fühlte heißes Mitleid in sich aufsteigen. Und jetzt kam Erik ihr doch hart vor. Wie konnte er nur wollen, daß Ruth so von Haus zu Haus, von Hand zu Hand ging. Unwillkürlich suchte sie nach Worten, die wahrhaft trösten könnten. Gab es keine solchen? In ihrer Ratlosigkeit griff sie nach dem Höchsten, das sie gekannt hatte.

»Wir wissen alle nicht, wo wir bleiben, und was mit uns geschieht,« sagte sie zögernd, »wir wissen es nie. Es steht in Gottes Hand. Aber wir sind auch nie allein, wo wir auch hingehen. Gott ist allgegenwärtig.«

Ruth lächelte flüchtig.

»Ja,« versetzte sie traurig, »was kann es helfen, daß Gott allgegenwärtig ist, wenn die Menschen es doch nicht sind? die Menschen, von denen wir fortgehen.«

Klare-Bel schwieg peinlich berührt. Sie gab es auf, Ruth trösten zu wollen. Wenn diese so etwas sagte, klang es kindisch und vermessen zugleich. Wer mochte darauf antworten?

Ueber Eriks Abwesenheit äußerte Ruth kein Wort; obgleich er ihr nicht davon gesprochen hatte, wunderte sie sich doch nicht darüber, ihn nicht zu sehen. Es mußte wohl so sein: war doch alles in Auflösung begriffen.

Jonas erfuhr nichts von der bevorstehenden Trennung. Niemand teilte es ihm mit. Er hörte nur, daß Ruth wieder gesund sei, aber das glaubte er nicht. Wie konnte sie gesund sein, wenn sie doch so ganz verwandelt war seit gestern. Und nicht nur Ruth, alles schien ihm wie verwandelt.

Gern hätte er sie gebeten, ihm zu sagen, was gestern geschehen sei, aber sie ging den ganzen Tag mit so in sich gekehrtem, fremdem Blick an ihm vorbei, daß er es nicht herausbrachte. So begnügte er sich damit, so oft er nur konnte, neben ihr zu sitzen, den Arm um ihre Stuhllehne gelegt, und von Zeit zu Zeit behutsam und zärtlich ihre Hand zu streicheln. Manchmal duckte er sich auch und küßte ihre Hand, ohne daß Ruth es beachtete.

Daß Erik nicht zu Hause war, verstärkte in Jonas noch die Empfindung, daß er über Ruth zu wachen habe, wie ein getreuer Wächter. Am liebsten hätte er sie mit Leib und Leben verteidigt, aus Todesgefahr errettet, -- wenn er nur gewußt hätte, wovor und vor wem.

Spät abends, als sie längst in ihre kleine Stube hinaufgestiegen war, patrouillierte Jonas noch unermüdlich im Garten vor ihrem Fenster auf und ab, und es that ihm leid, daß so absolut nichts passieren wollte. Endlich verfügte er sich mit einem krampfhaften Gähnen in sein Bett, aber er schlief unruhig und erwachte bald wieder.

Da sah er deutlich im Garten vor der Terrasse Ruths Fensterkreuz auf einem hellen Lichtfleck abgezeichnet: bei ihr mußte jetzt, gegen Morgengrauen, noch Licht brennen.

War sie krank? unglücklich?

Er hielt es im Bett nicht aus. Im Nu war er in seinen Kleidern und kletterte geräuschlos aus dem Fenster. Vor der Terrasse stand die alte Ulme; sie besaß einen bequemen Sattel, von dem aus zwei mächtige Aeste sich gabelten. Wie eine Katze glitt Jonas am bemoosten, von den starken Niederschlägen der Nacht schlüpfrig gewordenen Stamm hinauf.

Verlangend blickte er in den gelblichen Kerzenschein, der aus der Giebelstube fiel.

Ruth saß auf dem Bett. Vollständig angekleidet, so wie sie hinaufgestiegen war, saß sie noch da; die Arme vor sich hingestreckt, die Hände auf den Knieen gefaltet, kehrte sie Jonas fast voll ihr Gesicht zu. Den Kopf ein wenig erhoben, schaute sie weit hinweg über die dunkeln Wipfel des Gartens.

Sie schaute so geheimnisvoll, wie in eine unendliche, verklärte Ferne. Und um die festgeschlossenen Lippen lag ein stiller Ausdruck, -- lag Ergebung.

Jonas starrte auf sie hin mit weitgeöffneten Augen. Er war so im Bann des ~einen~ Bildes, daß er gar nicht mit Bewußtsein wahrnahm, was das flackernde Licht auf dem Tisch sonst noch beleuchtete. Er sah nicht, daß der Tisch selbst abgeräumt war, die Stühle zusammengeschoben, -- nicht, daß auf ihnen ein offener, halbgefüllter Koffer stand, und daß die Wände, ohne den Schmuck seiner Bleistiftsskizzen, kahl und leer auf Ruth niederblickten.

Er sah nur sie, seine lustige Ruth, wie in dem Bilde einer betenden Heiligen, und alles, was in dem gestrigen Erlebnis seine schwerfällige Knabenphantasie in mächtige Schwingungen versetzt hatte, gewann erneute Gewalt über ihn. Ruth selbst wurde zu etwas Geheimnisvollem und Leidendem für ihn; aus der fröhlichen Spielgefährtin zu einem Wesen, das seine Schwärmerei wachrief.

In Gedanken hörte er wieder den leisen Klagelaut von gestern; er sah sie auf dem Bett daliegen, den Vater über sie gebeugt, -- und sein Herz schlug beklommen. Er vermochte die Augen nicht vom Fenster abzuwenden.

Die Nacht war kalt; vom Rasen unter ihm stieg der Nebel auf. Schmal und blaß hing die kleine Mondsichel am östlichen Himmel, und aus dem Gehölz klang verschlafen ein Rabenkrächzen.

Jonas fror; er schob die Hände unter seine dünne Sommerjacke und drückte sich dichter gegen die breiten Aeste, deren Feuchtigkeit ihn allmählich durchdrang. Dabei fiel ihm der eine seiner roten Pantoffeln klatschend aus die Terrasse nieder.

Er zog den nackten Fuß unter sich und überlegte ärgerlich, ob er hinuntersteigen solle, den verlorenen Schuh zu holen. Da bewegte Ruth sich. Das Geräusch draußen hatte sie aus ihrer Traumversunkenheit geweckt.

Sie stand langsam auf und löste ihre Bluse von den Schultern.

Ein Arm hob sich heraus und, unter dem von keinem Schnürleib bedeckten Hemde, die zarte Wölbung der Brust.

Einen Augenblick stand sie mit gesenktem Kopfe still. Dann hob sie die entblößten Arme hoch über sich, stürzte vor ihrem Bett auf die Kniee und warf sich mit ausgebreiteten Armen darüber hin, den Oberkörper langgestreckt, in den Kissen vergraben. So blieb

sie regungslos liegen.

Jonas verharrte unbeweglich und hielt den Atem an. Er hatte den Schuh, er hatte die Kälte vergessen.

Vor seinen Augen flimmerte es.

Weit vorgebeugt, die Finger hineingekrallt in die belaubten Zweige, um nicht zu fallen, starrte er mit klopfenden Schläfen nach dem Bett.

Ueber ihm glomm langsam der Morgen herauf. --

* * * * *

Als Gonne früh morgens, beim Fegen der Terrasse, den Pantoffel auflas, war Jonas längst frostbebend in sein Bett gehinkt, halb bewußtlos vor Kälte und Erregung. Er gab sich den nächsten Tag große Mühe, ein starkes Unwohlsein zu verbergen, konnte aber vor Heiserkeit kaum sprechen, und seine Augen glänzten im Fieber. Auf Klare-Bels besorgtes Drängen und Fragen bekannte er, die Nacht im Garten gesessen zu haben.

Nach dem Essen warf er sich angekleidet auf sein Bett.

Um diese Zeit kehrte Erik nach Hause zurück. Klare-Bel erwartete ihn erst mit Einbruch der Nacht. Aber er hatte auch von Moskau den Nachtzug benutzt.

Ruth stand in seinem Arbeitszimmer, bemüht, ihre Papiere und Hefte unter den seinen herauszusuchen, um sie einzupacken. Was war nun seines, -- was ihres? Der ganze Inhalt ihrer Studien in Niederschriften von seiner Hand, -- der ganze Inhalt seiner Pläne und Arbeiten für den Winter, seiner Gedanken und Vorträge wiedergegeben, niedergeschrieben von ihrer Hand.

Da vernahm sie unerwartet im Flur einen raschen, festen Schritt.

Die Thür von Eriks Zimmer in den Flur flog auf, und Ruth an seine Brust.

Sie hatte über Zweck und Dauer seiner Reise nicht nachgedacht. Von der einen Gewißheit hypnotisiert, daß sie fort mußte, nahm sie alles passiv hin.

Um so mächtiger jedoch wirkte der plötzliche Anblick Eriks jetzt auf sie. In diesem einen Augenblick vergaß sie alles, -- in diesem einen Augenblick siegte die Gewalt der Gegenwart über jeden Kummer, der bevorstand, -- leugnete ihn, vernichtete ihn, -- in diesem Augenblick wurde alles, -- alles gut.

Sie vermochte nichts zu denken, als daß er da war. Und daß sie bei ihm war.

Fest, -- fest schlangen sich ihre Arme um seinen Nacken, fest barg sich an seiner Schulter ihr Gesicht.

So stehen bleiben, -- für immer so stehen bleiben, festgewurzelt für immer an dieser Stelle, hineingeschmiegt in die weiten, weichen Falten des geöffneten Reisemantels, -- nichts fühlen, nichts vernehmen, als den starken, dumpfen Herzschlag, der ihr entgegenpochte, -- für das ganze Leben nichts -- nichts mehr.

Sie wechselten kein Wort.

Aus Eriks Hand war die Reisetasche auf den Boden geglitten; stumm hielt er Ruth an der Brust, schwer atmend und den Kopf niedergebeugt auf ihr Haar.

Und plötzlich gruben sich seine Hände hart in ihre Schultern, um ihre Hüften, und umschlossen sie mit so gewaltthätigem Griff, daß es wie Schmerz und Ersticken über sie kam, -- als müsse er sie nun zerbrechen. Zerbrechen unter seinen Händen und an seiner Brust, -- sterben, -- nicht fortgehen, -- dachte sie, und es überflutete sie mit einem jauchzenden Glücksgefühl, wie sie es nie gekannt.

Erik sah sie lächeln.

Er verlor die Besinnung.

»Wahnsinn!« schoß es ihm wie Feuer durch den Kopf, »Wahnsinn! Wahnsinn, sich zu lassen, wenn man sich liebt.«

Eine Sekunde lang, -- dann ließ er sie so jäh los, daß sie zurücktaumelte. --

»Erik!« rief Klare-Bels Stimme durch das Nebenzimmer, »Erik, bist du wieder da?«

Er hing den Mantel an den Ständer, dann öffnete er die Thür zu der Wohnstube, in der sie lag.

»Denke nur, Erik, Jonas ist inzwischen krank geworden, -- so schwer erkältet, -- hoffentlich ist es nicht schlimm. Er hat -- -- aber was ist dir?«

Er stand da wie ein Betäubter, das Blut in den Augen.

»Nichts. Ein Schwindel,« murmelte er, setzte sich an den Tisch und stützte den Kopf auf die Handflächen.

»Das ist diese übertriebene Eile!« klagte sie besorgt, »-- daß es mit solcher Windeseile vor sich gehen soll. Wann ist es denn nun, daß sie reist, Erik?«

»Morgen, -- um Mittag,« sagte er leise.

»Mein Gott, so schnell ist es aber doch rein unmöglich! Denke doch nur, was es für eine solche Abreise alles zu ordnen und zu überlegen gibt. Ruth braucht doch gewiß noch manches, was für sie beschafft werden muß.«

»Es kann alles in Heidelberg beschafft werden.«

»Nun ja, Erik. Aber wenn du wüßtest, wie tief es ihr geht. Wie blaß und elend sie ausgesehen hat, gestern und heute. Sie ist doch nur zart.«

»Hör auf!« sagte er zwischen den Zähnen.

»Ach, Erik, ich widerspreche dir ja nicht! Das thue ich ja niemals! Sie thut mir nur so leid. So allein ist sie, und so liebebedürftig. Und nun: von Haus zu Haus, von Hand zu Hand. Und wenn sie nun erkrankt, --«

»Hör auf!« unterbrach er sie außer sich und sprang auf, und warf den Stuhl zurück, daß er zu Boden schmetterte, »hör auf, Bel! Es ist genug! Ich will es so!«

Damit verließ er das Zimmer.

Mit erschrockenen Augen sah sie ihm nach. Erik war fast immer sanft gegen sie, obschon -- oder vielleicht weil -- ihr Wille gegen den seinen nie recht in Betracht kam. In so heftigem Ausbruch hatte sie ihn lange nicht mehr gesehen, -- wohl seit ihrem Krankenlager nicht mehr. Kranke sind gute Lehrmeister!

Nur in den ersten Jahren ihrer Ehe. Da war ihm der rasche Zorn noch nicht verraucht, da ward er leicht heftig, wenn seine Frau nicht ganz dem entsprach, was er erwartet, was er mit ihr gewollt hatte.

Seltsam: damals erschreckte es sie nicht, -- nein, mehr noch, so wunderlich es auch sein mochte: sie liebte diesen Zorn. So deutlich fühlte sie, daß Eriks Liebe damit verknüpft war. Gegen einen ihm gleichgültigen Menschen konnte er nie heftig werden. Mit dem Interesse an einem Menschen wuchs in dieser herrischen Natur das Verlangen, ihn zu formen, zu gestalten, nach seinem Willen umzuprägen. Liebe und Härte fielen zusammen.

Klare-Bel hatte ein russisches Geschichtenbuch gesehen, da befanden sich auf dem dazu gehörigen Titelbilde zwei Bauersfrauen: die eine, im roten Sarafan, auf die ihr Eheliebster mit einem Weidenprügel dreinschlug, lachte über das ganze Gesicht; die zweite, im blauen Sarafan, saß daneben am Weg auf einem Stein, sah neidisch zu und weinte sich die Augen aus, indes ihr Liebster mit einer andern spazieren ging.

Das war gewiß eine dumme Geschichte. Aber diese beiden Bauersfrauen konnte Klare-Bel gut verstehen.

Niemals sollte sein Zorn sie schrecken: nur, daß er mit seinem Zorn seiner Liebe vergäße. --

Der Tag schlich langsam zu Ende. Es war so still im Hause, als ob keiner darin anwesend sei. Erik hatte lange bei Jonas gesessen, ihn genau angesehen, alles Notwendige veranlaßt und den heftig Widerstrebenden gezwungen, sich ganz zu Bett zu legen. Es handelte sich um eine starke Halsentzündung mit beträchtlichem Fieber.

Ruth stand auf dem Flur, gegen das Treppengeländer gelehnt. Sie wußte selbst nicht, warum sie dort stand. Wahrscheinlich weil alle Thüren sich in den Flur öffneten. Und aus einer der Thüren mußte doch endlich Erik kommen. Und wenn er kam, mußte er doch zu ihr treten. Sich nach ihr umwenden. Er mußte doch einsehen, daß es unmöglich war, so fremd aneinander vorüberzugehen, wie er es heute abend that.

Sie wollte so wenig: nur seinen Blick auf sich gerichtet sehen wollte sie, -- nur seine Hand fühlen, einen Augenblick lang.

Seitdem Erik sie an sich gerissen, und von sich gestoßen hatte, war eine ratlose Verzweiflung über Ruth gekommen. Die äußere Trennung, die nahm sie ja hin, wie etwas Furchtbares, aber Unabwendbares, weil er es so forderte. Aber daß er sie ganz plötzlich auch innerlich von sich losriß, das konnte sie nicht ertragen. Ihn den Blick absichtlich fortwenden zu sehen, -- ohne ein Wort der Liebe für sie, ihn wie einen Fremden dastehen zu sehen, -- das konnte sie ganz gewiß nicht ertragen.

Zur Schlafenszeit trat Erik aus dem Wohnzimmer heraus. Als er Ruth an der Treppe bemerkte, sagte er ihr gute Nacht. Sie machte eine Bewegung auf ihn zu, ihre Augen schauten dunkel und vorwurfsvoll zu ihm auf. Aber er sah ihr nicht in die Augen. Er gab ihr nur flüchtig die Hand. Dann ging er an ihr vorüber, zu Jonas hinein.

Bald darauf siegte die Uebermüdung über ihn; wider Erwarten fiel er in einen schweren Schlummer. Aber aufregende und häßliche Träume erfüllten seinen Schlaf, furchtbare Träume, die seinen Körper mit kaltem Schweiß bedeckten.

Er sah Ruth vor sich, gealtert, verwelkt, mit gefurchten Zügen und gekniffenen Lippen, mit Lippen, wie sie eine leere, liebeleere Jugend gibt; er sah sie in einem lächerlichen Bilde, wie in einer Theaterposse, als tugendsame hysterische alte Jungfer, mit der unerfüllten Sehnsucht nach Zärtlichkeit im erloschenen Blick. Und da, als er in der Angst des Traumes gewaltsam seine Augen von der Fratze wandte, -- fort, einem andern Ruthbilde zu, -- da wandelte es sich vor ihm -- zu nackter, entblößter Schönheit. Nackt sah er Ruth, -- und schamlos, fremden Männern preisgegeben, -- einen weißen Körper, der nicht der ihre war, ein lachendes Antlitz, das nicht das ihre war, -- und doch wußte er: es sei Ruth.

Er erwachte mit einem stöhnenden Laut. Und noch aus dem Traume heraus hörte er küssen und lachen.

Aber das leise Stöhnen wiederholte sich, als habe es ein Echo an den Wänden des Zimmers gefunden, und ein unterdrücktes Weinen schlug an Eriks Ohr.

Er richtete sich auf und lauschte.

Das Weinen kam aus Jonas' Bett, welches neben der offenen Verbindungsthür beider Stuben stand. Man konnte deutlich hören, wie er es in den Kissen zu ersticken suchte.

Erik ermunterte sich völlig. Er machte Licht und näherte sich Jonas' Bett. Als dieser ihn kommen hörte, verkroch er sich nur tiefer in seine Decken.

»Hast du Schmerzen?« hörte er den Vater fragen, »bist du kränker geworden?«

»Ich bin nicht krank!« murmelte Jonas, »es ist unnütz, mich mit Gewalt im Bette zu halten. Ich weiß doch alles! Ich weiß jetzt alles! Es hat nichts genützt, es vor mir zu verheimlichen! Und was ich noch nicht wußte, habe ich gehört! Ich habe gehorcht und habe es gehört!«

Erik schwieg einen Augenblick betroffen.

»Du sprichst im Fieber,« sagte er dann, »was weißt du denn, was hast du gehört?«

»Daß sie fortgeht! Daß sie morgen fortgeht!«

Und er wühlte sich schluchzend in seine Kissen.

Erik tastete nach seinem Gesicht und legte ihm die Hand besorgt an die trocken brennende Stirn. Aber Jonas stieß seine Hand zurück.

»Nein!« sagte er fast keuchend, -- »du willst es ja, -- du bist es ja -- schuld, daß sie fortgeht. Vor dir schützen muß ich Ruth, -- schützen, denn was weißt du, -- wie ihr zu Mute ist. Du weißt nicht, hast nicht gesehen, -- wie sie daliegt die Nächte, -- halb ausgekleidet, an ihrem Bett, -- wie gestern.«

Erik preßte die fieberglühende Hand in der seinen zusammen, so daß Jonas die Zähne mit Gewalt aufeinanderbiß, um den Schmerz zu beherrschen.

»Was hast du -- gestern -- gesehen?« fragte Erik mit heiserer Stimme.

Jonas setzte sich auf.

»Sie kniete vor ihrem Bett,« sagte er traurig, »vielleicht weinte sie, -- oder betete, -- so geheimnisvolle Augen hatte sie, -- und ich habe mit ihr gewacht, -- ganze Nacht, heimlich, oben, in der alten Ulme vor der Terrasse.«

Erik sprach kein Wort.

Aber nach einer langen Pause hob er die Hand, und leise strich er Jonas über Stirn und Haar hin. Diesmal wurde die Hand nicht zurückgestoßen. Die sanfte, liebkosende Bewegung des Vaters, der ihn so selten liebkoste, empfand Jonas als ein wortloses Verstehen und Mitfühlen, das ihn um die letzte Fassung brachte.

Und plötzlich warf er die Arme um den Nacken des Vaters. Und wie ein unaufhaltsamer Strom, fieberheiß, halbverständlich, brachen die Worte aus ihm hervor, überstürzten sich und verklangen in einem Stammeln: »Papa, lieber Papa, hilf mir! Ich kann es nicht aushalten, daß sie fortgeht! Ich war böse auf dich, -- nimm's nicht übel, -- hilf mir! halte sie, Papa! sie bleibt da, wenn du es willst. Früher war ich mal eifersüchtig auf Ruth, ich glaubte, daß du sie mehr liebst als mich. Aber es schadet nichts, wie sehr du sie auch liebst, Papa! Denn ich liebe sie ja auch viel mehr als dich! Mehr als dich! Mehr als alles auf der Welt!«

Erik löste leise die Hände von seinem Nacken und hielt sie fest.

»Nimm dich zusammen!« sagte er halblaut, aber mit der eindringlichen Stimme, der Jonas unbedingt zu folgen gewöhnt war, »du darfst nicht hier liegen und dich so haltlos gehen lassen. Selbst nicht im Fieber. Nimm dich zusammen.«

Fast mechanisch versuchte Jonas zu gehorchen. Er atmete mühsam.

Erik hatte sich auf die Kante des Bettes gesetzt, ohne seine Hände los zu lassen.

»Lege dich nieder. Ganz ruhig. Unterdrücke die Unruhe. Komm, mein Junge! strammer! Und nun höre mich: ich will dir helfen, wenn du mir folgst, aber anders als du denkst. Von Ruth mußt du dich jetzt trennen. Wir alle müssen es. Denn morgen schon reist sie fort, und bis dahin wirst du nicht aufstehen dürfen.«

Jonas fuhr empor.

»Papa! das muß ich! ich springe aus dem Bett! Ihr haltet mich nicht! Ich muß Ruth küssen, -- ich muß sie küssen, -- wenn sie geht!«

»Mit einem kranken, entzündeten Hals und Fieber wirst du Ruth nicht küssen wollen, hoffe ich,« unterbrach ihn Erik in einem Ton, der jede Widerrede abschnitt; »und du wirst es nicht nur unterlassen, sondern auch alles thun, was ich von dir verlange. Dich vollkommen beherrschen, wenn sie von dir Abschied nimmt. Mit keinem Wort, keiner Heftigkeit, keinem einzigen klagenden Ton es ihr noch erschweren. Alle Aufregung mit festem Willen niederzwingen. Das alles wirst du thun. Ich muß mich unbedingt auf dich verlassen können, wenn ich sie zu dir hereinführen soll. -- Kann ich es?«

»Ja!« stieß Jonas hervor, während ihm die Lippen noch zitterten. Er konnte nicht an gegen diesen Willen, der den seinen in Bann hielt.

»Gut. Und nun will ich dir einen helfenden Trost geben für deinen ersten großen Schmerz,« sagte Erik mit so weicher Stimme, daß es Jonas war, als spräche er mit den Lauten seiner Mutter zu ihm, »wenn Ruth von dir gegangen ist, blicke nicht zurück auf sie, sondern vorwärts in dein Leben; sorge dafür, daß du dich tüchtig entwickelst, arbeite daran, daß du bald ein ganzer Mann wirst, -- damit du ihr einst ein ganzer Freund sein kannst, wenn sie deiner bedarf. So kommst du, in allem was du thust, zu ihr zurück, -- ihr nahe. Dulde es nicht, daß sie dich so ganz überflügelt und dich einst weit -- weit hinter sich zurückläßt! Jetzt kannst du zeigen, was du wert bist, -- und ob du's wert warst, Ruth gehabt zu haben.«

Jonas lag ganz still und lauschte.

»Ja!« sagte er begeistert, »das will ich! ach, Papa, das will ich!«

Und er hob den Kopf und küßte den Vater. Erik hielt seinen Kopf einen Augenblick lang an sich.

»Wir werden ~nie mehr~ hiervon miteinander sprechen,« sagte er leise, -- »nie mehr. Aber vergiß es nicht. Zwinge deine Gedanken auf die Arbeit, auf das, was vor dir liegt. Suche dich mit mehr Festigkeit zu beherrschen. Ich werde darauf achten und dir nichts durchgehen lassen. Streng mit dir sein müssen, mein Junge. Mache es mir nicht schwer.«

»Papa,« versetzte Jonas so zutraulich, wie er sonst nur mit Klare-Bel zu sprechen verstand, »ich will mich nie wieder vor dir fürchten. Sei so streng du willst gegen mich. Du hilfst mir ja damit, nicht wahr? Tüchtig zu werden. So fest und tüchtig wie kein andrer. Ausstechen muß ich jeden andern! Hilf mir schnell, ein ganzer Mann zu werden! -- Ein Mann für -- für -- ich meine: ein Freund für Ruth.«

Am liebsten hätte er sich im Bett aufgesetzt und geplaudert; Erik mußte ihm das Sprechen verbieten und das Zimmer verlassen. Nun schwieg er; er lag zufrieden im Bett und dachte angestrengt an die Zukunft.

Erik war außer stande, sich wieder schlafen zu legen; er kleidete sich vollständig an. Er fühlte sich frei; wie erfrischt von einem langen, gesunden Schlaf, wie gekühlt und gestählt durch ein erquickendes Bad. Die ganze schwüle Beklommenheit vom Nachmittag und Abend, die noch auf seinen Träumen gelastet hatte, war verflogen. In der Einwirkung auf einen andern, dessen Unruhe er bezwang, dessen innerste, widerstrebende Gedanken er bestimmte, -- im kurzen Kampf mit dem Knaben, der zugleich sich gegen ihn auflehnte und ihm vertraute, hatte er sich selbst zurückgefunden. Seine Kraft geweckt und gesammelt. Er wußte recht wohl, wie es damit stand: wenn er sich am schwächsten fühlte, dann erstarkte er an der Kunst, andre in überlegener Behandlung zur Stärke zu veranlassen; an der gehobenen und mutigen Stimmung, die er von ihnen forderte und in ihnen hervorrief, -- an seinen eigenen überzeugten, überredenden Worten kletterte er selbst zu neuem Mute, neuer Zuversicht empor, wie an einer langen Leiter, die sich manchmal mitten aus seiner eigenen Verzagtheit erhob, aber bis ans Unbegrenzte zu reichen schien, -- bis an ein unbegrenztes Selbstvertrauen.

Viele tausend solcher Leitern, festgehalten von den Händen einer Menschenmenge, die ihn umdrängte, die an ihn glaubte, die auf ihn angewiesen war, -- und er hätte einen Himmel auf Erden erstiegen.

Nur kein Zusammenbrechen der festesten dieser Stützen! denn Stützen waren es, -- wie sehr auch er selbst als der Stützende dabei erschien. Niemand ist absolut stark.

Erik wußte recht wohl, wo seine Gefahr lag, wo auch in ihm der Schwächling steckte: da, wo er sich allein überlassen blieb.

Draußen herrschte noch dunkle Nacht. Es schlug drei Uhr.

Erik litt es nicht im engen, warmen Zimmer. Er öffnete leise die Hausthür und trat hinaus.

Die Finsternis war so dicht, daß er nur langsam der Tiefe des Gartens zugehen konnte. Er empfand den aufsteigenden Nebel, ohne ihn zu sehen. Das knisternde Rauschen der Birkenwipfel belehrte ihn über die Nähe des kleinen Gehölzes. Darüber glänzte am verhängten Himmel hie und da ein verlorener Stern. Das letzte Mondviertel, der schmale, blasse Vorläufer der Morgenröte, war noch nicht sichtbar.

Unweit der Bänke am Gehölz blieb Erik lauschend stehen. Er vernahm absolut nichts als das leise Rauschen der Blätter. Aber er fühlte, daß er nicht allein sei.

»Ruth!« murmelte er unwillkürlich.

»Ja! was soll ich?« fragte sie schüchtern.

Mit einem Schritt stand er neben der Bank; er tastete nach ihr.

»Was du sollst?! Im Bett sein!«

Er riß seine Joppe von den Schultern und warf sie ihr um.

»Was thust du hier mitten in der Nacht? Weißt du nicht, daß Jonas sich in dieser gefährlichen, kalten Feuchtigkeit das Fieber geholt hat?«

»Ja, ich weiß es. Aber mir schadet das nichts,« versetzte sie zaghaft, »das Fieber thut so gut; ich kenne es gut: da liegt man im Traum und hört auf zu denken. Und da dachte ich, ich könnte es auch so gut haben.«

Jetzt fühlte sie seine Hand, die sich fest um ihr Handgelenk legte.

»Was sagst du da?« fragte er ganz langsam, »du ~suchtest~ das Fieber?«

»Nein! nein!« rief sie flehentlich, »ich will es ja nur ein wenig, -- ein klein wenig nur, -- nicht so, daß es die Abreise hindern sollte! Ganz gewiß nicht!«

Ein Laut brach von seinen Lippen, wie wenn er verwundet würde. Sie konnte hören, wie seine Zähne leise übereinanderknirschten.

Er beugte sich über sie.

»Und das -- das glaubtest du zu dürfen,« sagte er matt.

»Ja, ich durfte es; denn ich will ja thun, was ich versprochen habe. Bin nicht ungehorsam. Nur so ganz allein bin ich. Niemand, der nur ein bißchen hilft. Da sollte das Fieber mir helfen. Ich darf thun, was ich will, -- wenn es nichts aufschiebt,« versetzte sie finster.

»So. Und wenn du nur rechtzeitig fortgekommen bist, meinst du, -- dann könntest du thun, was du willst? Auch vielleicht dich irgendwo hinsetzen und krank werden, wenn dir das ›hilft‹? Du irrst dich, mein Kind. Ich lasse dich nicht los, indem ich dich fortlasse. Und aus der Ferne sollst du mir doppelt gehorchen. Dein Versprechen geht auf dein ganzes Leben. Du bist mein. -- Bist du es?«

»Ja!« rief sie inbrünstig.

»Steh auf und geh hinauf.«

»Ich kann es nicht so, -- ich muß erst wissen, -- wann reise ich?«

»Ich werde es dir morgen sagen. Heute nacht nicht. Du sollst dich hinlegen und zu schlafen versuchen. An nichts denken als daran, daß du schlafen sollst. Wirst du es?«

Sie war schon aufgestanden.

»Ja!« murmelte sie, »morgen! Ich muß morgen fragen, was ich will.«

»Das sollst du.«

Er gab ihr die Hand.

»Geh voraus. Gehe nur. Ich folge schon. Warte im Hause nicht auf mich.«

»Gute Nacht!« sagte sie gehorsam und ging.

»Mein Liebling! gute Nacht!« rief er ihr nach.

Und im Klang seiner Stimme lagen alle die Liebkosungen, nach denen sie den ganzen Tag, die ganze Nacht gehungert hatte.

»Verzeih mir! Liebling,« sagte er reuig vor sich hin, während er ihr langsam folgte. Allein gelassen hatte er sie, allein stehen lassen in dem Augenblick, wo sie seine ganze Kraft und Liebe erwartete und ihrer bedurfte. Weil er sich selbst nicht traute, nicht vertraute, -- aus Furcht vor seinen Sinnen, -- und vor diesem unwissenden Kindersinn, der ihm mit einem Lächeln entgegenkam.

Das war feige gewesen. Nicht durfte er aus solchen feigen Gründen in letzter Stunde seine Hand zurückziehen, nach der sie sehnsüchtig und gläubig griff, als nach der Hand des einzigen Menschen, den für sie die Erde trug. Nicht überlegen, nicht geizen, nicht einschränken das, was er ihr gab, und wonach es sie mit einer Inbrunst verlangte, -- mit einer Zärtlichkeit, wie sie auf der ganzen Welt nur das einsame, das nie geliebkoste Kind kennt.

Aus einer unendlichen Fülle heraus sollte noch einmal seine Liebe sie umhüllen, sie umgeben, weich und schützend wie Mutterliebe, -- aus einer so reichen, so kraftsichern Fülle heraus, daß er sich aller Bedenken entschlagen konnte, -- daß er sein Liebstes nur noch wie auf starken Armen hob und trug, -- es einem schlummernden Kinde gleich in einem letzten Traum hinübertrug in die fremde, die kältere Welt. --

Der Hausflur war schwach erhellt von dem Licht, das an der offenen Thür zu Eriks Zimmer stand. Ruth hing die Joppe über den Thürgriff, und ohne sich nach Erik umzusehen stieg sie hinauf.

Er löschte das im Luftzuge flackernde, tropfende Licht und warf sich ausgestreckt auf den Lederdiwan in seinem Arbeitszimmer, froh des Dunkels, der Einsamkeit.

Seit der Stunde seiner Rückkunft gestern verlangte ihn unbewußt nach dieser Stille und Einsamkeit.

In dem Augenblick, wo er gestern aus dem Flur zu seiner Frau hineintrat, in dem Augenblick, wo Ruth an seiner Brust lag, und Bels Stimme ihn rief, war etwas Sonderbares in ihm vorgegangen. Sie rief: »Erik, bist du wieder da?« -- Aber ihn durchgellte es wie: »Erik, gehst du fort von mir?«

Und als er sie wiedersah, sie daliegen sah in dem Zimmer, das er so gut kannte, genau so wie zwei Tage vorher, da kam es ihm vor, als läge eine lange, lange -- jahrelange Reise dazwischen, während der er seine Frau nicht gesehen, nicht mit sich genommen, -- ja, vergessen hatte. Es war fast wie ein Moment der Geistesstörung gewesen.

Und die Erregung, in der alle seine Nerven noch zitterten, ließ keine Selbstbesinnung zu.

Aber jetzt -- jetzt stellte er sich wieder dahin, auf die nämliche Stelle, Bel gegenüber und ihrer fragenden Stimme, und jetzt antwortete er ihr: »Es ist eine lange, lange Reise gewesen. Ich ~habe~ dich nicht wiedergesehen all diese Zeit hindurch, -- dahin nicht mehr gesehen, wo du bist: dich vergessen.

Nicht zufällig, nicht unabsichtlich, nicht im Rausch des Augenblicks. Nein, bewußt und gewollt. Mit allen Sinnen und Gedanken wollte ich nur ~einen~ Punkt vor Augen haben, ihn durchschauen, durchdringen, -- in eine verhüllte Zukunft schauen und dringen. Unbeirrt von allem, was hindert und bindet. Frei, wie einer, der alles hinter sich geworfen hat, und dasteht wie ein Bettler oder wie ein König, wollte ich meine Hände aufheben zu meinem Glück.

Dann -- einst -- ist es an der Zeit, zurückzukehren zu den Fragen und Forderungen, den Pflichten und Fesseln des täglichen Lebens, um sich mit ihnen auseinanderzusetzen. Zu dir zurückzukehren. Zum Kampf. Zum Kampf um mein Glück.«

Erik hatte die letzten Worte fast laut gemurmelt: »Kampf -- -- -- Glück.«

Er öffnete, wie erwachend, die Augen.

Es war hell um ihn. Die Nacht vorbei. Glutrot stand der Himmel, wie in Flammen.

Hinter dem Gehölz ging die Sonne auf. Purpurn, strahlenlos wie ein ungeheurer Mond leuchtete sie durch den Morgennebel. Und purpurner Glanz auf den Fenstern, auf dem Fußboden.

Noch war im Hause niemand zu hören. Nur die Schwarzdrosseln schwatzten vor dem nahegelegenen Küchenfenster und unterhielten sich darüber, ob Gonne ihnen wohl bald, beim Zubereiten des ersten Frühstücks, ein paar Krumen zuwerfen werde?

Erik stand auf, stand still angesichts der Morgenherrlichkeit.

Er hatte Bel geliebt, -- so sehr, wie, nach seiner Meinung, der Mann bisher das Weib überhaupt lieben kann: nicht nur mit der Habgier der Sinne, nicht nur zu einem flüchtigen Liebesbündnis, das zufällig »Ehe« hieß, sondern zu einem wirklichen Lebensbündnis, das kein Staat, kein Priester, das nur der eigene, bewußte Wille besiegelt. Es war gewesen, wie er damals, im scherzenden Gespräche über die Ehe, zu Warwara gesagt: kein Pflichtbewußtsein, sondern das dauernde Glücksbewußtsein, seinem Weibe, auch nach dem Schwinden der Sinnenliebe, alles in allem zu sein. Daran hatten weder Krankenlager noch Altern, weder Lebensenttäuschungen noch Liebesversuchungen jemals das Geringste zu ändern vermocht.

Wenn er ihr je untreu geworden in einer heißen Aufwallung des begehrlichen Blutes, -- oder auch in einem bittern Rückblick auf die zerstörten, für sie hingegebenen Hoffnungen seiner Jugend, dann lehnte er sich gegen sich selbst auf mit Kraft und Härte. Niemals hätte er es doch zugegeben, daß irgend eine Gewalt stärker über ihn werden könne als sein Wille, seine Bürgschaft.

Und nun, wenn er alles sammelte, was er an Scham und Selbstvertrauen, an Stolz und Herzensgüte besaß, -- wenn er das alles sammelte und zusammenraffte, war es nicht genug, um Bel, die Wehrlose, gegen einen Kampf mit ihm zu schützen? Oder, wenn es denn in der Zukunft zu einem solchen Kampfe kam, gab es in seinem vergangenen Leben nichts, was stark genug, heilig genug, barmherzig genug war, um für Bel einzutreten und gegen ihn selbst zu siegen?

Erik schaute geradeaus, hinein in das rote Flammenmeer am Himmel. Er wollte, -- er mußte ehrlich sein.

Und er sagte sich: »Nein.« -- -- --

* * * * *

Auf der Terrasse wurde der Morgentisch gedeckt. Eriks Platz am Tisch blieb aber heute leer. Ganz früh hatte er sich Thee auf sein Zimmer bestellt, dann ging er zu Jonas hinein, um nach ihm zu sehen.

Gleich nach dem Frühstück ließ er Ruth zu sich bitten.

Als sie kam, streckte er die Hand nach ihr aus.

»Du schlechtes Mädel. Bist du gesund geblieben? Laß mich sehen.«

Sie nickte und trat zu ihm an den alten Ledersessel am Fenster.

Aufmerksam betrachtete er sie. Ihre Augen waren dunkel umschattet. Aber sie blickten sicher, -- fest. Es fiel ihm auf. Sie blickten beinahe kalt.

Er strich ihr das Haar aus dem blassen Gesicht zurück.

»Weißt du auch noch, daß hier dein alter Platz ist? Hier am Stuhl. Wo du zuerst herkamst. Wir haben ihn wohl fast vergessen, draußen im Garten und -- bei den andern. Monatelang. Aber der heutige Morgen gehört uns allein. Uns zusammen. Und den wolltest du krank zubringen.«

Sie antwortete nicht.

Ganz leise nur beugte sie gegen ihn den Kopf vor, so daß seine Hand durch die Haarwellen hindurchglitt, und schwieg still.

»Du bist ein dummes Kind,« sagte er, »sonst hättest du gewußt: wenn ich etwas von dir verlange, so sollst du es klar und still thun. Niemals in einem Fieberrausch. In keinem Sinn. Ich weiß, es ist tausendmal schwerer. Aber niemals sollst du es dir erleichtern. Durch nichts. Nur war ich dieses Mal selbst nicht ohne Schuld, Ruth. Ich selbst war wie krank, -- nicht wie ich sein sollte. Siehst du, nun beichte ich es dir auch. -- -- -- Ist es nun gut?«

Sie blickte ihn unverwandt an. Dann schüttelte sie den Kopf.

»Eins fehlt noch,« sagte sie.

Ihm kam ein Lächeln.

»Noch etwas? Was denn, mein anspruchsvolles Fürstenkind?«

»Darf ich nicht anspruchsvoll sein?«

»Das darfst du. Halte deine Hände offen, Liebling, und laß dich beschenken.«

Da glitt sie am Sessel nieder, auf ihren alten Platz zu seinen Knieen, und hob ihr Gesicht auf zu ihm, -- Trotz in den Augen.

»Ich meine kein Geschenk. Ein Recht.«

Erik stutzte.

Er schaute forschend in ihre Augen, mit dem fest auf ihn gerichteten rätselhaften Blick.

»Nimm dir dein Recht, Ruth,« sagte er einfach.

Sie flüsterte kaum hörbar: »Daß ich erfahre, ~warum~. Das plötzliche Fortmüssen, -- -- -- ~warum~?«

Er legte ihr die Hand über die Augen.

Eine lange Pause entstand.

»Du hattest vorhin ganz recht: eins fehlt noch,« antwortete er dann, »zwischen uns fehlt ~eins~. Weißt du, was es ist? Daß zwischen dir und mir ein zu großes Stück Menschenleben liegt, -- daß wir im Alter so weit voneinander entfernt sind. Denke nur: du und noch einmal du, das gibt immer noch nicht: ich. Auf eine so große Entfernung hin ist es bisweilen schwer, manches

miteinander zu teilen, -- mitzuteilen. Aber nun sieh das Wunder: dieser Mangel, diese Lücke und Leere zwischen dir und mir, -- ~sie~ eint uns gerade. Nur sie macht, daß ich dich leiten und dir befehlen kann. Sie macht, daß du da so vertrauensvoll knieen kannst, wie eben jetzt, und mit deinen trotzigen Augen zu mir aufschauen. Sie macht, daß ich den Weg besser kenne als du. Denn ich habe den halben Weg schon zurückgelegt. -- Oder könntest du das missen? möchtest du lieber, ich stände neben dir, von gleichem Wuchs wie du? noch suchend, irrend, eines Wegweisers bedürftig, wie du?«

»Nein!« sagte sie lebhaft, »das wäre wie zwei Kinder im Walde.«

»Dann nimm es hin, daß ich dir nicht antworte.«

Sie erwiderte nichts, aber er fühlte, wie ihr Herz wild zu schlagen begann. Sie gab nicht passiv nach, wie bis gestern noch. -- Sie war gestern irre geworden. --

Mit letzter Kraft mochte sie sich gegen ihn zusammengerafft, -- sich eingeredet haben, ihm gegenüber noch Kraft zu besitzen: Selbständigkeit. Im arglosen Schlummer erschüttert, mochten ihre Gefühle in Gärung gekommen sein, -- mochte eine Welt von unverstandenen Empfindungen in ihr ringen.

Die feine, ruhige, gerade Linie, in der sie sich vor Eriks Augen so kindlich weiter entwickelt hatte, wurde ihm undeutlich, wurde unruhig, -- sie schien sich zu biegen, -- eine Wendung zu machen: eine Wendung zu ihm hin -- oder von ihm fort.

Ueber Erik kam eine Spannung, die alle seine seelischen Fähigkeiten aufs äußerste schärfte, sein ganzes Wesen erwartungsvoll spannte, und jegliche sinnliche Erregung vollkommen niederhielt.

Er legte seinen Arm um Ruth und bog mit der Hand ihren Kopf zurück. Ihre Lippen zitterten.

»Sieh mir in die Augen, du Trotzkopf!« sagte er, »was hat sich da in dir geregt? Brich den letzten Trotz, -- denn es war einer. Laß mich ihn brechen. Es schadet nichts, wenn es einen Augenblick schmerzt. Gib nach, laß es geschehen. Wirf dein Recht von dir, mache dich rechtlos. Um Kinderrecht zu haben: um folgen zu dürfen, ohne zu fragen. Um zu gehen, ohne ein Warum.«

»Wann -- gehen?« fragte sie undeutlich.

Er drückte ihren Kopf an sich.

»Heute,« sagte er mit bedeckter Stimme, »jetzt. Jetzt gleich. Nein, nicht zusammenschrecken. Sei mein mutiges Kind. Wir haben nur noch diese Stunde, Ruth. Dann bringe ich dich in die Stadt. Zum Zuge, der ins Ausland fährt. Frau Römer wartet auf uns.«

Sie hatte sich in seine Arme geworfen. Sie umfaßte ihn so fest, als solle nichts sie von da wegreißen. Doch wußte er: sie widerstrebte nicht länger. Sie gab nach, willenlos.

Aber es war vielleicht nur die Angst des Abschiedes. Der Schreck davor, der sie überfiel. Gestern war sie doch irre geworden an ihm, -- und morgen? -- -- da besaß er keine Macht mehr über sie. Wußte nicht mehr, was in ihr vorging.

Er sagte sehr sanft: »Du gehst nicht fort, weil ich dir weh thun will, sondern weil ich dich lieb habe. So lieb, daß ich dir weh thun ~kann~. Gib dich dieser Liebe, Ruth, -- ohne Rückhalt, ohne Zweifel, -- gib dich ganz. Denke täglich, daß ich es zu dir sage, -- des Morgens mit deinem Erwachen, des Abends mit deinem Einschlummern: ~Ich hab' dich lieb.~«

Sie sah auf, ohne von ihm zu lassen, -- mit grenzenlosem Dank in den Augen sah sie auf. Ein kaum merkliches Lächeln spielte ihr um den Mund, -- ein wenig zaghaft noch.

»Da gehe ich ja nicht fort, -- da nehme ich Sie ja mit,« sagte sie, fast schelmisch.

Das Glück brach aus ihren Augen, -- ja, der Schalk.

Es berauschte ihn. Aber anders als gestern. Wohl hielt er sie im Arm, wohl kniete sie an seiner Brust, aber nicht seine Sinne wurden berauscht. Etwas unendlich viel Feineres, eine Wollust so fein, wie sie sich durch keine Sinne vermittelt, erfüllte ihn mit kraftvollem Genügen. Er konnte Ruth nicht unbedingter zu eigen nehmen, nicht stärker sich aneignen als in diesem Augenblick, wo er sie von sich löste, wo sie auf sein Geheiß von ihm ging, weil sie ihm lieb war.

Einigung und Trennung, selbstloses Verzichten und selbstsüchtiges Eingreifen, Schützen und Vergewaltigen, Dienen und Herrschen verschlangen sich ununterscheidbar in einem einzigen Gefühlsknoten, in einem einzigen Augenblick berauschenden

Erlebens.

»Ist es nun nicht gut, daß du mir gehorchen und vertrauen mußt? daß wir ~nicht~ sind wie ›zwei Kinder im Wald‹, die sich verlaufen? Für die es schlimm wäre, wollte eines das andre aus den Augen verlieren, -- verlassen. Mir kommst du aus den Augen, und doch nie von der Hand. Ich bin mit dir wie jemand, den du nicht neben dir stehen siehst, und doch um dich weißt -- über dir walten, wo du auch gehst und stehst. Wie jemand, den du nicht fragen kannst, und der zu manchem schweigt, -- der aber doch alles weiß, was dir not thut und gut thut wie --«

»Wie Gott,« sagte Ruth keck.

Das Wort lief wie ein Schauder über ihn hin.

Aus Gespensterfurcht?

Nein. Aber wohl, weil er ahnte, was mit diesem Wort in ihr selbst aufwachen mochte, an unbewußtem, ungeheurem Fordern und Bewundern und Erwarten.

Sie sagte es, gar nicht in Ekstase. Wie etwas Selbstverständliches. Wie ein Kind einen Kuß gibt.

Aber er ahnte: nie, noch nie war sie der Liebe, der vollen Liebe, so nah wie in diesem kindlichsten Bekenntnis, -- dem vermessensten.

Nein, keine Gespensterfurcht! vor nichts.

Und er küßte sie aufs Haar.

»Nicht wie Gott, Ruth. Und doch für dich: wie dein Gott.« --

Im Wohnzimmer war Klare-Bel damit beschäftigt, Ruths Koffer zu schließen und ihr eine kleine Reisetasche zu füllen. Gonne half, das Letzte zu ordnen und zu besorgen. Am Gartengitter draußen stand ein leichtes Fuhrwerk, eine ländliche »Karfaschka«, welche das Gepäck aufnehmen sollte. Erik wollte mit Ruth zu Fuß zum Bahnhof gehen.

Als das Gepäck aufgeladen wurde, kam er mit ihr aus seinem Arbeitszimmer heraus. Klare-Bel blickte erstaunt auf. Weder er noch Ruth machten ein trauriges Gesicht. Und doch wußte sie: erst jetzt, dort im Zimmer, hatte er es Ruth mitgeteilt.

»Wie er das nur zu stande gebracht hat? Er kann doch alles, was er will!« dachte sie bewundernd.

Das kleine Fuhrwerk rasselte davon, auf dem holperigen Landweg in beständiger Gefahr, eines seiner wackelnden Räder zu verlieren. Erik scherzte darüber, und Ruth harte ihre Schelmengrübchen in den Wangen.

Es war eine Heiterkeit, wie wenn an einem großen stummen, dunkeln Gewässer ein Sonnenrand aufblitzt und die Oberfläche mit glitzernden Perlen überblitzt.

Nur Gonne stand in der Küche und weinte mit einem mürrischen, verschämten Gesicht.

Einige Minuten lang konnte Ruth noch bei Jonas im Zimmer verweilen. Dann trat sie reisefertig, die graue Wollmütze auf dem Kopf, heraus.

Jonas horchte angestrengt. Er hörte sie über den Flur gehen, -- den letzten, grüßenden Zuruf seiner Mutter, -- die Thüren gingen, -- -- dann eine Minute der Pause, -- -- und nun fiel, mit einem schwachen Knarren, die Gartenpforte ins Schloß. -- -- --

Langsam, totenstill schlichen die Stunden hin, eine um die andre. Am frühen Nachmittag kehrte Erik aus der Stadt zurück.

Aber es blieb so still wie zuvor.

Jonas hielt es nicht länger im Bett aus; er stand auf, und seinen kalten Umschlag um den Hals, einen dicken Wollstrumpf darüber gebunden, stahl er sich auf seinen roten Pantoffeln in das Zimmer des Vaters.

Der Vater war nicht da.

Jonas setzte sich an den großen Schreibtisch. Er mußte machen, daß er fertig wurde, ehe der Vater ihn hier überraschte.

Und seine Feder kratzte über das Papier.

Er schrieb an Ruth:

»Süße, liebe Ruth!

Ich habe mich in Papas Zimmer hingesetzt an den Tisch, an dem du arbeitetest.

So ungeheuer gern wär' ich zum Bahnhof mitgegangen! Weinen wollte ich aber nicht, ich biß ins Kissen. Als aber in der Ferne der Zug lospfiff (vielleicht war es gar nicht dein Zug), da habe ich trotzdem ein bißchen geweint. Ich dachte: nun fährt sie fort.

Papa hat mir aber einen guten Rat gegeben. Ich will dir noch nicht sagen, was für einen. Ich will ihn lieber erst befolgen. Und solange ich ihn befolgen muß, was ziemlich lange dauern kann, werde ich dir nicht schreiben. Aber dann schreibe ich dir, daß du meine Frau werden mußt. Im Spiel hast du es niemals sein wollen, und das hat mich manchmal so schwer gekränkt. Aber das war dumm von mir. Denn erst muß ich ein ganzer Mann für dich geworden sein.

Darüber habe ich Papa noch nichts zu sagen gewagt.

Jetzt muß ich schließen. Aber ich mußte es dir gleich schreiben, damit du es weißt. Vergiß mich nur nicht, wenn du dort einen andern Jungen findest. Am Ende sogar einen fertigen Studenten? Dann würde ich mich ja hier so ganz umsonst anstrengen.

Aber vielleicht findest du keinen.

Ich küsse dich mit tausend Küssen.

Dein Freund, (dein zukünftiger Mann,) Jonas.

+Pst. Scr.+: Ich weiß nicht, wo Papa jetzt ist, ich bin heimlich auf. Sonst würde er dich sicher grüßen lassen.«

* * * * *

Erik war oben in der leeren kleinen Giebelstube.

Er stand am Fenster und weinte.

V.

Unflüggem Vöglein gleich, dem bangt, Wo's flatternd eine Zuflucht fände, So bin ich, flüchtend nur, gelangt, Ein armes Kind, in deine Hände.

Kam scheinbar wohl in trotz'gem Sinn, -- Doch nur von Einsamkeit getrieben, und kniete schweigend bei dir hin, und wollte nichts, als Etwas lieben.

Und wollte nichts, als, kurze Zeit, Gleich einem Kind mich wieder wissen, Nichts, als ein wenig Zärtlichkeit Ganz scheu, von ferne, mitgenießen.

Nichts, als von kindlich tiefer Qual Auf einen Augenblick nur rasten, Nichts, als die junge Brust einmal In heißer Hingebung entlasten.

Wie ward mir wohl, da ich dich fand, Als müßte jeder Wunsch sich stillen, Seitdem du mich, mit sanfter Hand, Geborgen ganz in deinem Willen.

Als würde plötzlich alles klar, Als müßten alle Wirren weichen, Seit über das verwehte Haar Mir deine lieben Hände streichen.

Bis daß ein jeder Schmerz hinfort Versank vor zaubermächt'gem Troste, Seit, mit dem ersten Liebeswort, Dein Blick mich zwang und mich liebkoste;

Bis ganz die Welt um uns versank, -- Und nichts von allem mehr geblieben, Als nur ein grenzenloser Dank, -- Und nur ein grenzenloses Lieben.

Ruth hatte das nicht gedichtet. Erik hatte es gedichtet. Aber Ruth hatte es gestammelt. Ungezähltemal. Vielleicht auch in ungezählten Versen.

Er wußte es nicht. Aber oben in der Giebelstube, unter fortgeworfenen Papieren und verwelkten Blumen, hatte das durchgerissene Blatt mit den gestammelten Versen gelegen.

Und seitdem dichtete er diese Verse, er sah vor sich hin und dichtete an ihnen.

Ruth hatte sie nicht gedichtet. Erik hatte es gethan.

Aber so, -- so in jedem Worte würde sie sie gedichtet haben, -- ein wenig später, -- im Rückblick.

* * * * *

Sie saßen alle zusammen.

Klare-Bel im Hintergrunde der Wohnstube, in einem großen, bequemen Lehnstuhl. Jonas am Eßtisch: er hatte die Lampe dicht herangerückt, um besser sehen zu können, was er in sein Schulheft schrieb. Erik am Kamin, in welchem mächtige Holzkloben brannten; von Zeit zu Zeit bückte er sich und warf aus einem blankgeputzten Kohlenbehälter, der mit Tannenzapfen gefüllt war, ein paar von den braunen, herzigen Zapfen in die Glut.

Das Zimmer hatte ein ganz winterliches Aussehen bekommen. An Stelle der leichten Sommergardinen schwere, schützende Fenstervorhänge, am Kamin zwei Sessel aus der Stadtwohnung, unter denen ein mächtiger Bär seine Tatzen vorstreckte.

Schon im Anfang des russischen März, noch ehe der Winter zu Ende ging, war dieses Jahr die Uebersiedelung vor sich gegangen. Klare-Bels wegen. Hinter ihr lag der Leidensweg eines halben Jahres, der sie langsam zur Genesung führte.

In der Ecke lehnten zwei starke Stöcke mit Krückgriffen. An diesen Stöcken mußte sie täglich einige Schritte thun. »Laufen lernen,« wie Jonas lachend sagte, der ihr am liebsten die Stöcke ersetzte. Und diese Schritte sollte sie in frischer Luft thun.

Sie saßen alle zusammen und schwiegen zusammen. Klare-Bel saß in halb liegender Stellung und sann vor sich hin; die Handarbeit, die sie vorgehabt, entglitt ihren Händen. Sie fühlte sich müde von ihren wenigen Schritten.

Jonas, der war wie verrannt in seine Arbeit. Mit den schmalen Schultern, lang aufgeschossen, ein wenig weichen, blonden Flaum an Kinn und Lippe, bückte er sich über die Bücher. Der Sicherheit halber hatte er auch noch in jedes Ohr einen Finger gesteckt. Das war unnötig.

Und Erik blickte in die Glut -- --

»Bis ganz die Welt um uns versank --«

Gonne war es, die endlich die Stille unterbrach. Sie brachte den Abendthee herein. Klare-Bel ließ sich hinter den Samowar rücken: ihre täglich neu genossene Freude, wenigstens in solchen kleinen Dingen wieder Hausfrau zu sein.

»Heute warst du gewiß froh, Erik, ein so langer Brief von Ruth,« bemerkte sie dabei, »man muß sagen: sie schreibt treulich, -- regelmäßig. Aber manchmal einen Zettel, manchmal ein Buch!«

»Ich möchte wissen, warum du ihr noch nie geschrieben hast, Jonas?« fragte der Vater, »sie will oft von dir wissen.«

Jonas wurde sehr rot.

»Wovon soll man sich denn schreiben? Ich habe genug zu thun,« murmelte er über seinem Theeglas.

»Für so junge Menschen ist das Briefeschreiben auch nichts,« meinte Klare-Bel, »Ruth ist doch sicherlich begabt, nicht wahr? Und sind ihre Briefe nicht ganz entsetzlich nüchtern, Erik?«

»Nun ja. Wenn sie nicht etwas zu erzählen oder zu beschreiben hat.«

»Beschreiben? was denn? wie ein Berg aussieht, oder was für Wetter es ist, -- ein Schneetreiben im Winter, kann sie das nicht seitenlang erzählen? Aber ich finde, dabei erfährt man recht wenig von ihr selbst.«

Erik schwieg. Er fand es auch. Dies Entzücken an der Schilderung, selbst des geringsten, die Hingebung in der Wiedergabe dessen, was sie umgab, und was unmittelbar von ihr aufgenommen wurde, -- das alles lag neben einer spröden Wortkargheit, wo es ihre Gefühle betraf. Es war nicht Verschlossenheit, -- es war Haß gegen das Wort, das ungenügende. Schlechte Verse kritzeln, singen, stammeln, die Augen aufheben, -- ehe er das nicht wiedergesehen, nicht wiedergehört, war Ruth für ihn wie begraben.

Und wieder schwiegen sie.

Der Theetisch wurde abgeräumt. Nur eine Fruchtschale mit Aepfeln blieb darauf stehen. Jonas machte Miene, seine Bücher und Hefte wieder auszubreiten.

Erik hinderte ihn daran.

»Genug!« sagte er, »es ist ganz unmöglich, daß du mit deinen Schularbeiten noch nicht fertig sein solltest.«

»Ich bin es ja auch, Papa. Aber ich wollte jetzt abends noch Russisch treiben. Einer von den Jungens hilft mir in der Freistunde darin.«

»Ich sehe nicht ein, zu welchem Zweck? Schon im Herbst gehst du ins Ausland. Du wirst ja nicht hier studieren. Wozu also?«

»Es ist sehr nützlich, Papa. In Deutschland kann man jetzt mit russischen Stunden Geld verdienen.«

Erik war unangenehm berührt. »Geld? Mit Stundengeben? Ueberlaß mir das doch.«

»Erlaube es mir, bitte. Thue ich nicht genug für die Schule?«

»Ja, aber du bist ein entsetzlicher Stubenhocker geworden, Jonas! Bleibst mir zu schmalbrüstig, mein Junge. Flaum am Kinn, aber keine Kraft in den Knochen. Nicht genug.«

»Gesundheit ist der Güter höchstes nicht,« behauptete Jonas mit einem Ernst, der ihm drollig genug stand.

»Aber der Uebel größtes ist die Schuld, sie verscherzt zu haben,« ergänzte Erik und fuhr ihm liebkosend über den Kopf; »wenn du öfters mit solchen Citaten kommst, dann werde ich dich noch ganz von den leidigen Büchern fortnehmen. Zu einem Bauern in die Lehre.«

Damit ging er hinüber in sein Arbeitszimmer.

Ein Stoß Schulhefte mit blauen Deckeln lag schon bereit. Auch allerlei andres, das drängte.

Ihn drängte es nicht. Er schob es zurück.

Darunter lagen Ruths alte Hefte, auch neue Arbeiten; sie schickte sie ihm alle. Ihren Studiengang leitete er vollkommen. Aber alles das war immer noch nicht »Ruth«.

Er nahm eine Mappe vom Schreibtisch, in der sämtliche Briefe aus Heidelberg lagen, vom vorigen August bis zum heutigen April.

Anfangs lauter Briefe von Frau Römer. Ruth konnte nicht schreiben, sie lag im Fieber. Ein schleichendes Fieber, fürchteten sie. Erik war zur Abreise vollständig fertig gewesen, er depeschierte bereits seine Ankunft.

Da traf ein Telegramm ein, das ihn zurückhielt. Drei Tage später ein kurzer Brief von Frau Römer:

»Ihre Anwesenheit ist nicht erwünscht. Die Trennung würde dasselbe noch einmal ergeben. Ruth muß es lernen, ohne Sie zu leben. Daher dürfen Sie unter keinen Umständen herkommen. Mein Mann meint es als Arzt, ich meine es aber auch -- als Frau. Ich habe Ruth lieb wie mein Kind; wollen Sie mir helfen, wie eine Mutter über ihr zu wachen, so entfernen Sie auf immer aus Ihren Briefen alles, -- auch das Geringste, was Sehnsucht wecken könnte.«

Nach einer Woche schrieb Frau Römer:

»Mit unsrer Ruth geht es besser. Aber gestern hat sie uns sehr erschreckt. In ihrem Zimmer steht mein Lehnsessel, mit braunem Leder bezogen; sie wollte ihn durchaus haben, als sie ihn bei mir sah, und sagte dabei bedauernd: ›Wie schade, daß er nicht grün ist!‹

Diesen Sessel hatte sie gestern nacht mitten ins Zimmer, ihrem Bett gegenüber, gerückt. Als mein Mann noch einmal leise hereintrat, um nach ihr zu sehen, sieht er im Schein der kleinen Nachtlampe Ruth aufrecht im Bett, -- den Oberkörper weit vorgebeugt, die Augen starr auf den Sessel geheftet, das Gesicht verzückt.

Als sie meinen Mann sah, fiel sie in die Kissen zurück. ›Ach, -- nun ist er fort!‹ sagte sie traurig. Sie war in einer halben Ohnmacht, am ganzen Körper kalt.

Wir haben den Lehnstuhl aus ihrem Zimmer entfernen müssen. Mit den andern Stühlen ›geht es nicht‹, versichert sie.

In aufrichtiger Freundschaft

Irene Römer.«

Bald darauf kam der erste, noch mit Bleistift aus dem Bett gekritzelte Zettel von Ruth selbst. Wenige Zeilen nur, darunter ein Postskriptum:

»Ich glaube, daß die Menschen zaubern könnten, wenn sie wollten.«

In der Mappe befand sich neben diesem kleinen Zettel ein Schreiben von Eriks Hand, -- ein vollständiges Briefkonzept, welches anfing:

»Mein Herzenskind!

Außer den bekannten zehn Geboten gibt es noch ein elftes, speziell für Dich: ›Du sollst nicht zaubern.‹

In ururalten Zeiten nahmen die Menschen, wenn ihre Götter die Wünsche einzelner nicht erfüllten, mitunter ihre Zuflucht zu fremden und bösen Geistern, die sich durch Zauberkunst und Zauberformeln beschwören ließen. Das mögen die Menschen aus zweierlei Ursachen gethan haben: aus Kleinmut oder Hochmut; aus dem mangelnden Glauben, daß im Willen ihrer Götter auch wirklich eine weise, gute Macht über ihnen waltet, -- oder aus dem Trotz, der es müde geworden ist, zu gehorchen und zu vertrauen.

Du machst es doch nicht ebenso, -- gleichviel aus welchem dieser beiden Gründe? Nimmst Dir doch nicht hinter dem Rücken und aus eigener Machtvollkommenheit, was Dir vorenthalten bleiben soll? Rufst doch nicht, wie damals, in der letzten Nacht, einen fremden, bösen Geist, das Fieber, um Dir zu helfen und Dich in eine Wirklichkeit zu entführen, die keine ist?

Du sollst nicht zaubern. Sollst Dich an die Wirklichkeit hingeben, die um Dich ist, -- ganz, voll Glauben und voll Vertrauen, daß Du in ihr zu Hause bist --«

Hier brach das Briefkonzept ab; die nächsten Zeilen waren ausgestrichen, -- wiederholt, und wieder ausgestrichen. Sie waren ihm sichtlich schwer von der Hand gegangen.

Aber die Konzepte mehrten sich; hinter jedem Briefe Ruths folgte eines; Erik blätterte sie ungeduldig beiseite: ~daß~ sie da lagen, das besagte genug.

Sein Blick verweilte nur länger, wenn er wieder auf die feine, charakteristische Handschrift Frau Römers traf. Er konnte das Gefühl nie ganz los werden, als ob er mit ihr -- oder sie mit ihm? -- in einem geheimen, unbewußten Kampf stände; und doch erquickten ihn diese Briefe. Wenn sie wider Wissen und Willen ein Feind war, so war's ein herrlicher. Einer, wie man ihn sich wünschen soll, um sich mit ihm zu messen.

Um diese Frau wehte es wie helle, reine Luft, -- man mußte sich wohl darin fühlen. Und jedes ihrer Worte ein so klarer Ausdruck dessen, was sie warm empfand. Während man las, glaubte man ihre Stimme zu vernehmen: eine heitere, entschlossene Stimme.

Schon wollte Erik die Mappe schließen und an ihren frühern Platz legen, als ihm noch ein Brief Ruths in die Augen fiel. Vor vielen Wochen geschrieben und durchaus nicht gefühlsmäßigern Inhaltes als die übrigen, -- auch, gleich den übrigen, ohne Anrede und ohne andern Abschluß als »Ruth«. Aber auf der letzten Seite, da hatte sie sich verschrieben: da stand einmal »Du«, anstatt »Sie«.

Sie hatte den kleinen Verräter energisch ausgestrichen und das ihm beigefügte Zeitwort umkonjugiert. Aber am Rande der Seite war's treuherzig bekannt: »Ich habe ›Du‹ gesagt, ich wollte aber ›Sie‹ sagen.«

Erik schaute nie in die Mappe hinein, ohne an dieser Stelle hängen zu bleiben, -- und er schaute oft hinein.

Diese eine Silbe war ihr einziger wirklicher Gruß an ihn. Mündlich würde sie sich schwerlich je versprochen haben. Sie bedurfte dessen nicht. Sie ~hatte~ »Du« zu ihm gesagt, an jedem Tage, in jeder Stunde fast, mit Blick und Ton und Miene. Jetzt erst ward es zum verständlichen Wortlaut, unwiderstehlich: ein Ersatz für alle wortlose Nähe.

Erik schob die Briefe von sich; er wollte arbeiten. Arbeiten, -- nur nicht dieses unnatürliche, vollständig entnervende Hinleben in Gefühlen und Gedanken, -- dieses unsichere Tasten ins Blaue, in die Ferne, mit dem Verzicht darauf, zu handeln. Wie leicht war dagegen selbst die Trennungszeit für ihn gewesen: innerste, angespannteste Aktivität bis zur letzten Sekunde, aufs höchste gesammelte und gesteigerte Kraft: für Ruth.

Nun der Rückschlag. Nachlassen, -- gehen lassen. Es machte ihn fast krank.

Und er arbeitete Stunde um Stunde, bis eines der blauen Schulhefte nach dem andern mit den notwendigen roten Tintenstrichen durchsetzt war.

Dann erst lehnte er sich müde in seinen Stuhl zurück. Und wieder las er, mit immer neuen Kommentierungen, an der einzigen Silbe »Du«. --

Der nächste Tag brachte draußen die erste echte Frühlingsstimmung. Ein tiefblauer Sonnenhimmel strahlte über den kahlen Bäumen. Noch zog sich am Rande der Kieswege, schmal und vergraut, eine durchlöcherte Schneekruste hin, aber aus dem toten Gras hoben sich schon frisch die saftgrünen Hälmchen, und an den Birkenzweigen hingen seit Wochen, geduldig wartend, längliche braune Knospenzipfel. Der Wiesengrund hinter dem Garten stand ganz unter Wasser und spiegelte blinkend Himmel und Sonne wieder; vereinzelte zersplitterte Eisschollen trieben darin umher.

Erik hatte, wie jetzt fast immer, den ganzen Tag in der Stadt zu thun; neben seinem Schulunterricht noch den freiwillig erteilten, den er, mit sich daran anschließenden Vorträgen, in diesem Winter durchführte: teils in seiner Stadtwohnung unter Beteiligung Erwachsener, teils in einem leerstehenden Klassenzimmer der Mädchenschule.

Diejenigen, die sich hier einfanden, gehörten ebenfalls der Schule nicht mehr an, oder doch fast nicht mehr. Man konnte es den Gesprächen entnehmen, mit denen sie ihn meistens erwarteten. Es wurde nicht mehr von Phantasieereignissen gesprochen, sondern von Bällen und Gesellschaften und von Anbetern, die wohl nicht mehr in der bloßen Einbildung existierten. Von Schulangelegenheiten niemals, wenn nicht etwas ganz Sensationelles vorfiel, wie heute morgen, wo ein kleines Mädchen beim Frühgebet im großen Schulsaal umgefallen und liegen geblieben war, -- ein Fall von Epilepsie. Es hieß, das bloße Ansehen wirke ansteckend, nichtsdestoweniger hatten die meisten, wie gebannt, auf die Zuckende hingestarrt, welche, Schaum an den Lippen, vor ihnen lag.

Mitten in das Gespräch darüber kam, als die Späteste, und mit einem unterdrückten Gähnen, die hübsche Wjera mit den kecken dunkeln Augen. Sie war seit der Zeit ihrer Backfischstreiche noch hübscher geworden.

»Bist du auch wieder da?« rief Eriks fleißigste Schülerin sie an, »ich möchte wissen, wozu? Ob es dir wohl angenehm ist, daß er immer nur Spott für dich hat?«

»Und Lob für dich; da ziehe ich mein Teil vor,« erwiderte sie mit Ueberzeugung; »laß ihn nur spotten, das thut ihm gut, er ist bei schlechter Laune. Glaubst du, daß dein Fleiß ihn beglückt, mein geliebtes Gänschen?«

»Mehr als fleißig sein kann niemand,« bemerkte eine, die in Erwartung des Kommenden auf dem Fensterbrett saß und häkelte.

Wjera lachte boshaft: »Nun, er könnte noch allerlei andres schmerzlich vermissen, -- zum Beispiel Verstand. -- -- Lieber Gott, was kann es nützen, sich so anzustrengen?«

»Warum bleibst du denn nicht weg? Du wolltest ja haben, was Ruth hatte, -- du am meisten.«

Wjera saß nachlässig hingegossen, die Arme längs der Banklehne ausgestreckt, und schielte seitwärts in den kleinen Handspiegel, den jemand in der Nähe des Fensters angebracht hatte, und der immer umstanden war.

»Ich glaube nicht daran, daß er mit uns so ist wie mit Ruth,« murmelte sie; »es wäre der reine Betrug. Entweder hat Ruth uns gefoppt, -- oder wir sind -- dumm. Glaubt ihr etwa, Ruth meinte ~das~, als sie so außer sich vor Entzücken sagten ›O -- -- dahinter gibt es das ganze Leben?‹ Wir stehen noch ~vor~ der Mauer, -- wie eine Hammelherde.«

»Na, so geh doch hinüber.«

»Ich werd' auch,« versetzte Wjera kurz, -- »noch heute. Wollt ihr? Mit ~einem~ Satz! Aber daß ihr nicht schreit! Ihr könnt ja nachspringen.«

Im Nu drängten sie sich um sie, brennend vor Neugier.

»Was wirst du thun?!«

Sie erwiderte nichts. Sie hob nur das Gesicht ihnen entgegen und spitzte den Mund ein wenig.

»Ein Kuß?!«

Sie schrieen jetzt schon.

Da trat Erik herein. Er bemerkte, daß sie zerstreut waren, beachtete es aber nicht. Wjera las vielleicht ganz richtig in seinen Augen: »Wie eine Hammelherde.« Er vermißte Ruth unter ihnen, nicht weil er sie liebte; er vermißte sie, weil sie ihn fortwährend angeregt, fortwährend seine Geistesgegenwart verlangt hatte. Für sie mußte er auf der Höhe seiner selbst stehen, um niemals fehlzugreifen.

Das war hier unnütz.

Nach kurzer Zeit erhob sich Wjera und ging, ein Blatt Rapier in der Hand, auf Erik zu.

»Sollte es möglich sein?« fragte er sarkastisch, indem er annahm, sie wolle ihm eine Arbeit vorlegen, »es wäre das erste Mal.«

Sie stieg die beiden Stufen zum Katheder hinauf und beugte sich zu ihm, -- so tief, daß er aufsah. Bei dieser Bewegung seines Kopfes berührten sich fast die beiden Gesichter.

Da durchgellte ein Schrei die Klasse, einstimmig. Sie hatten's nicht aushalten können.

Aber gleich darauf folgte ein zweiter, ganz anders im Ton: Wjera war, kaum daß der Schrei erscholl, hintenübergestürzt.

Erik selbst gingen Ursache und Wirkung durcheinander, ob der erste Schrei vorherging, ob er folgte, -- ob sie sich niedergebeugt, weil sie im Stürzen war. -- Er hatte auch vom Fall im Schulsaal gehört, und jetzt ergriff die Erinnerung daran die Mädchen mit kopflosem Entsetzen.

Die meisten sprangen auf, einige sprangen im plötzlichen Schreck auf die Bänke, -- auf das Fensterbrett.

Erik brach sich Bahn. Er hatte die wie leblos Daliegende auf seine Arme gehoben und trug sie hinaus.

Als er raschen Schrittes den Gang entlang dem nächsten leeren Zimmer zuging, kam Leben in sie. Der ganze weiche, geschmeidige Körper bewegte sich, als strebe er, erzitternd, sich an ihn zu schmiegen; ihr Atem flog; wie um sich zu halten, schlang sie den Arm um seinen Nacken, und jetzt -- jetzt fühlte sie deutlich, wie es ihn heiß überlief.

Blitzschnell, eh' er's nur gewahr wurde, hatte sie ihren Mund auf seine Lippen gedrückt.

Aber in der nächsten Sekunde fand sie sich schon auf ihre Füße gestellt -- hart, so plötzlich, daß sie fast zusammengestürzt wäre. Eine sinnlose Wut überfiel ihn. Wie ein Bild stand vor ihm der Augenblick, wo er Ruth, wie ein lebloses Kind, in seinen Armen auf ihr Bett getragen.

Er ergriff die verblüffte Spitzbübin beinahe brutal beim Handgelenk und zwang sie die wenigen Schritte bis an die hohe Flügelthür, die den Hallengang gegen das Treppenhaus hin abschloß. Er stieß die Thür auf.

»Hinaus. Ohne Wiederkehr,« sagte er kurz.

Sie errötete und erblaßte. Sie ging nur langsam hinunter, Stufe für Stufe, und hielt sich am Geländer. Was würden die andern in der Klasse wohl denken, wenn sie nie wieder kam? Daß er ihr über die Mauer geholfen habe? Ja, gründlich. Mit einem Satz.

Und das Schlimmste: sie hatte eine gehörige Beule weg, gerade vorn an der Stirn. --

Erik gab sich Mühe, bei der Rückkehr in seine Klasse, der Stimmung Herr zu werden, die ihn peinigte und niederschlug. Er hatte sich jedesmal gewundert, den bildhübschen Nichtsnutz mit unbegreiflicher Hartnäckigkeit noch auf ihrem Platz dasitzen zu sehen,

und dennoch fest entschlossen, nichts zu lernen. Er hatte sich auch ein wenig gefreut. Weil sie ein kluges Ding war, voll Mutterwitz und Phantasie. Er wußte jetzt, von was für einer Art von Phantasie.

Aber lag es nicht an ihm? War es nicht an ihm, allen diesen jungen Menschen unausweichlich die Richtung zu geben? Auswüchse auszuschneiden, Fehlendes zu ergänzen, Schlummerndes zu wecken? Er hatte sich seiner Aufgabe wohl mit seinem Willen hingegeben, aber nicht mit seinem Herzen. Und kein noch so guter Wille vermochte sein mächtigstes Erziehungsmittel zu ersetzen: das war die Frische und Fülle der Stimmung, deren immer bereites Interesse sich auch noch in das Geringste eingrub, suchend, lockend, verständnistief. Und er bedurfte dessen ganz besonders. Denn seine Vorzüge wie seine Schwächen als Lehrer bestanden darin, daß er seine Persönlichkeit und seinen Unterricht nicht zu trennen wußte; gelang es ihm nicht, sich selbst zu geben, so mißlang ihm alles. --

Am Thorweg des Schulgebäudes wartete Jonas auf den Vater. Sie fuhren zusammen nach Hause aufs Land.

Im Eisenbahnwagen sagte Jonas: »Mama spricht jetzt immer davon, daß sie bald verreisen muß. Sie kann doch nicht so früh im Jahr ins Bad reisen?«

»Ich weiß noch nicht. Vielleicht wird es wünschenswert sein. In Deutschland ist es ja nicht mehr so früh im Jahr. Dagegen spricht nur, daß ich sie jetzt noch nicht selbst hinbringen kann. Das müßtest du dann thun, Jonas. Und sie würde Gonne mitnehmen.«

»Wenn ich Medizin studieren werde,« bemerkte Jonas nach einer Pause, »dann wird es mir immer vor Augen stehen, das Wunderbare, daß es mit Mama besser geworden ist. Ich denke mir: Arzt zu sein, und ein einziger solcher Fall, -- das muß auf alle Lebenszeit einen glücklichen Menschen machen.«

»Du bist ein guter Kerl, Jonas. -- Ich hätte übrigens nicht gedacht, daß du speziell ›Medizin‹ wählen würdest. Ich dachte: Naturwissenschaften.«

»Ja, ich selbst auch, -- früher. Am liebsten Zoologie. Aber es ist eine so ungewisse Zukunft damit. Ein Arzt findet überall sein Brot.«

»Das ist richtig. Aber das allein Ausschlaggebende dürfte es nicht sein. Es kam immer noch auf die Stärke der besondern Neigung und Befähigung an. Wenigstens für dich. Das andre war dann meine Sache.«

»Ich möchte aber so früh als es geht unabhängig werden, Papa. Selbständig.«

»Ist es dir so unangenehm, dich von mir abhängig zu wissen, mein Junge? Es ist nur dein gutes Recht. Noch lange. Ich will nicht, daß dir deine Studien durch irgend etwas verkürzt oder eingeschränkt werden.«

Den Rest der Fahrt schwiegen sie. Jeder blickte, in seine eigenen Gedanken vertieft, zu einem andern Fenster hinaus.

Zu Hause, über dem Garten, dunkelte es schon. Aus dem Wohnzimmer blinkte Licht. Der späte Mittag, der jetzt in den Abend fiel, wartete auf sie.

Erik legte beim Eintreten eine Handvoll blaßblauer Fliederzweige auf den Tisch. Er hatte sie in einer Hülle von Seidenpapier mitgebracht.

»Aber, Erik!« sagte Klare-Bel vorwurfsvoll, während sie doch vor Freude errötete, »etwas so Kostbares und Ueberflüssiges! Im russischen April!«

»Ueberflüssig?« Er ordnete die langen Stiele geschickt in einem geschliffenen Kelchglas. »Der Frühling ist doch nicht überflüssig. Und ich meinte: in einem Landhause müßte er wenigstens drinnen sein, wenn er schon nicht draußen ist.«

Ihre Augen füllten sich langsam mit Thränen; sie schlug sie nieder, damit er es nicht sähe. Der Frühling ~war~ ja drinnen eingekehrt, ~ihr~ Frühling, auf den sie gewartet hatte, wie auf eine Lebenserneuerung gerade für Erik. Aber dieser Frühling war blumenlos und frostig geblieben.

Nein, das war ungerecht. Ungerecht gegen ihn, dem sie ihre Genesung dankte: abbittend blickte sie Erik verstohlen an. Aber ~das~ mußte sie ja sehen: er ertrug kaum die Trennung, -- die Trennung von Ruth. Solange Bel ihn glücklich gesehen, war sie arglos und sorglos geblieben. Jetzt aber lag es auf ihr, bei Tag und bei Nacht.

»Hast du Ruths gestrigen Brief schon beantwortet?« fragte sie nach einer Pause.

»Ja. Noch nicht völlig beendet,« erwiderte er.

Sie zog den Flieder zu sich heran und vergrub ihr Gesicht in den duftenden Dolden.

»Da war doch, -- ist der junge Russe noch immer da, den sie so gern haben?«

»Jurii? Ja. In den jetzt angehenden Ferien sollte er sogar, glaub' ich, eine kurze Zeit bei ihnen wohnen, -- draußen am Schloßberg. Sie wollten allerlei zusammen unternehmen. Römer hält viel von ihm.«

Eine kleine Pause entstand.

»Wie alt ist er eigentlich, Erik?«

»Ungefähr zweiundzwanzig Jahre, glaub' ich.«

»Und gänzlich unabhängig, nicht wahr? Es handelt sich für ihn nicht um ein Brotstudium?«

»Nein.«

Erik blickte auf, ein flüchtiges Lächeln um den Mund. Auf den jungen Russen eifersüchtig, -- nein, das war er unter keinen Umständen.

»Eine echt weibliche Kombination, Bel. Du dachtest schon an Brautkranz und Schleier, nicht wahr? Aber dafür, daß Ruth rasch mit ihm vertraut geworden ist, liegt ein andrer Grund vor: er ist ihr nicht fremd. Er kennt ihren Onkel hier. Hat einmal früher mit seinen Eltern dort verkehrt, -- mit ihr gespielt, als sie acht und dreizehn Jahre alt waren.«

Sie lehnte den Kopf zurück.

»Es ist nichts,« dachte sie, »es kann nicht sein. Sonst müßte -- ~müßte~ er eifersüchtig sein. Trotz seinem starken Selbstvertrauen. Jugend sucht Jugend.«

Nach einiger Zeit sagte sie bittend: »Erik! Du mußt nicht böse sein. Ich habe einen so großen Wunsch.«

»Einen so schlimmen, Bel? Nun, heraus mit ihm.«

»Ich wünsche so sehnlich, -- ich möchte so sehr gern, nur ein einziges Mal, -- lesen, was du an Ruth schreibst.«

Er antwortete nicht. Er stand auf und ging aus dem Zimmer. Gleich darauf kehrte er zurück, den fast beendeten Brief in der Hand.

»Du kannst es jedesmal lesen, Bel, wenn du willst.«

Ihre Augen strahlten ihn so dankbar und beglückt an, daß er den Blick nicht aushielt. Er sah hinweg.

Es war ihm eine Pein, sie dasitzen zu sehen, -- lesen zu sehen. Am liebsten wäre er hinausgegangen.

Er trat an das Fenster und schaute in die Dunkelheit.

Aber das Fensterglas höhnte ihn. Was es wiedergab, war noch einmal das Zimmer, mit der Lampe auf dem Tisch, den zarten Fliederzweigen und der lesenden Frau im Lehnstuhl.

Klare-Bel ließ den Brief sinken. Sie sah betroffen aus.

»Wie seltsam, Erik,« sagte sie, »-- ich kann mir gar nicht vorstellen, daß du so an Ruth schreibst.«

»Ich glaube ihr nicht anders zu schreiben, als ich zu ihr gesprochen habe,« entgegnete er.

»Es mag ja sein. Aber dann kam wohl noch allerlei hinzu, was nur im Mündlichen liegt. Dein ganzes Wesen kam hinzu. Du bist ja so jung und frisch im Wesen, Erik.«

»Nun, -- und?«

Er wandte sich um. Gewiß fand Ruth seine Briefe ebenso »entsetzlich nüchtern,« wie er die ihren. Nur aus einem andern Grunde: sie konnte nicht ihr Inneres aussprechen, -- und er durfte nicht.

»Ja, -- nun, -- ich weiß nicht, wie ich es beschreiben soll, Erik. Aber in dem Brief da bist du wie ein ehrwürdiger alter Mann, mit langem weißem Bart und Haar, -- ungefähr so, wie die Kinder sich den lieben Gott vorstehen.«

Es durchzuckte ihn. Er mußte an Ruths Wort denken: »Wie Gott.«

Eine Fülle widerstreitender Empfindungen wühlte es in ihm auf. Was für ihn wie für Ruth diesen Briefwechsel nüchtern machte, -- im lebhaftesten Plauderton noch kalt und stumm, -- das mochten wohl zwei ganz entgegengesetzte Gefühle beim Lesen der Briefe sein.

Für ihn war's ein Abzug am Vollen, Menschlichen ihrer Persönlichkeit, ihres innersten Wesens, das in Worten nur seine Oberfläche zu zeigen vermochte. Für ~sie~ war's vielleicht ein Zusatz zu seiner menschlichen Persönlichkeit, eine ~Verklärung~ derselben: er hatte ihr ja auch mündlich sein innerstes Wesen verschweigen müssen, und gerade das idealisierte sie sich nun vielleicht aus seinen geschriebenen Worten, -- »ungefähr so, wie die Kinder sich den lieben Gott vorstellen.«

Daher war ihm auch nie von selbst das Bedenken gekommen, sie könne an seinen Briefen ebensoviel auszusetzen haben, wie er an den ihren. Denn er hatte gefühlt: in seinen Briefen ergriff sie seine Hand und ging an derselben vertrauensvoll ihren Weg. Gehorsam -- froh. Denn sie litt doch nicht? Nein, das that sie gewiß nicht.

Man hatte sie dort mit einem Leben umgeben, das sie unausgesetzt anregen, bereichern, entwickeln mußte, -- sie beglücken und sie erfüllen. Und mit ihrer unbegrenzten Empfänglichkeit stand sie mitten in diesem Leben, -- wie mit weit ausgebreiteten Armen.

Nein, sie -- sie litt nicht.

Auch Klare-Bel war verstummt. Wieder hing jeder seinen eigenen Gedanken nach, und wieder wurde es heute ein schweigsames Abendessen. Wie sie da zu dreien bei einander saßen, eng zusammen, in herzlicher Neigung verbunden, blieben sie doch einander so weltenfern entrückt, daß keiner von ihnen teil hatte an der stummen Welt des andern.

Als nach dem Essen Erik sein Zimmer nicht wieder verließ, setzte Jonas, ohne Schularbeiten, sich zur Mutter.

»Wenn Papa nicht da ist, muß ich ihn ersetzen,« versicherte er, »kann ich dir nicht schon bald fast dasselbe sein wie Papa? Einen guten Kopf größer als du bin ich doch schon, meine kleine Mama.«

Sie sah ihn mit einem tiefen, stillen Blick an, den er nicht verstand. Dann streckte sie ihm über den Tisch ihre Hand hin.

»Mein lieber Junge. Ja, mir kannst du bald -- viel sein. Wirst du es auch nicht vergessen, später, über all dem Studieren? Du mußt mir viel -- viel Freude machen, Jonas.«

»Ich werde dir ganz ungeheuer viel Freude machen, Mama,« erklärte er treuherzig, »das werde ich ganz bestimmt. Denn ich werde etwas ganz Ausgezeichnetes werden. Das muß ich.«

»Freust du dich sehr auf das ungebundene, neue Leben draußen?«

»Auf draußen, -- ja. Aber das mit dem ungebundenen Leben finde ich gar nicht so schön. Ich finde es viel schöner so, wie Papa es gehabt hat.«

»Wie denn, mein Kind?«

»Nun, doch so ganz gebunden, Mama. Mit dir zusammen. Das kann ich mir nämlich so wunderschön ausmalen. Fast als ob --. Eine Studentenstube, -- ganz klein braucht sie ja nur für den Anfang zu sein, und an den Wänden Bücher, und auf dem Tisch eine Kochmaschine zum Selbstkochen. In der Ecke ein schönes Skelett und am Fenster viele Blumen. Da sitzt die Frau mit dem Nähzeug. Und bei den Büchern, da sitze ich, -- ich meine: sitzt Papa.«

»Ganz so war es wohl nicht. Nicht so eng. Für Blumen und Kochmaschinen und Nähzeug schwärmte Papa nicht sehr. Und wenn er bei den Büchern war, dann mußte er in seinem Zimmer allein sein. Da warst nur du bei mir. In einer kleinen Wiege.«

»Eine kleine Wiege?«

Jonas wurde ziemlich rot. An dieses Stück der Zimmereinrichtung hatte er noch gar nicht gedacht. Er sagte etwas befangen: »Nun ja. Aber wenn du auch nur nebenan gesessen hast, so war es doch ~das~, was ihn fleißig machte. Und eben das denke ich mir so herrlich beim Studieren, wenn man's für jemand thut, den man so über alles lieb hat.«

»Das sage du Papa lieber nicht. Das würde ihm vielleicht mißfallen. So hat er es mit seinen Studien und Plänen wohl nie gemeint. Er war so ganz anders, als du bist, Jonas. Aber unendlich gut und klug war er. Und als er anfangen mußte, sich ums Brot zu plagen, und es mich grämte, da lachte er mich so herzlich aus und sagte: ›Laß gut sein, Bel, ich hab' ein Mittel, ein Zaubermittel, um frisch zu bleiben, -- mag es noch so viel Plage geben, -- frisch für meine Ziele: das Mittel bist du, Bel‹. Ja, so sagte er.«

Jonas schwieg. Er wollte den Vater nicht vor seiner Mutter herabsetzen, aber in diesem Punkte fühlte er sich ihm weit überlegen.

»Man kann noch tausendmal mehr lieben!« dachte er im stillen.

Klare-Bels Gedanken aber träumten sich, schmerzlich und beglückt, in die Zeit ihrer Studentenehe zurück. Sie sah alles vor sich, als habe sie es eben erst verlassen, und durchwanderte jeden Winkel, der ihr Glück beherbergt hatte. Sie sah auch die Stube, wo er über seinen Arbeiten saß, und sie ihn leise, -- ganz leise mußte es sein, -- umsorgte. Aber gerade dieses Bild verwischte sich ihr, wurde undeutlich wie vor Thränen. An Eriks Stelle saß ein andrer, -- saß Jonas; -- und immer wieder, mit einem dumpfen Zukunftsgrauen, erblickte sie sich allein, -- allein mit dem Sohn.

Die Nacht lag Klare-Bel wach, und als sie gegen Morgen einschlummern wollte, schreckte der Gedanke sie auf, als müsse sie über irgend etwas angestrengt und mit Schmerzen nachgrübeln.

Am folgenden Tage fielen die Schulstunden aus; irgend einer der zahlreichen griechischen Kirchenheiligen wurde gefeiert. Erik setzte sich am Vormittag mit einigen Büchern und Papieren ins Wohnzimmer, wo, in der Nähe des Kaminfeuers, ein Schreibtisch für ihn improvisiert worden war. Draußen stöberte ein ganz feines Schneewetter aus ein paar finstern Wolken, hinter deren blau-schwarzem Rande die Aprilsonne neckend bereits wieder hervorlachte. Hell und dunkel glitt es über das Zimmer hin.

Klare-Bels Augen hingen mit einem wehmütigen Ausdruck am Arbeitenden. Heute morgen wollte sie ihn fragen. Sie hielt es nicht länger aus. Wie hatte sie nur denken können, seine Briefe würden ihn ihr verraten? Denn Ruth war ja noch so ganz unbewußt gewesen. Zu ihr konnte er nicht offen sprechen. Daher gerade der auffallend zurückhaltende Ton. Vor ihr verbarg er sich -- befangen und mühsam.

»Wo steckt Jonas eigentlich?« fragte Erik, über seine Ausarbeitungen gebeugt.

»Jonas ist nun doch wieder zur Stadt gefahren. Er wollte so gern seinen Freund besuchen.«

»Hoffentlich doch nicht, um wieder zu arbeiten, -- mit dem Freunde?«

»Vielleicht. Laß ihn, Erik. Ist er nicht ausgezeichnet geworden?«

»Ja. Höchstens zu ausgezeichnet. Er hat viel vor sich gebracht, das muß man dem Jungen lassen. Sowohl was seine Fähigkeiten wie seine Ausdauer betrifft, hat er meine Erwartungen im letzten Halbjahr weit übertroffen.«

»Nicht nur das. Er ist dabei so verständig geworden. Ihm steckt kein Unsinn im Kopf. Keine Kindereien.«

»Ja. Gerade das mißfällt mir. Dafür ist er zu jung. Wenn er nur nicht eng wird. Mit siebzehn Jahren muß man nicht Philister sein.«

»Ach, Erik, wenn er nur brav wird.«

»Das kann er immer noch. Zunächst soll sein Temperament heraus! Heidelberg wird ihm gut thun, denke ich, und Römers Einfluß. Man muß sorgen, daß er sich frei bewegen kann. Weder Zeit noch Geld darf ihm knapp zugemessen werden.«

»Wie gut er ist!« dachte Klare-Bel, »ja, in solchen Dingen ist er immer unendlich gut gewesen. Würde sich plagen für den Jungen, damit der lernen kann, zu genießen.«

Mehrere Minuten vergingen in Schweigen. Eriks Gedanken liefen voraus, dem Herbst entgegen, wo Jonas nach Heidelberg abging. Allerspätestens dann mußte er Ruth wiedersehen, sie sprechen. Vielleicht aber schon früher. Wenn Klare-Bel so ins Bad reiste, daß er sie mit Beginn der Sommerferien in Deutschland abholen konnte.

»Erik!« sagte eine Stimme neben ihm.

Er sah zerstreut auf. Seine Frau stand am Schreibtisch -- ohne ihre stützenden beiden Stöcke. Sie hatte sich selbständig erhoben und war durch das ganze Zimmer zu ihm hingegangen, -- allein.

Sie hatte es heimlich geübt, mehrere Tage.

Erik vermochte nicht gleich aus seinen Gedanken herauszukommen. Er blickte sie nur fragend an, ohne zu beachten, was ihn überraschen sollte.

Er bemerkte es nicht.

Auf Klare-Bels Lippen erstarb ein Lächeln.

»Ich wollte dir nur zeigen, was ich kann,« sagte sie, mit einer gewaltsamen Anstrengung, es unbefangen zu sagen.

Aber es mißlang. Sie erblaßte. Und plötzlich schwankte sie und glitt dem erschrocken Aufspringenden in den Arm.

Er führte sie langsam zu ihrem Lehnstuhl, besorgt, über sie gebeugt. Jetzt war er ganz bei ihr.

»Ist dir besser?« fragte er herzlich und zog sich einen der niedrigen Polstersessel vom Kamin heran, »die Selbständigkeit bekommt dir schlecht, meine arme Bel.«

Sie sah den Scherzenden mit einem langen, stillen Blick an.

»Ich muß sie doch lernen, Erik!« entgegnete sie doppelsinnig.

Sie lehnte den Kopf müde zurück und schloß die Augen. Und so, mit geschlossenen Augen, während er ihre Hand festhielt und leise streichelte, sagte sie: »Siehst du, -- ach, Erik, es war ja gewiß recht kindisch. Aber siehst du, -- hierauf hab' ich mich ja schon so lange gefreut. Auf deine Freude, -- wenn ich einmal so zu dir käme, -- ohne Stütze, auf eigenen Füßen. Es war so kindisch. Aber nun ist mir aller Mut abhanden gekommen, dich zu fragen, Erik.«

»Wonach wolltest du mich fragen, Bel?« Er sprach mit gepreßter Stimme, gedämpft, wie immer, wenn er eine Erregung niederhielt.

»Ja, Erik, ich dachte: wenn du dich nun so freutest, und mich in die Arme schlössest, -- nicht wie jetzt, weil ich fiel, sondern weil ich stand, aufrecht neben dir stand, -- dann wollte ich dich fragen, -- ganz leise wollte ich dich fragen, -- ach, Erik! ich kann es nicht mehr.«

Er faßte ihre beiden Hände in die seinen und blickte durchdringend, mit gespanntester Aufmerksamkeit in das erblaßte Gesicht mit den fest geschlossenen Augen. Sein Herz schlug hart gegen die Brust.

»Ich will es dir sagen, Bel!« erwiderte er fest, ohne den Blick von ihr zu lassen, »wenn es dich gequält hat, dann muß es sein. Hast du den Mut, es zu hören? Willst du es?«

Sie schlug ihre Augen auf, -- hilflos, thränengeblendet, -- hilflos wie ein gestelltes Wild vor dem Schuß.

»Erik!« stieß sie flüsternd heraus, und das Entsetzen vor seiner Antwort vergrößerte ihre Augen, »-- Erik, liebst du sie?«

Da beugte er den Kopf tief nieder auf ihre Hände.

»Ja, Bel,« sagte er laut.

In demselben Augenblick durchflutete ein so breiter Sonnenstrom das ganze Zimmer, daß Klare-Bels Lider sich unwillkürlich davor schlossen, in einem abergläubischen Erschrecken, wie wenn der Himmel selbst Zeugnis ablegen wollte für Eriks Liebe. Blau lachte es herab, und wie ein blitzendes Goldnetz von Tauperlen blinkten die rasch zerronnenen Schneefederchen über dem Garten. So warm spielten die hellen Sonnenstrahlen über den Fliederstrauß am Fenster hin, als sei er draußen vom Strauch geschnitten.

»Dunkel,« bat Klare-Bel leise, »-- ich möchte auf mein Bett, -- mach's dunkel.«

Er hob sie aus dem Stuhl und legte sie in ihrem anstoßenden kleinen Gemach auf ihr Bett, hinter welchem er die Fenstervorhänge aus den Klammern löste und zuzog.

Sie suchte nach seiner Hand.

»Die Briefe, Erik, -- wie du ihr geschrieben hast, -- war es lauter Verstellung? Oder hast du ihr -- hast du nicht auch anders geschrieben? Niemals?«

»Ich habe ihr auch anders geschrieben, Bel. Ganz anders. Jedes einzige Mal, daß ein solcher Brief an sie abging. Aber es war nur für mich allein. Sie hat's nie gelesen.«

»Du hast es nicht abgeschickt? -- Hast du diese Briefe noch, Erik?«

»Nein. Ich habe sie jedesmal, sobald sie geschrieben waren, vernichtet.«

»Wozu hast du es dann nur gethan, Erik?«

»Es half mir.«

Fast hätte er hinzugefügt: »Ich liebe sie ja, Bel! Ich liebe sie! Ich mußte zu ihr sprechen.«

Nach einer Weile ließ Klare-Bel seine Hand los und sagte leise: »Und ich hatte keine Ahnung, -- nein, keine Ahnung hatte ich, daß du sie um deswillen von dir gabst. Nun erst weiß ich es.«

Er richtete sich betroffen auf. Mißverstand sie ihn jetzt nicht? Meinte sie nicht, er habe Ruth von sich gegeben um ihretwillen? um Herr zu werden seiner Liebe?

Mußte er ihr die letzte, die tödlichste Kränkung zufügen: »Nicht an dich habe ich dabei gedacht.«

Ja, einmal mußte auch das sein. Aber mußte es heute sein? Alles heute? Litt sie nicht genug, -- maßlos?

Er vermochte es nicht.

Da Klare-Bel nicht mehr zu ihm sprach, trat er von ihrem Bett zurück, an die offene Thür des Wohnzimmers.

Gräßlich war es, einen Wehrlosen niederzuschlagen mit der Faust. Das Mitleid überfiel ihn mit nie gekannter mitleidsloser Macht, -- mit einem nie gekannten wehen, elenden Gefühl umkrallte es ihn.

Das Kaminfeuer knatterte hoch auf unter kurzen Windstößen; der Himmel hatte sich längst wieder verfinstert. Von neuem stäubte ein feiner Schneeschauer um das Fenster, -- dasselbe Aprilspiel wie zuvor.

Erik warf gedankenlos eine Handvoll Tannenzapfen in die rote Glut, und ein schwacher Duft, den er liebte wie keinen andern, -- ein Duft nach Wald und Weihnachten verbreitete sich in der Stube. Unwillkürlich dachte man sich den kahlen, kalten Garten im Winterfrost und einen geputzten Christbaum in der Zimmerecke.

Weihnachten, -- -- -- auch in diesem Winter hatten sie den Baum geschmückt und sich um ihn geschart, aber zum erstenmal hatten sie sich wie drei arme Erwachsene gefühlt, die am Fest der Kinder leer ausgehen. Erik, der zu beschenken wußte, wie nur ein Knecht Ruprecht, und sich zu freuen, wie nur ein Kind, war karg, -- war wortkarg geblieben.

Es kam ihm selbst sonderbar vor, daß sich sein Mitleid an lauter solche kleinen, kleinlichen Rückerinnerungen heftete.

Langsam begann er im Zimmer auf und ab zu gehen.

Nicht daß sie jetzt dalag und litt, -- aber daß sie so lange -- lange umsonst auf seine Freude gewartet hatte, in seinen Zügen nach Freude gespäht, all diese Monate hindurch, -- das erschütterte ihn so tief. Genesen war sie, -- wie ein strahlender Weihnachtsbaum hätte das mitten unter ihnen stehen sollen zu jeglicher Stunde, lichterblitzend, mit tausend neuen kleinen Freuden geschmückt. Und sie hatten sich nicht wie frohe Kinder darum geschart -- --.

Klare-Bel lag noch immer und schwieg. Er mochte nicht zu ihr hineingehen, er mochte nicht fortgehen. Noch immer ging er auf und ab, wie ein Verurteilter.

Endlich kam Jonas. Die Stufen zur Terrasse sprang er herauf und hielt schon am Fenster zwei Briefe in der Hand hoch. Beim Eintreten in das Wohnzimmer warf er sie auf den Eßtisch.

»Wo ist denn Mama? Mehr war nicht in der Stadtwohnung im Briefkasten. Zwei an dich.«

»Mama ist nicht ganz wohl. Sie liegt auf ihrem Bett.«

Während Jonas ans Bett trat, leise, auf den Fußspitzen, griff Erik nach den Briefen. Der eine von Frau Römer, der andre von Warwara. Ohne zu wissen, warum, erbrach er Warwaras kurzes Billet zuerst: die Bitte, morgen bei ihr zu speisen; sie bäte um

Nachrichten über Bels jetziges Befinden und wünsche auch, ihm eine Mitteilung zu machen; in etwa einer Woche verreise sie bereits ins Ausland.

Erik setzte sich an das Fenster und öffnete Frau Römers Brief. Ein längerer als sonst. Acht Seiten.

»Lieber Freund!

Heute schreibe ich in einer besondern Angelegenheit, die unsre Ruth betrifft. Aber erschrecken Sie nicht, denn erstens ist es nichts zum Erschrecken, und dann ist es auch noch keine Wirklichkeit, sondern vorläufig nur eine Möglichkeit.

Sie erraten wohl, daß es sich um Jurii handelt. Ich wußte wohl von seiner jugendlichen Schwärmerei für Ruth, ohne sie besonders zu beachten. Dergleichen ist am Ende kein Unglück für einen jungen Menschen. Jetzt aber glaube ich, daß er Ruth ernsthaft liebt, und daß er im Begriff steht, um sie zu werben. Dies ist nun von geringem Interesse für Sie, es sei denn, daß Ruth ihn wiederliebt. Dafür habe ich keinerlei stichhaltigen Beweise. Aber das Wunderliche ist, daß man nie ganz ergründen kann, was in Ruth vergeht, und wie sie in ihrem innersten Herzen denkt. Nie sah ich einen Menschen, der offener, nie einen, der verborgener gewesen wäre als sie. Offen: bewußt; verschlossen: unbewußt. Es ist, als führe sie, noch hinter allem andern, was sichtbar wird, ein geheimes Eigenleben für sich, von dem sie selbst nicht recht weiß, aus dem aber dennoch alle entscheidenden Gefühle und Gedanken bei ihr kommen. So könnte sie recht gut einmal sich selbst zur Ueberraschung handeln, -- ihrer ganzen klaren, frischen, heitern Unbefangenheit zur Ueberraschung, -- und gerade damit ihr eigentlichstes Selbst erst zum Ausdruck bringen. --

Aber nun zu Jurii. Ich kann über ihn nur Gutes, ja Vortreffliches mitteilen. Ich kann es nur in die Worte fassen: hätt' ich eine Tochter, -- mir sollt's recht sein. Er ist brav, sympathisch, sehr begabt, ernst in der Richtung seines Wesens und seiner Interessen. Gänzlich unverdorben. Dazu kerngesund und ein bildhübscher Junge. Das ist viel auf einmal. Ueber Familie und Verhältnisse wurde Ihnen selbst schon das Beste bekannt. Seine große Jugend ist kein Fehler, da Ruth denselben mit ihm teilt, und da die Zeit ihn so gründlich heilt.

Aber glauben Sie, bitte, trotzdem nicht, daß meine Wünsche Ruth vorauslaufen, -- auf Kupplerfüßen laufen. Ich wünschte nur, Sie rechtzeitig vorzubereiten, damit Sie überlegen, wie Sie sich zur Sache stellen wollen. Denn gegen Ihren Willen, -- nein, auch nur ohne Ihren vollen Willen, -- würde ja wohl Ruth nie etwas thun --«

Erik las nicht weiter.

Er überflog die nächsten Seiten: sie handelten nicht mehr hiervon.

Ruths Schweigsamkeit, -- war sie doch gewollt, bewußt? Abkehr von ihm, eine stille Wandlung?

Er glaubte seinen eigenen erwachenden Zweifeln nicht. Aber sie kamen wieder. Hell und dunkel, Licht und Schatten glitt es über seine Gedanken hin, wie draußen.

»Aprilwetter, -- in mir! um einen Knaben!« murmelte er im Zorn über sich; »in Angst um eine Aprillaune, -- in Angst, in den April geschickt worden zu sein!«

Er war so zornig, so ungerecht als möglich, gegen sie, gegen sich selbst.

Beim Heraustreten aus dem Zimmer der Mutter sah Jonas den Vater über die Terrasse in das Schneegestöber hinausgehen.

Und Klare-Bel wollte ruhen, wollte allein sein.

So schlich er sich in seine Stube.

Als Erik nach ein paar Stunden nach Hause kam, bemerkte Gonne gegen ihn, die Frau habe sich zur Ruhe begeben, sie sei krank.

Erik ging zu ihr.

Sie saß aufrecht im Bett; auf dem Tischchen daneben lagen Bücher. Im Nachtjäckchen, ihre kleine Haube auf dem, wie zur Nacht, glatt zurückgestrichenen blonden Haar, sah sie ihm verwirrt und angstvoll entgegen. Als fürchte sie sich vor ihm. Als schäme sie sich vor ihm.

Er ertrug es nicht. Er beugte sich über sie, das Gesicht auf ihren Händen, und küßte diese.

»Bel, -- Bel, -- verzeihe mir.«

Sie gab sich Mühe zu lächeln; es war ein merkwürdiges, schwaches, kleines Lächeln, das dabei herauskam. Und nun wurde sie dunkelrot.

»Ach, Erik, -- nicht so. Es ist mir zu -- es ist mir so ungewohnt. Schrecklich ist es mir. Sprich nicht so zu mir.«

Er setzte sich neben sie, auf den Stuhl an ihrem Bett.

»Lasest du, Bel?« fragte er zerstreut, gepeinigt.

»Ja, Erik. Du mußt nicht böse darüber sein. Es sind so alte Bücher, -- die alten, weißt du? Aber neulich fand ich einmal etwas, und das machte mich so glücklich. Das suchte ich mir heute auf. Es ist so schön zu lesen, Erik.«

Sie sprach rasch, befangen, wie ein verlegenes Mädchen.

Er blickte nieder auf die Bücher. Ein goldenes Kreuz auf dem einen. Und das andere. P. A. de Génestets »Laiengedichte«, -- diese echt holländischen Lieder, in denen Trotz und Glaube, Trost und Zweifel sich seltsam genug mischen.

»Ich hatte sie so völlig vergessen, alle beide. Weiß selbst nicht, wie nur. -- Wie gut, daß so etwas dableibt, ob man es auch vergißt. Sie waren so verkramt, und ganz staubig, als ich sie neulich fand. -- Willst du mir die ›Laiengedichte‹ herreichen, Erik? Ein Lesezeichen liegt drin.«

Er schlug das Buch auf und reichte es ihr. Das Lesezeichen fiel dabei heraus.

»Höre nur, -- Erik, -- nur einige Verse, magst du? Auch du mußt es schön finden. Es heißt ›+Peinzensmoede+‹. Es sollte wohl heißen: ›Ich glaube, Herr, hilf meinem Unglauben‹.«

Und sie las mit ihrer sanften Stimme:

»Wo -- wo sind die Priester, Die dich erklärten? In Rätseln wandelt Der Mensch auf Erden. Geheimnis -- das Leben, Geheimnis -- der Tod, Die Schöpfung, sie predigt Keinen liebreichen Gott. Natur nur umgibt dich, Die nicht auf dich hört, Gleichviel ob sie wohlthut Oder ob sie zerstört.

Und doch, -- nisten Zweifel Mir auch in der Brust, -- An dich, meinen Vater, Glaub' ich unbewußt. Nicht weil deine Schöpfung Dein Lieben enthüllt, -- Nein! nein! nur trotz allem, Dem Zweifel entquillt! Trotz jeglichem Rätsel, Trotz jeglicher Not, Trotz Angst und Verderben, Trotz Schmerzen und Tod!

Ich schmachte, vom Schicksal Zu Tode getroffen, Meine Hoffnung ist Wehmut, Meine Wehmut ist Hoffen. Ich ~will's~ -- ~will~ es glauben, Daß ich deine Hand Im Leben wohl spürte, Nur sie nicht erkannt; -- ~Will's~ glauben, was Kirche und Priester mich lehrten: Daß niemand umsonst dich Gesucht hat auf Erden.«[1]

[1] Frei nach dem Holländischen.

Sie saß da und las, den Kopf mit dem weißen Nachthäubchen andächtig gesenkt, die Hände auf der Bettdecke gefaltet. Die Röte der Befangenheit, der verlegene Ausdruck wichen langsam von ihrem Gesicht; rührend und vertrauensvoll sah sie aus, wie ein Kind, das seiner Mutter ein Gebet nachspricht.

Und so nackt legte sie auch jetzt noch ihre Seele -- in all ihrer Hilflosigkeit und zagenden Hoffnung, vor ihn hin, -- ohne jeden falschen Stolz. Sie kannte es nicht anders.

Erik hielt noch immer das Lesezeichen in der Hand und betrachtete es geistesabwesend. Ein recht unpassendes hatte sich da ins Buch hinein verirrt: ein nackter Amor mit einem großen Rosenbouquet.

Während er aber stumm darauf hinschaute, sprach er in Gedanken zu Klare-Bel, unterbrach sie im Lesen, nahm ihr das Buch aus der Hand. Er war ganz eingenommen von diesem wortlosen Zwiegespräch: »Dieser Titel gehört sicher nicht über deinen Glauben und deine Zweifel, Bel; ›+Peinzensmoede+‹ bedeutet ja: des Sinnens, des Grübelns müde. Wann hättest du das gekannt? Ein vom Zufall der Erziehung lässig dir übergeworfenes Kleid, -- ein durch einen Zufall deiner Ehe lässig von dir abgeglittenes Kleid: das war in deinem Leben der Glaube.«

Und in Gedanken hörte er Klare-Bel: »Woran soll ich denn aber noch glauben, Erik? An dich? Doch nicht an dich? Von wo einen Halt nehmen? Du warst mein Halt. Ach, der hält nicht! Er biegt sich unter meiner Hand hinweg, und läßt mich stürzen. Soll ich mir selbst ein Leid anthun? Dich ermorden? ~Sie~ vergiften? Ich bin keiner von den Menschen, über denen die Leidenschaften vernichtend zusammenschlagen. Bin ich dadurch nicht nur hilfloser? Meine tiefste Verzweiflung heißt Hilflosigkeit; -- das Tasten nach einer Stütze: mein letzter klarer Gedanke. Warum verwehrst du es mir?«

»Weil ich diese Stütze hasse, -- diesen Halt, der mich ersetzen soll. Nein, weil ich mich dessen schäme, -- daß er mich ersetzen muß. Weil ich kein Mitleid mehr mit dir habe, -- nur noch Zorn und Haß und Scham vor mir selbst.« -- -- -- -- -- -- -- -- -- -- -- --

Klare-Bel schaute von ihrem Buch auf, unsicher gemacht durch sein Schweigen.

»Ist es nun nicht schön, Erik?« fragte sie leise, beinahe bittend, »-- mich macht es glücklich.«

»Dann ist es schön, Bel!« sagte er sanft. --

Aber seine Stimmung war nicht sanft. Den ganzen Abend schlug er sich mit einer ihm fremden Pein herum. Schon am Vormittag, -- als er seine Frau nicht sofort über ihr Mißverständnis aufklärte, sondern sich edler nehmen ließ, als er war, -- und jetzt wieder, wo seine Lippen anders redeten, als seine beschämten, zornigen Gedanken, -- hatte er gegen seine innerste Natur gehandelt, sich passiv verhalten, die Dinge gehen lassen. Nicht aus einer Weichlichkeit des Mitleids, -- aus gerechter Ueberzeugung: ob es ihm sympathisch oder widerwärtig war, durfte nicht in Betracht kommen gegenüber dem, was Klare-Bel durch ihn erleiden mußte.

Er hatte sich unausweichlich in die Lage gebracht, gegen seine eigenste Natur handeln zu müssen.

Den nächsten Tag bedurfte Erik einer gewaltsamen Willensanstrengung, um seine Gedanken von allem loszureißen, was ihn quälte, und auf seine Arbeit zu richten. Bald sah er Bel als Betschwester vor sich, bald Ruth als Braut; Hohn und Erbitterung erfüllten ihn. In beiden Fällen war er der entthronte König.

»Einen neuen Gott die eine, -- einen neuen Mann die andre, -- es ist fast dasselbe!« dachte er und erschrak selbst vor der Häßlichkeit seiner Gedanken.

In einer Pause zwischen seinen Schulstunden, während welcher er in der Stadtwohnung vorsprach, zog er Frau Römers Brief aus seinem Taschenbuch. Er hatte ihn nicht einmal ganz gelesen, -- nur durchflogen, -- und jetzt kam ihm das Gefühl: es müsse wohl thun, diese Frau reden zu hören, bei ihr Ruhe zu finden vor all dem Häßlichen, was in einem Menschen aufgewühlt werden kann.

Und er las weiter.

»Es ist ja nicht notwendig, daß Ruth sich schon so jung bindet. Vielleicht wird sie sich erst viel später verheiraten, -- vielleicht nie. Nun sehen Sie, dies wäre nicht wünschenswert. Ich weiß nicht, wie Sie darüber denken. Ich spreche als glückliche Frau naturgemäß für die Ehe. Aber ich habe gut reden: ohne meinen Mann wäre ich wohl ein nichtsnutziges Ding geblieben, -- mit etwas Interesse für Tand und einer großen Leere im Herzen. Ich glaube, Sie legen einen Hauptwert auf Ruths geistige Entwickelung. Ich auch. Aber dazu verhält sich ein frühes gleiches Liebesleben nicht als Gegensatz, sondern als die einzige gesunde, natürliche Grundlage auch des Geistesstrebens im Weibe. Nicht nur damit Sie Gehilfin des Mannes sei. Häufig langt es ja gar nicht zu mehr. Wo es aber langt, -- desto besser. Von meinem Mann glaube ich bestimmt, daß er mich im Ergreifen eines jeden Berufes unterstützt hätte, zu dem eine entsprechend große Befähigung vorhanden war. Nicht aus reiner Selbstlosigkeit natürlich. Liebe ist nicht selbstlos. Wohl aber, um den ganzen frischen Duft, die ganze Fülle und Freude um sich zu haben, die nur derjenige Mensch auf seine Umgebung ausstrahlt, der voll erblüht. Und daß zwei Blüten bei einander stehen wollen: das bedeutet ja wohl ›Ehe ‹ --.«

Erik sprang auf und warf den Brief auf den Tisch. Etwas ganz andres, als er gesucht, hatte er darin gefunden, -- etwas ganz Unerwartetes: einen unbewußten Vorwurf.

Seine Ehe mit Bel, das waren keine zwei selbständigen Blüten, die zusammenstanden: das war eine Blüte, die einen Tautropfen aufgesogen, der unvorsichtig in ihren Kelch gefallen war.

So würde es wohl Frau Römer ausdrücken.

Römers standen eben von vornherein anders zu einander. Sie bewunderten sich gegenseitig, -- eigentlich war es rührend. Man konnte nicht recht darüber lächeln: man mußte diese beiden Menschen achten.

Bel konnte aber nicht mit Frau Römer verglichen werden. Als er sie fand, ein Jahr älter als er selbst, sinnbethörend schön, bereits fertig mit ihrer kurzen Entwickelung, -- ein in gewisser Weise viel fertigerer Mensch als er, -- was hätte er da wohl andres thun können, als dürstend in sich aufzusaugen, was, nach Selbstuntergang sehnsüchtig, sich ihm darbot?

Aber wenn man einen schwächern Menschen so absolut in seinen Besitz nimmt, so fühlt man die furchtbare Verpflichtung: ihn nicht wieder von sich zu lösen. Man stellt sich für das ganze Leben in einen Kampf hinein zwischen Scham und Mitleid, bei jedem leisesten Versuch, sich dieser Verpflichtung zu entziehen.

Wahrscheinlich würde das Frau Römers Meinung sein. -- Auch -- Ruths Meinung? Ruth grübelte nicht über solche Fragen. Aber was täglich, stündlich auf sie wirkte, sie beeinflussen mußte, mächtiger als alle Worte, alle Grübeleien, -- das war Frau Römers Ehe. Eine heilig gehaltene, glückliche Ehe.

Sobald sein Unterricht ihn freiließ, ging Erik zu Warwara. Mehr, als er es sich selbst gestehen wollte, war es ihm recht, jetzt noch nicht nach Hause zu fahren.

Als Erik gemeldet wurde, entfernte sich eine lange, hagere Engländerin, Warwaras Gesellschafterin, aus dem Zimmer.

»Sie sehen ganz besonders ernst aus,« bemerkte er bei der Begrüßung zu Warwara, »es ist Ihnen inzwischen doch nichts Unangenehmes passiert?«

Sie mußte hell auflachen.

»Etwas passiert, -- ja. Aber man zählt es nicht zum Unangenehmen.«

»-- Verlobt?! -- war das die Mitteilung?! -- Mit wem?«

Sie setzte sich in ihre Plauderecke. »Gleichviel, mit wem. Ein Ihnen ganz Fremder. Im Auslande. Sie werden es auf einer schön gestochenen Verlobungskarte lesen.«

»Und darf ich Ihnen Glück dazu wünschen, Warwara?«

»Wie meinen Sie das?«

»Ich meine natürlich, ob Sie das Geringste für den Mann fühlen, den Sie heiraten wollen.«

»Daran zweifeln Sie?«

Er schwieg.

»Ich will es Ihnen sagen. Dazu rief ich Sie ja her. Ich hab' ihn gern. Sehr gern. Aber mir wird nicht heiß und kalt, wenn ich an ihn denke.«

»Und das scheint Ihnen zu genügen. Es genügt nicht, Warwara.«

»So will ich Ihnen noch mehr eingestehen. Was ich in der Ehe suche, -- das Glück, das ich suche, -- ist nicht der Mann.«

»Sondern?«

Sie stand auf und trat an ihren Blumentisch, mit dessen Pflanzen sie sich zu schaffen machte.

»Das Kind.«

Erik schwieg überrascht.

Nach einer kurzen Pause sagte sie: »Es ist ein sehr vertrautes Geständnis. Aber ich bin mit Ihnen sehr vertraut, -- mehr, als Sie wissen. Hab' Sie oft so im stillen bei mir selbst um allerlei Rat gefragt. Sie zum Beichtvater und Seelsorger gehabt. Wir hätten öfter, als wir gethan, ernste Dinge miteinander teilen sollen.«

»Das hätte mich sehr froh gemacht, Warwara. Schon das, was Sie da sagen, macht mich froh. Ich bedurfte gerade dessen.«

»Nun, sehen Sie, das ist gut. So will ich's auch ruhig bekennen. Daß ich wirklich nur ein ganz armes Weltkind bin, voll von allerlei Tand und Plunder. Und daß ich gern mehr sein möchte. Vielleicht dank Ihnen, -- dank den stillen Unterhaltungen, die ich da

mitunter mit Ihnen geführt habe. Und so will ich mir denn nun den einzigen Erzieher und Meister ersehnen und erwünschen, der aus mir noch das Beste machen kann, -- das Beste, was in mir ist.«

»Das alles erwarten Sie von einem Kinde?«

»Von der Mutterschaft -- ja. Von der Mutterliebe. Dem Mutterglück. Der Mutterpflicht. -- Und dann,« sie wandte sich lebhaft zu ihm, »irgend wann einmal, wenn ich wirklich so glücklich sein soll, dann gebe ich mein Kind in Ihre Hand, damit Sie es zu einem tüchtigen Menschen heranziehen helfen, Sie Menschenlehrer.«

»Hätten Sie ~das~ Vertrauen zu mir? Ein so festes? Einen ganz festen Glauben an mich? Ich danke Ihnen, Warwara.«

»Ja. Ich traue Ihnen und Ihrer Kraft unendlich viel zu. Unter der einen Bedingung: daß Sie Ihre Aufgabe sehr lieben.«

»Mit andern Worten, keine Kraft zur Pflichttreue.«

»Das weiß ich nicht. Ich glaube nur, trotz allem, daß Sie im Grunde Gemütsmensch sind. Und das heißt doch nur: sehr lieben können, -- Menschen oder Ideen, -- und da, wo man sehr liebt, sich rückhaltlos verschenken können. Hingegen all das andre, was Sie bisweilen mit solchem Selbstvertrauen zu behaupten pflegen, -- all die Sicherheit und Unfehlbarkeit außerhalb dieser leitenden und entscheidenden Gefühle, -- nein, -- daran glaub' ich auch für Sie nicht.«

»Sie sind eine große Philosophin geworden,« bemerkte er halblaut.

»Wie? Sie geben's mir zu?« fragte sie überrascht, »welch ein fremder, guter Geist der Nachgiebigkeit ist denn nur über Sie gekommen? Aber es ist wahr, warum sollten auch Sie es nicht einmal fühlen, wie abhängig wir alle vom Glück sind, -- wir armen Weltkinder alle? Vom fruchtbaren Erdfleckchen, auf dem auch für uns noch ein ganzes Glück, eine ganze Liebe, -- und dadurch allein! -- auch eine ganze Pflicht und Heiligkeit wachsen kann.«

»Und wenn wir dies Erdfleckchen, gerade dies, nicht bebauen dürfen?«

»Dann verdorren wir, -- oder verschleudern uns. Wenigstens ich. Und Sie auch.«

Ein Diener erschien in der Portierenthür und bat zur Tafel.

Warwara stand auf.

»Geben Sie mir den Arm. So ernst? Ich habe Sie doch nicht verletzt?«

»Nein. Sie haben ganz recht. Hatten recht, als Sie einmal vor langer -- sehr langer Zeit zu mir sagten: ›Wir haben eine gemeinsame Versuchung.‹ Es erkennen, heißt hart werden, -- gegen alles, was uns hindert, uns fruchtbar auszuleben.« --

Auf dem Lande saßen Klare-Bel und Jonas nebeneinander bei Tisch. Jonas fand: einander gegenüber, das sei zu feierlich. Es machte ihm Spaß, dabei die Mutter zu bedienen und ihr vorzulegen, von allem das Beste. Er war bemüht, sie zu unterhalten.

Klare-Bel hörte nicht recht hin; ihre Blicke hingen an einem Brief, den Jonas mitgebracht hatte. Er war erst nach Eriks Anwesenheit in der Stadtwohnung dort eingelaufen.

Von Ruth. Ganz außer der Zeit. Klare-Bel konnte eine schwache, thörichte Hoffnung nicht unterdrücken, die mitten in Jonas' harmloses Geplauder hineinredete.

Als Erik, bald nach dem Abendthee, zu Hause eintraf, bemerkte er sofort den Brief, der für ihn bereit lag. Sein Blick streifte Jonas, -- flüchtig nur, -- aber Jonas stand sofort auf, um hinauszugehen. Der Vater wußte doch ganz gut, wie schwer ihm das fiel, -- aber er sollte ihm nicht noch einmal, wie in jener Nacht vor Ruths Abreise, Mangel an Selbstbeherrschung vorwerfen. Jonas gehorchte ihm jetzt immer blind, -- auf den Wink; denn schickte er ihn auch aus dem Zimmer: er führte ihn ja doch den Weg zu Ruth.

Klare-Bels Augen hingen mit unaussprechlicher Spannung an Erik, während er den Brief erbrach. Eine einzige Sekunde, -- die Seite umgerissen, -- eine zweite, blitzschnell, -- und er ballte das Papier in der Hand.

Er war grau im Gesicht.

»Erik! was ist es? -- etwas Schlimmes, -- für dich Schlimmes, -- Erik!«

Sie entsetzte sich vor dem veränderten Ausdruck in seinen Zügen.

Er entfaltete das Papier wieder, nur die Hand ballte er. Vor seinen Gedanken schwirrten vier Worte: »Ich habe ihn lieb«, und, am Schluß, etwas wie »den Kuß gab ich ihm«, -- mehr hatte er nicht gelesen. Er biß die Zähne aufeinander.

Das zu lesen, jetzt, vor den Augen seiner Frau.

Er las es, aufrecht stehend, hell beleuchtet, vor der Lampe.

»Am Schloßberg. Dienstag.

Ich soll Ihnen von Jurii schreiben, sagt Frau Römer. Ob ich ihn lieb habe. Ich habe ihn lieb. Und ich soll alles so erzählen, wie es gewesen ist. Es ist so gewesen: Um den Schloßberg stürmte und regnete es. Ich durfte nicht in die Stadt hinuntergehen, weil ich mit Husten zu Bett gelegen hatte. Ich ging aber doch hin, um mir ein Buch für meine Arbeit zu holen. Unten fand ich Jurii, und er brachte mich nach Hause. Wir gingen unter einem Schirm und mußten uns gut zusammendrücken. Es war aber sehr glatt, und Jurii mußte immer nur achtgeben, daß ich mit den Galoschen nicht ins Rutschen kam. Da sagte Jurii zu mir: ›Ich liebe Sie. Ich liebe Sie so sehr. Werden Sie, bitte, meine Frau.‹ Das sagte er aber russisch, und darüber fing ich an zu lachen, denn wir sprechen ja immer deutsch. Da sagte er noch: ›Ich weiß jetzt, daß Sie mich nicht wiederlieben. Dann gibt es kein Glück mehr auf der Welt. Sterben möcht' ich.‹ Darüber, daß er sterben wollte, wurde ich ganz traurig, und er wurde es auch. Wir achteten nicht mehr auf den Schirm und auf die Galoschen, ich verlor einen, und der Regen lief uns in den Rücken. Frau Römer schalt sehr, als wir pudelnaß ankamen, steckte mich ins Bett und kochte heißen Thee auf. Ich lag und weinte, denn ich wußte nicht, wie ich es anfangen sollte, damit wir wieder vergnügt sein könnten. An derselben Wand stand aber im Nebenzimmer ein Diwan, und da lag jemand und that dasselbe. Frau Römer kam herein, und horchte, ob nebenan auch jemand weinte und lächelte etwas und sagte, wir wären rechte Kinder. Darauf setzte sie sich an mein Bett und streichelte mein Haar zurück (das thut sie gerade so wie Sie) und fragte: ob ich Jurii denn nicht ein wenig lieb hätte. Ich sagte: ›Ja.‹ Da sagte sie: ›Ich meine es anders. Denke einmal nach, was dir das Schönste auf der ganzen Welt ist? gehört Jurii dazu?‹ Ich dachte nach und sagte, das Schönste auf der ganzen Welt sei ja, daß ich Ihr Kind sei. Darauf sagte sie: ›Vielleicht jetzt noch. Aber kannst du dir denn nicht denken, daß es später noch viel, viel schöner wäre, einem andern zuliebe Braut zu sein?‹ Das konnte ich mir nicht denken. Da fragte sie nichts mehr. Sie küßte mich und ging fort.

Heute ist Jurii fortgereist. Er will nicht mehr hier studieren. Ich stand gerade bei meinen vielen Schneeglöckchentöpfchen, die ich im Februar unten in der Gärtnerei gepflanzt habe. Ich schnitt die aufgeblühten ab für Frau Römers Glas, damit sie wieder gut sein sollte. Da kam Jurii in mein Zimmer. Er wollte die Blumen haben und einen Kuß. Er sah so blaß und verweint aus. Ich gab ihm die Blumen. Und den Kuß gab ich ihm auch.

So ist es gewesen.

Ruth.«

Klare-Bel hatte ihre Augen vom Lesenden abgewendet. Sein Gesicht verriet alles, was im Brief stand. Allzu deutlich verriet es, daß sein Schreck umsonst gewesen war.

Erik in dieser Abhängigkeit zu sehen von dem, was Ruth that oder unterließ, -- das war gräßlich. Das wollte sie nicht sehen.

Sie hatte gemeint, das Schwerste sei über sie gekommen: gestern. Aber nicht, es zu wissen, war das Schwerste, -- nein, es mit wissenden Augen zu beobachten, täglich, stündlich, es bestätigt zu finden in solchen kleinen Vorgängen. Dieses Lieben und Schwanken mit anzusehen, -- das war schwerer. Nicht nur schwerer, -- unmöglich war es.

Und dann, -- wenn Ruth einen andern abwies, -- dann liebte wohl auch sie Erik. Und wenn sie ihn liebte -- dann erst war er für Bel verloren. Auf sein Glück konnte er vielleicht verzichten -- für Bel; auf Ruths Glück nie. Nicht, wenn er sie wirklich liebte. Wo die stärkere Liebe blüht, da wächst auch das stärkere Pflichtgefühl: da sorgt man nur noch um das Glück des andern.

So empfand Klare-Bel.

Am nächsten Tage fehlte sie beim Morgenfrühstück. Gonne hatte es ihr auf ihr Zimmer bringen müssen.

Erik suchte sie sofort auf. Er war schon in aller Frühe aufgestanden und hatte, nach mehreren vergeblichen Versuchen, Ruth geschrieben. Aber diesmal gelang es ihm schlecht, -- ein gequälter Ton klang durch.

Klare-Bel lag im Morgenrock auf ihrem früheren Ruhestuhl, eine Felldecke über den Knieen. Sie sah nicht krank aus. Vielmehr klar und gesammelt.

»Du bist doch nicht leidend?« fragte er dennoch, mit ehrlicher Sorge.

»Ich bin nicht leidend, Erik. Aber ich mußte dich bei mir haben. Allein -- ganz allein, -- ohne Jonas.«

Und sie umfaßte seine Hand mit ihren beiden Händen.

»Um dich zu bitten: laß mich jetzt abreisen! Jetzt schon. Es sollte ja doch bald sein. Laß es jetzt sein!«

Er schwieg einen Augenblick. Diese Bitte war beredt.

»Wenn du es durchaus willst, Bel. Dann soll es beeilt werden. Ich will alle Sorge dafür tragen. Ich bin jetzt gebunden. Aber Jonas soll dich hinbringen.«

»Ach nein, Erik! Laß mich allein hin. Nicht mit Jonas. Gonne genügt. Ich bitte dich so sehr darum. Mit Jonas bin ich nicht allein. Er hat so feine Augen. Vor ihm will ich nicht --«

Sie brach ab; aber der einzige Stolz, den sie besaß, ihr Mutterstolz, schrie in ihr: »Vor ihm will ich mich nicht in meiner Schwäche zeigen, in meinem Elend!«

»Nun gut. Auch das. Dann soll er dich nur bis über die Grenze bringen. Darauf bestehe ich, Bel.«

»Ich danke dir. Und nun muß ich dir noch das andre sagen, Erik.«

»Was denn?«

Er schritt unruhig ein paarmal durchs Zimmer und lehnte sich ans Fenster. Sie sprach so klar und so ruhig bewußt. Er kannte seine Bel vollkommen, -- jede leiseste Regung in ihr kannte er, -- und beeinflußte er. Und nun ging von ihrem Wesen ein ihm Unbekanntes, ihm Entrücktes aus, -- etwas Fremdes. Er fühlte es, ohne es sich noch erklären zu können, wie einen Druck auf die Nerven. Ein ganz seltsames Gefühl: als sei noch ein Dritter im Zimmer.

»Ich will es nur lieber schnell heraussagen, Erik. Das andre ist, daß auch du verreisen sollst, -- so bald als möglich. Nicht erst zum Sommer, um mich abzuholen. Bald, -- eher, -- in den Ostertagen. Wo du zwei Wochen Zeit hast. Um sie wiederzusehen. Um dich zu überzeugen, ob wohl auch sie -- --. Ganz gewiß, das mußt du thun. Denn sonst bist du zeitlebens unglücklich, Erik. Und das -- siehst du -- das könnt' ich ja nicht aushalten.«

Die Röte war ihm übers Gesicht geschossen. Dunkelrot bis über die Stirn. Er warf den Kopf zurück gegen das Fensterglas.

Das war es: eine neue Stütze besaß sie, die sie selbständig gehen und handeln lehrte! Einen neuen Herrn: schon handelte sie auf sein Geheiß!

Wie hatte er nur an Kampf denken können -- mit Bel! Kampf? Nein, ausrauben, ausplündern wollte er sie! Aber sie ließ es nicht zu: sie beschenkte ihren Räuber, -- freiwillig, überreich beschenkte sie ihn: »Nimm, du Armer, vom Glück Abhängiger, -- ich kann's entbehren, bin die Stärkere, -- ich kann entsagen, -- du -- nicht.«

Und glühend brannte in ihm die Scham empor, -- glühende Scham, -- und Auflehnung als einzige Antwort: »Tausendmal lieber ein Räuber als ein Beschenkter!«

Klare-Bel sah den Schweigenden, Wortlosen nicht an. So ganz ergriffen und benommen war sie von dem Schweren, das sie vorhatte, daß ihre Blicke ihn nicht suchten, nicht befragten, wie sonst wohl.

»Heut nacht lag ich immer und dachte: wenn es anders möglich wäre! Aber das ist es ja: es ist nicht möglich. Du kannst nicht aufhören, an sie zu denken, und ich, -- wie sollte ich, -- wie sollte ich nicht anfangen, sie zu hassen? Und so versündigen wir uns aneinander, Erik. Das soll nicht sein. Es ist immer alles schön gewesen zwischen uns. Es kann traurig werden, -- sterbenstraurig. Aber nicht häßlich. Das soll es nicht. Ich ertrüg's nicht.«

Ein halber Laut entfuhr ihm. Sie, -- was wußte sie wohl von »Haß«. Von Häßlichem. Nein, nichts! Es erfüllte ihn mit einem fast andächtigen Staunen: in ihr wurden die Gedanken nicht häßlich, nicht bitter und ungerecht, im Kampf und Zweifel, im Aufruhr und

Schwanken der Seele. Sie dachte nichts Häßliches.

»Und nun hab' ich auch verstanden, -- heut nacht, -- warum ich gesund geworden bin,« sagte Bel leiser, als er noch immer schwieg, »und warum wir doch dessen nicht froh werden konnten. Nicht froh, obgleich ich auf meinen Füßen stehen und gehen konnte. Gott sprach darin zu mir: ›Geh!‹«

»Bel!« stieß er gequält heraus. Diese religiöse Exaltation war ihm entsetzlich. Aber Klare-Bel sagte ruhig, beinahe freundlich: »Ja, Erik. Und ich gehe. Gott selbst wollte es so. Er wollte es. Aber Jonas mußt du mir später lassen. Bei mir lassen. Jonas gehört mir mehr als dir.«

Höchstes und Alltägliches ging durcheinander. Erik fand: nun redete sie von der Trennung und Scheidung wie von einem Hausumzug; »dies ist mehr mein, -- dies mehr dein.«

Er trat an ihr Bett.

»Höre mich jetzt an, Bel. Du fassest keinen Entschluß -- über nichts, -- ehe ich jetzt zu dir gesprochen habe. Offen. Offener als bisher. Denn du weißt nicht alles.«

»Ach, Erik, -- sage nichts! Es ist schrecklich, es zu hören! -- Nichts, -- nein! Nur eines -- hätt' ich von dir erbeten!«

Er ergriff die Hände, die sie gegen ihn vorstreckte, und hielt sie sanft fest.

»Es ~muß~ sein, Bel. Du mußt mich hören.«

»Warte noch. Bitte, nicht! Erik, -- sage mir nur erst: -- hast du -- ihr schon geschrieben?«

»Ja,« versetzte er erstaunt.

»Ich meine -- den ~andern~ Brief?«

»Ja, -- auch den andern.«

»Und du hast ihn vernichtet. Nicht wahr, -- das hast du doch?«

In diesem Augenblick wußte er es selbst nicht. Unwillkürlich griff er an die Tasche seiner Joppe. Es knisterte leise unter seinen Fingern.

»Erik! -- das ist das Einzige, -- was ich von dir erbitten wollte.«

Seine Hand krampfte sich zusammen um das dünne, zerknitterte Papier, -- wieder stieg eine Blutwelle ihm ins Gesicht, -- wieder die Röte der Scham, einer feinen, empfindlichen Scham. Nein, -- nur das nicht! Das konnte er nicht! Vor Bels Augen das Innerste, Geheimste bloßlegen, -- sein Heiligstes und sein Unheiligstes, -- den Aufruhr der wildesten Stunde, -- die Andacht der stillsten --.

Aber nur einen Augenblick lang zauderte er so. Sie hatte recht, -- tausendmal hatte sie ein Recht darauf! Und was sie daraus erfuhr, war, was sie erfahren mußte, -- sich zu erfahren scheute. Und wenn es mehr war, als sein Bekenntnis hätte aussprechen können, -- wenn er selbst es war, mit allem, was in ihm tobte, gärte, schluchzte, kämpfte, mit allem Häßlichen auch, und dem Aufschrei nach Glück, -- dann war es gut so.

Vor seinen Worten scheute sie sich, -- vor der endgültigen Klarheit: und in dieses Dunkel griff sie verlangend, -- vermessen. Wer ergründet wohl einer Frauenseele Furcht und Neugier!

Er reichte ihr das zerdrückte Blatt, -- zusammengeballt war es zu einer Kugel.

»Du hast es gewollt.«

Dann verließ er sie.

Nebenan im Wohnzimmer stand der Frühstückstisch noch unabgeräumt. Jonas hatte vergeblich auf den Vater gewartet und zur Schule gehen müssen.

Erik blieb in der Mitte der Stube stehen und starrte ins Leere.

»Nicht entsagen!« war sein einziger deutlicher Gedanke. »Nicht entsagen! nicht in der Versuchung des Mitleids, -- nicht in der schlimmern: der Versuchung der Scham.«

Ihm war, als handle es sich gar nicht um einen einzelnen Menschen, noch weniger um ein Weib, -- nein, um alles, was Mensch hieß, was ihm Mensch sein konnte, -- um alles, was er überhaupt berühren konnte, schaffend, wirkend, liebend, -- um sein eigenes Menschsein.

Es konzentrierte sich alles in diesen zwei kindlichen, gläubigen Augen, die auf ihn warteten und zu ihm emporschauten.

Entsagen hieß: in die Wüste gehen, -- nicht nur mit seiner Liebe, -- auch mit seiner Thatkraft, -- mit seiner Kraft überhaupt, -- ins Unfruchtbare, in die tote Einsamkeit.

Gab es eine Kraft auch für die Wüste? Die in solcher Einsamkeit standhielt? Ja, in ihr vielleicht erst erstand? Die nicht mehr eines andern bedurfte, um stark und schön zu bleiben, -- keiner Augen, die da glaubten, und warteten, und an sie appellierten?

Ja vielleicht! für Reflexionsmenschen, die sich selber über die Schulter gucken, sich in sich selbst bespiegeln, -- spottend oder genießend! Oder für Gefühlsmenschen, die in ihren eigenen Erregungen sentimental zu schwelgen und zu schwimmen wissen, -- auch sie ihr eigenes Publikum!

Aber nicht für solche, die in sich selber unteilbar eins sind und daher auch hilflos in sich selber, -- wenn sie sich nicht dadurch helfen können, daß sie handeln, aus sich heraus wirken, -- und sich selbst erkennen, wiedergespiegelt im Auge eines andern.

Aber Bel? Warum konnte sie entsagen? sie, die weder in Reflexionen noch in Gefühlen schwelgte, sie, die vielmehr naiv und schüchtern war und keineswegs ihr eigenes Publikum? Aber so ging es auch: mit dem großen suggerierten Zuschauer, -- mit dem da oben, der alles sah. Auch sie hatte ihren Spiegel, für den sie sich schön erhalten mußte, -- das Gottesauge, den blauen Himmelsspiegel!

Ein schwacher Laut, wie ein Stammeln oder Stöhnen, drang aus Klare-Bels kleinem Nebengemach. Es war, als wolle sie Erik in seinen bittern Gedanken unterbrechen, -- widerlegen.

Er trat zur offenen Thür.

Bel hatte den Brief von sich geworfen, weit fort, auf den unteren Rand der Felldecke. Sie lag da, das Antlitz glutrot, in den Händen vergraben.

»Lieber Gott!« betete sie, »großer, barmherziger Gott, der du im Himmel bist, und in die Herzen der Menschen hineinsiehst, nimm mir meine Liebe aus meinem Herzen!« --

* * * * *

Warwara war sehr überrascht, als sie am nächsten Tage Erik auf der Straße traf und von der bereits jetzt bevorstehenden Abreise seiner Frau hörte. Sie redete auf das lebhafteste zu, noch eine einzige Woche zu warten und Klare-Bel dann mit ihr zusammen hinausreisen zu lassen. Aber es fruchtete nichts. Schon den folgenden Morgen konnte sie der Fortfahrenden, der sie baldigen Besuch im Bade versprach, einen mächtigen Rosenstrauß in das Waggonfenster stecken. Warwara war außer Erik die einzige, die Mutter und Sohn das Geleit gab, und sie fand, daß die Gatten sich nicht ganz unbefangen gegeneinander verhielten.

Nach Abfahrt des Zuges verabschiedete Erik sich nur kurz und hastig von ihr. Sehr nachdenklich fuhr sie nach Hause.

Ihre klugen Gedanken mißverstanden ihn vollkommen. Sie glaubte ihn eigentlich als Mann in seinem eigenen Heim befriedigt, aber als Mensch in seinem Wirkungskreise unbefriedigt. Und wenn sie, scherzend oder ernst, von »Versuchungen« für ihn sprach, so meinte sie damit gelegentliche Versuche, die hungernde Thatkraft durch Näschereien und Tändeleien zu betäuben. War jetzt so etwas im Spiel? Jetzt, wo Erik so völlig zurückgezogen lebte, -- schon seit einem Jahr? Wo er ganz aus der glänzenden, leichtlebigen Welt der Gesellschaft verschwunden war, die ihn einst fesselte, und die er gefesselt hatte? War eine Frau im Spiel? --

Wenige Tage später, an einem Sonntag vormittag, wollte Warwara eine notwendige Besichtigung ihres Landhauses zum Anlaß nehmen, um bei Erik vorzusprechen und zu erfahren, ob Jonas mit guten Nachrichten von der Grenze heimgekommen sei.

Beim Einsteigen in die erste Klasse des finnländischen Zuges erstaunte sie darüber, sich nicht allein zu finden. In der Ecke ihr gegenüber saß eine ganz junge Dame und blickte mit großen, erwartungsvollen Augen zum Fenster hinaus.

Warwara betrachtete sie mit flüchtigem Interesse. Wie immer, fielen ihr zuerst und hauptsächlich lauter einzelne Aeußerlichkeiten auf.

Ein zarter, geschmeidiger Wuchs; das eng anliegende dunkelblaue Tuchkleid mit offenem Jackenteil, auf tiefrotem englischen Flanell abgefüttert, zeigte nur hoch am Halse einen kleinen weißen Linnenstreifen. Ein schmaler Fuß guckte, in ungeduldiger Bewegung, unter dem Rock hervor. Aschblondes Haar, von einer starken Schildpattnadel im Knoten zusammengehalten, drängte sich um Stirn und Schläfen in seinem Gelock aus einem weichen Barett von dunkelblauem Sammet hervor.

In Warwara stieg eine unbestimmte Erinnerung auf, sie wußte nicht, an wen. Eine junge Engländerin? So eindringlich blickte sie auf ihr Gegenüber, daß dasselbe sich ein wenig befremdet nach ihr umwandte.

Ein paar Sekunden lang erwiderte das junge Mädchen fest und forschend ihren Blick. Dann grüßte sie mit einem schwachen Lächeln.

Das Lächeln half Warwara plötzlich auf die Spur.

»Ruth!« entfuhr es ihr. Sie verbesserte sich sofort, lachend: »Verzeihen Sie nur. Die Zudringlichkeit erst und jetzt. Aber ich suchte und suchte, und was ich fand, war, was mir im Gedächtnis geblieben: Ihr Vorname.«

»Es genügt ja vollkommen,« sagte Ruth. »Ich nehme an, wir haben Einen Weg?«

»Nein!« versetzte Warwara mit raschem Takt, denn sie wollte nicht stören, »ich fahre nur zu einer Besichtigung meines reparaturbedürftigen Landhauses hinaus. Aber unsre Freunde erwarten Sie?«

Ruth errötete und schüttelte den Kopf.

»Nein; ich bin sehr -- ganz unerwartet von Heidelberg abgereist,« entgegnete sie mit auffallender Befangenheit.

Warwara durchzuckte blitzähnlich ein Verdacht. »Das ist sie, -- die ›Versuchung‹,« dachte sie, »sehr jung, aber ich argwöhnte schon damals hinter ihren geübten Formen: sehr durchtrieben.«

»Da wird es Ihnen leid thun, eine Lücke zu finden,« bemerkte sie laut, »denn Sie wissen wohl noch gar nicht, daß Sie Klare-Bel nicht treffen? Sie ist schon abgereist.«

»Nein!« rief Ruth betroffen, »das konnte ich ja noch nicht wissen! Es hat doch keinen schlimmen Grund? Ja, das thut mir leid!«

Sie sah so ehrlich aus mit ihren ungeduldig fragenden Augen, daß Warwara sich schämte. »Sie wußte wirklich nichts davon; es war nicht verabredet; was bin ich für ein häßlicher Mensch!« sagte sie sich, und wandte sich in herzlichem Tone zu Ruth: »Nein, kein schlimmer Grund. Klare-Bel ist so gesund, wie man es nie hat erwarten dürfen, und nun geht es stetig bergauf. Im Anfang des Winters hat sie freilich noch viel aushalten müssen. Einmal sagte sie zu mir in trübem Scherz: ›Erik muß mich mit Gewalt dazu zwingen, gesund werden zu wollen.‹ Eine Operation hat er selbst gemacht, weil die Aerzte es nicht wollten -- ohne Betäubung. ~Der~ Mann hat Eisen im Blut. Aber es hat ihn gehörig geschüttelt. Ich hab' ihn ein paarmal gesehen: blaß wie ein Tuch.«

Ruth lauschte stumm, ihre Hände verschlangen sich in ihrem Schoß, die Lippen öffneten sich halb, die Augen sagten immer nur: »Mehr!« Als Warwara schwieg, atmete sie tief auf.

»Das schrieb er nicht, daß er selbst, -- -- daß er ihr eigentlich selbst die Gesundheit wiedergegeben hat. Aber so mußte es sein! Er kann alles, was er will! Und das wollte er ~so~ aus voller Seele, daß sie wieder gesund und glücklich sein sollte. Er hat dafür gelebt. Wie grenzenlos froh müssen sie jetzt sein! Nun, wo er alles zum Guten geleitet hat! Nun, wo es ist, wie ~er~ will: ~wo sie glücklich~ ist.«

Sie sprach hingerissen; ihre Augen blitzten.

Warwara betrachtete sie nachdenklich. Sie kam ihr gar nicht mehr, wie damals, so formell abgeschliffen und gewandt vor, sondern im Gegenteil wie ein Wesen, an dem alles Beseelung und nichts mehr Form ist. Eine Seele, bis zum Rande gefüllt mit Hingebung und Gläubigkeit, -- -- und Liebe? Dann konnte sie nicht mit so kindlicher Unbefangenheit und Freude sprechen. Keine Liebe? Dann konnte sie nicht mit diesem Blick und diesem Ton sprechen.

Der Zug hielt. Sie stiegen aus.

Warwara bequemte sich dazu, eines der kleinen rasselnden Fuhrwerke zu benutzen, die am Stationsgebäude bereit standen, und deren Kutscher sie sofort umschrieen. Ruth hatte einen andern Weg. So trennten sie sich.

Warwara sah sich im Fortfahren noch wiederholt nach ihr um.

»Es ist etwas an ihr, das nicht in das Leben gehört, -- Poesie. Poesie im Konflikt mit dem Leben, -- was ergibt das wohl?« dachte sie; -- »es ist, wie wenn man die erste Seite eines Romans aufgeschlagen hätte: -- o pfui, nein! -- oder: die letzte eines Märchens.«

Ruth ging langsam hin, zwischen den kahlen Birken am Wegrande; nicht in Hast, ein paar Minuten früher anzukommen. Mit einem lauschenden Gesichtsausdruck atmete sie den Frühling um sich her ein, als ob er in tausend Blüten um sie stände. Noch war er nicht da, man sah ihn nicht, -- und doch war er da, in der Luft, in alles erfüllender unsichtbarer Gegenwart. Man hörte ihn; in einzelnen feinen kleinen Singstimmen sang er von den blattlosen Zweigen.

Der Himmel hatte sich schwach bedeckt, die Sonne schien nur in verhaltenem Glanze nieder, -- Ton, Licht, Farbe wirkten gedämpft, verhüllt, und wie eine Verheißung.

Und nun stand Ruth am alten Lattenzaun mit der knarrenden Gitterpforte. Sie öffnete, durchschritt den Garten und stieg, zaudernd, leise, ein paar Stufen zur Terrasse hinauf.

Vorsichtig vornübergebeugt spähte sie von der Seite her in das breite Fenster des Wohnzimmers, ob jemand darin anwesend sei.

Der Tisch war zum zweiten Frühstück gedeckt; hinter den Tellern mit kaltem Fisch und fleischgefülltem Gebäck dampfte der Samowar.

Jonas saß allein am Kamin. Er hielt eine lange Bratengabel in der Hand, an deren Zinken ein Brotscheibchen klebte, und ließ dasselbe an der roten Holzglut rösten. Wie er so dasaß, einen Arm nachlässig um die Stuhllehne geschlungen, in wartender Haltung, den Kopf mit den etwas zu fest geschlossenen Lippen hell vom Feuer bestrahlt, erinnerte er stark an Erik.

Das Scheibchen geriet zu nah an die Flammen; es glitt plötzlich von der Gabel und fiel hinein.

Jonas sah verdutzt aus. Er wandte sich um, und spießte ein neues auf; diesmal gelang es besser.

Dann spülte er einen Theetopf kunstgerecht mit heißem Wasser aus und machte einen Aufguß. Dabei kamen seine Finger ungeschickt genug unter den geöffneten Hahn des Samowars, und ein siedender Strahl verbrühte ihm die Hand.

Jonas machte den Mund weit auf und fing an auf einem Bein im Zimmer zu tanzen.

Vom Fenster erklang helles Gelächter.

Er blieb stehen, wie wenn ein Blitz von der Zimmerdecke vor ihm niedergefahren wäre. Mit einem ungläubigen Ausdruck, als trauten sie sich selbst nicht, richteten sich seine Augen nach dem Fenster.

Er streckte die Hände aus nach dem Bilde hinter der geschlossenen Scheibe, das ihn auslachte, und das wie Ruth aussah; er wußte nicht, ob er Ruth träumte, oder ob er Ruth sah.

Aber im nächsten Augenblick schon hatte er das Fenster aufgerissen, daß es dabei fast in Splitter schlug, und heraus streckten sich die Hände nach dem lachenden Kopf und hielten ihn fest.

»Aber, Jonas! laß mich nur erst zur Thür hineinkommen!«

»Nein, -- nicht!« murmelte er, als könne sie ihm doch noch wieder wie ein Traumbild plötzlich entschwinden, »nicht abwenden, ich laß dich nicht! Zum Fenster herein! Es muß gehen. Setz den Fuß auf die Rampe, -- ganz fest, -- hörst du? Ich hebe dich.«

Sie sah ihn an: das da sagte er nun ganz so wie Erik.

Das Klettern hatte sie noch nicht verlernt. Mit einem Satz stand sie im Zimmer.

Er ließ sie los. Er trat zurück. Nun, wo sie da vor ihm stand, nicht mehr hinter einer geschlossenen Scheibe, sanken ihm die Arme. Eine grenzenlose Befangenheit überkam ihn plötzlich.

»Wie ist es nur möglich, daß du da bist, -- von wo bist du nur gekommen?« Er starrte sie an, als sei er überzeugt, daß sie vom Himmel gefallen sei.

»Mit dem Blitzzug. Gestern abend. -- Und -- dein Papa?«

»Er müßte hier sein. Aber jetzt vergißt er die Zeit. Stundenlange Gänge macht er, allein, -- seit Mamas Abreise.«

»O Jonas, -- daß Mama gesund geworden ist, -- nicht wahr? Ist es nicht wie ein Wunder, -- immer noch?«

»Ja. Und jetzt werde ich auch Arzt. Weißt du es? Für den Fall, daß du später einmal krank wirst.«

Sie hatte sich an den Kamin gesetzt und betrachtete ihn mit freudigen, übermütigen Augen.

»Hoffentlich werde ich später einmal krank. -- -- Wie ist es dir nur ergangen, Jonas? Du schriebst nie.«

Er sah rot und verwirrt aus.

»Nie? Mir? Ja, ich mußte doch, -- ich dachte ja, -- -- Du! willst du nicht eine Tasse Thee haben?«

»Nein, danke,« sagte sie lachend; »aber die Hauptsache ist: bald kommst du nach Heidelberg, nicht wahr? Wie herrlich, Jonas. Da studieren wir zusammen.«

»Ja,« versetzte er tiefatmend, »-- endlich: -- bald! endlich! endlich zusammen! Ja, -- siehst du: lang wär's so nicht mehr gegangen. -- -- Hab' gelebt wie im Grabe,« fuhr er mit plötzlich ausbrechender Heftigkeit fort, »-- muß in deiner Nähe sein, Ruth. -- Bei dir. Ja, -- du! -- ich liebe ja nur dich. Nur dich lieb' ich, -- -- nimm mir's nicht übel, -- aber ich lieb' dich wirklich. Kann ja nichts, hab' nichts, bin nichts, -- muß mich eben erst durchbeißen, -- aber bei dir sein will ich wenigstens, -- jedem die Faust zeigen, der's auch will, -- der dir nahe kommen will! Jedem! Hüten soll er sich! Niederschlagen jeden -- --«

»Jonas! Du rasest!«

Sie war aufgesprungen, blaß vor Schreck.

Er kam zu sich, versuchte zu lächeln, einzulenken, -- und plötzlich stürzte er vor ihr in die Kniee, das Gesicht in den Falten ihres Kleides.

»Ach, Ruth! sei nicht böse! Du weißt nicht, -- es war ja so schrecklich für mich, -- all die Zeit, -- so stumm in mich hineingewürgt, alles. Sieh mich an, sei nicht böse! Nie wieder, -- es kommt nie wieder, bis --: Ich weiß, -- ich darf noch nicht. Aber einmal, -- ~einmal~ mußt' ich, -- ich wär' erstickt sonst. Ach, liebe Ruth! Ich bin ja so grenzenlos unglücklich, bis -- bis du mein -- mein -- geworden bist!«

»Jonas!« flüsterte sie, »-- Jonas, ich bitte dich, -- steh auf, -- laß mich los, -- du bist wahnsinnig, Jonas! Das kann ja nicht --«

Er klammerte sich an ihrem Tuchrock fest, den sie aus seinen Fingern losen wollte, -- er umklammerte ihre Hand, ihre Hüfte.

»Es kann nicht?!« schrie er fast drohend, und als sie sich mit einer unerwarteten Bewegung freiwand, vergrub er wie besinnungslos seine Zähne in ihren Handrücken.

Dunkel drang das Blut vor.

Sie hatte den Kopf zurückgeworfen und schwieg.

Er stand langsam auf, zur Besinnung gekommen. Er küßte ihre Hand.

»Verzeih mir!« sagte er leise und brach hilflos in Thränen aus, »Ruth -- hast du mich denn gar nicht lieb? Nicht ein kleines bißchen? Was -- was sind wir uns denn? was -- in Zukunft?«

Sie faßte ihn an beide Schultern; -- angstvoll und liebevoll sah sie ihm ins verstörte Gesicht.

»Jonas! Jetzt, -- und in Zukunft, -- und immer, -- ~Geschwister~!«

Er nahm ihre Hände von seinen Schultern, ging langsam die wenigen Schritte bis zur Thür, öffnete sie, -- und stürzte hinaus, über die Terrasse, die Stufen hinab, und verschwand im Garten.

Totenstill wurde es plötzlich im Hause. Nur die Funken knisterten und lohten hell auf im Kamin.

Ruth lehnte am Tisch und blickte nieder auf die Blutstropfen auf ihrer Hand. Langsam errötete sie, immer tiefer, bis ihr das ganze Gesicht in Flammen stand.

Was that sie hier, -- allein, -- im Hause, -- ein Eindringling, -- der Jonas hinausgetrieben?

Die Thür war weit offen geblieben. Als sagte sie: »Geh wieder!«

Ruth sah sich um. Nein, niemand sagte es. Auch Klare-Bel nicht. Nur ihr großer Stuhl stand da, mit einem hohen Schemel davor, -- leer. -- -- --

Als kurze Zeit darauf Erik die Gartenpforte öffnete, saß in der Tiefe des Gartens, den die kahlen Bäume weithin überschauen ließen, Ruth auf der Bank unter den überhängenden Birken.

Erik blieb stehen, blickte schärfer hin, und kam langsam näher. Sie bewegte sich nicht. Wie hingezaubert von seiner Sehnsucht, in den grauen Frühling hinein, so daß sie ~da~, -- in unsicheren Umrissen, -- dann immer lebenswärmer, -- immer beseelter vor seinen Augen, kein blasses Gedankenbild mehr: Wirklichkeit. Weich hob der blonde Kopf sich ab von den weißlichen Birkenstämmen und dem Gehölz dahinter, das die Sonne matt durchdrang, in einem Schattenspiel von rosigvioletten Farben.

Ruth überfiel es wie eine Schwäche, lähmend, je näher Erik ihr kam, je näher die Wirklichkeit sie umfing, die unsäglich ersehnte. »Zu Hause! jetzt erst zu Hause!« dachte sie wie im Traum, und ihre Hände hoben sich ihm entgegen.

Dieses seltsam Stille, dieses Unfähige zu jedem Ausbruch, jeder lauten Bewegung, hielt auch Erik davon zurück, -- als fürchte er zu verscheuchen, was er endlich wieder so beredt, so wortlos beredt und überzeugend vor sich sah: Blick, Ausdruck, Gebärde.

Ueber Ruths Kopf saß in der Birke ein Rotkehlchen, schaukelte sich auf schwankendem Zweig und sang hell.

Wie Erik vor der Bank stand, flatterte es erschrocken auf und flog davon.

Er hatte Ruths Hände ergriffen, er hielt sie fest in den seinen, er zog ihre Hände fest an sich.

»Lieb' -- Liebling!« murmelte er, den Blick auf ihrem Gesicht.

»Ich, -- -- der Brief, -- er machte mir angst,« sagte sie matt, »etwas Fremdes, -- Zweifel war darin. Ich mußte fort.«

Er hörte nur ihre Stimme; er mußte sie wieder hören.

»Mit dem Rotkehlchen -- hergeflogen?« fragte er.

Sie sah ihn an, -- etwas zaghaft, etwas schelmisch; »Durchgebrannt,« sagte sie.

Er setzte sich neben sie, ohne ihre Hände aus den seinen zu lassen.

»Von Römers?!«

»Ich mußte. Sie ließen mich nicht. Römer half mir. Aber sie -- sie blieb unerbittlich. Wie entsetzt war sie. ›Nur jetzt nicht!‹ sagte sie immer. Da brannte ich durch. Noch bei Nacht, -- heimlich. Telegraphierte unterwegs. Ich mußte kommen. -- Durfte ich?«

Sie fragte es schüchtern, um seine nachträgliche Erlaubnis bange, wie ein Kind. Vor Frau Römer hatte sie bittend auf den Knieen gelegen, -- aber das sagte sie nicht.

Er nahm ihr das mützenartige Barett ab und strich ihr das Haar aus dem Gesicht zurück. Ganz wiedersehen mußte er sie.

»Ob du durftest? -- ~Heimkommen~, -- ja! Bei Tag und bei Nacht; heimlich und offen. Es war Zeit. Zwei Wochen später wäre ich gekommen -- zu dir. Vergiß den Brief, -- alle Briefe, -- das Fremde, den Zweifel, -- vergiß alles -- alles. Sei nur bei mir.«

Ja, da war es: das Gefühl der Geborgenheit, süß, zwingend, Heimatsgefühl, -- nein, mehr als nur das, noch etwas andres, -- dieses Unbedingte und Ausschließliche, das keine Macht im Himmel und auf Erden ihr gab: nur er ganz allein.

»Was hast du an der Hand? verletzt? laß es mich sehen,« bemerkte er und wollte das Taschentuch lösen. Sie zuckte zurück. »Thut es so weh?«

»Nein. Nichts. Bitte nicht,« sagte sie hastig, und ein Schatten glitt über ihr Glück.

Erik stand auf.

»Komm hinein. Komm, Liebling. ~Zu Hause~ bist du erst in meinem Zimmer, -- im alten Ledersessel, -- nicht wahr? Und hier ist es noch zu kalt für dich, zu windig.«

Während sie dem Hause zugingen, sagte Ruth: »Unterwegs erfuhr ich durch einen Zufall von der beschleunigten Badereise. Ist es nicht schlimm, daß sie noch in die Schulzeit fiel? nicht in die Ferien? Mir thut es so leid, daß ich nicht mehr rechtzeitig -- --«

»Laß das,« unterbrach er sie halblaut, »-- ich werde dir später alles erzählen, -- später.«

Ruth wandte aufhorchend den Kopf nach ihm. Etwas, das sie fremd berührte, klang aus seinem Ton. Es war nur ein einzelner durchklingender Ton, aber er gehörte nicht zu Erik. Er selbst kam ihr in diesem Augenblick fremd vor. Er sah unverändert aus, -- wie vorhin, -- bis auf den Blick. Der Blick war verändert, unsicher.

Erik ließ sie unbemerkt einen Schritt vorausgehen.

Als sie die Stufen zur Terrasse hinaufstieg, folgten seine Augen aufmerksam jeder Bewegung ihrer Gestalt. Sie war ziemlich stark gewachsen, gleichzeitig hatte sich aber ihr Körper kräftiger, weiblicher entwickelt. Die dunkle Tuchkleidung zeichnete die feinen, weichen Formen ab.

Daß Ruth ihr Haar aufgenommen trug, störte ihn.

»Der Knoten nimmt dich mir fort, -- den duld' ich nicht,« sagte er beim Eintreten in den Flur, und ehe sie es gewahr wurde, hatte er mit geschicktem Griff die breite Schildpattnadel aus ihrem Haar gezogen. In dichten lockigen Wellen fiel es nieder bis zum Gürtel, wie einst.

»Ach nein, -- nicht, -- wo haben Sie die Nadel?« fragte sie verdutzt und griff nach dem Rücken.

»In meiner Joppentasche. -- Aber wiederhole das noch einmal. Nun? ›Sie?‹ oder ›Du?‹. Im Brief stand einmal ›Du‹. Nur einmal? Oder eigentlich -- immer?« fragte er leise.

Sie errötete verwirrt.

»Sie -- -- du -- -- ich --«

Die Hand noch in ihrem Haar, bog er sanft, unwiderstehlich ihren Kopf nach vorwärts, so daß sie das ganze in Glut getauchte Gesicht zu ihm aufheben mußte. Sie schloß unwillkürlich, erschauernd, die Augen und gab seiner Hand nach.

Leidenschaftlich, tiefernst forschten seine Blicke in ihren Zügen.

»Mein. Mein Fürstenkind, meine Königin,« flüsterte er.

Und er beugte sich, und seine Lippen küßten den leise bebenden Mund.

Ruth zuckte unmerklich. Er gab sie sofort frei, und öffnete die Thür zu seinem Arbeitszimmer.

»Hier wartet dein alter Platz auf dich,« sagte er und ging dem Fenster zu. Aber sie war nicht gefolgt. Dem Fenster gegenüber, am Ofen, blieb sie stehn, den Kopf mit dem aufgelösten Haar gegen die weißen Kacheln gelehnt, die Hände auf dem Rücken verschränkt. Ganz versonnen sah sie hinauf zur Zimmerdecke mit fragenden Augen und träumerischem Gesicht.

»Was ist dir?« fragte er unruhig, »-- Ruth! -- was ist dir?«

Es drängte ihn, sie in die Arme zu schließen, -- sie wachzuküssen: »Du liebst mich, -- du liebst mich ja, du weißt es noch nicht, aber ich weiß es für dich! Weiß es gewiß, -- fühle es, sehe es, daß sie da ist, -- daß deine Liebe, die Liebe des Weibes, da ist!«

Aber er schwieg.

Ja, sie war da, -- und doch konnte er so nicht handeln, so nicht sprechen, ohne sie zu verscheuchen. Sie war da, -- wie das Rotkehlchen auf dem schaukelnden Zweig, das aufflog bei seinem Nahen. Sie war da, -- aber greifen konnte er sie nicht.

Erik blickte einen Augenblick schweigend in den Garten hinaus, dann setzte er sich in den alten Ledersessel am Fenster.

»Du bist also doch nicht heimgekommen, Ruth,« sagte er, »nicht ganz zurückgekommen zu mir. Irgend etwas in dir verschließt sich vor mir, -- will mich nicht einlassen. Nicht bis in den geheimsten Winkel deiner Seele. Nicht in alles. Ich bin dir fremd geworden.«

Da löste sie sich vom Ofen, sie flog zu ihm, sie glitt nieder zu seinen Knieen, -- ganz blaß.

»Ja!« sagte sie außer sich, »-- fremd, -- etwas Fremdes, -- ich kann es nicht verstehn und quäle mich.«

»Was ist es? Sage es mir.«

»Ich kann nicht,« murmelte sie.

»Doch, doch! Du kannst. Mußt es wieder lernen, -- zu sprechen, oder auch nur zu stammeln, aus dem Innersten heraus, -- noch aus dem Unklarsten, Unverstandensten --. Es ist nur Scheu. Ueberwinde sie.«

»Es ist, -- im Kuß war es,« sagte sie leise.

»Hat es dich verletzt, -- daß ich dich geküßt habe?«

»Mich?! verletzt? mich?! nein! -- was liegt an mir?«

»-- Für mich -- alles, Ruth. -- Aber warum quält es dich dann?«

Sie verbarg ihr Gesicht in ihren Händen.

»-- Weil, -- es ist dasselbe, was im Brief war, nur in diesem einen, -- als ob er gar nicht von Ihnen kam, -- und dann: wie ich von Ihrer Frau sprach, im Garten, -- und dann: im Kuß, -- da fühlte ich es ganz deutlich, das Fremde darin, und daß es -- --«

»Daß es --?«

»Daß es nicht sein soll,« flüsterte Ruth, »weil es ist, als ob ~Sie~ es nicht sind. Ein Fremder. Ein Schlechterer.«

Er antwortete nicht.

Wie sie aufblickte, schüchtern, fragend, da hatte er die Augen geschlossen.

Nach einer Pause sagte er mit gedämpfter Stimme: »Du täuschest dich. Es ist nichts Fremdes, -- nichts Schlechtes. Ich bin es selbst, -- und in dir selbst ist es, du erkennst es nur nicht, -- mit deinen Kinderaugen.«

Er strich ihr über das Haar hin, und sah hinweg über sie, die, den Kopf unter seiner Hand gebeugt, erwartungsvoll lauschte.

»Weißt du noch, -- als du das erste Mal hier warst, -- was wir da an dieser Stelle miteinander sprachen, und was ich dir versprach? Ich wollte dich aus der Welt der Phantasie, in der du träumtest, in die Welt des wirklichen Lebens führen. Das ist damals geschehen, Ruth, und du bist nicht das Kind mehr, das träumt, sondern ein voll erwachender Mensch, der lebt, -- lebt mit allen seinen jungen Kräften. Aber weißt du, wodurch das gelang? wodurch ich dich so in deinem ganzen Wesen habe bestimmen und entwickeln können? Nur weil es einen einzigen Punkt gab, wohin sich alle vertriebenen Traumgeister, alle verstummten Märchen, alle Mächte der zaubernden und dichtenden Phantasie flüchteten. Dieser Punkt war dein Verhältnis zu mir. Da ging dein Blick noch nicht auf die Wirklichkeit, sondern, über jede Wirklichkeit weit hinaus, auf alles, was einem Kinderherzen anbetungswürdig ist. Da lebtest und gehorchtest du nicht einem Menschen, sondern einem über alle Menschen emporgehobenen Bilde, -- in deinem Innern. Aber diese ganze Traumschönheit, Ruth, in der dein Verhältnis zu mir noch steht, -- sie ist dennoch nur eine glänzende, strahlende Form, eine kindliche Umhüllung, -- nicht das Wesentliche daran. In ihr schläft, wie in einem Märchen, die dir unbekannte Wirklichkeit und Menschlichkeit und wartet darauf, daß sie erwachen darf. Erwachen aus dem Traum zum Leben, wie dein ganzes übriges Wesen.«

Er brach ab.

Sie sah aufmerksam und ernsthaft auf, bemüht, seinen Worten genau zu folgen.

»Deine schönen Märchengeschichten,« fuhr er nach einer kurzen Pause fort, »habe ich dir zerschlagen müssen, weil sie dein volles Leben aufhielten. Das schmerzte nicht sehr, denn die saßen ja nur in deinem Kopf. Wenn ich nun die Phantasiewelt

zerstören muß, die mit deinem ganzen Herzen verwachsen ist, -- und dir Schmerz damit zufüge, -- wirst du dein Vertrauen behalten, Ruth, deine Liebe -- zu mir?«

Sie versuchte aufzustehn, ein Gefühl der Angst überkam sie plötzlich. Er hielt sie zurück.

»Höre mich, Ruth. Wenn ich dir nun sagen würde: der Brief, daß der dir fremd klang, war, weil ich selbst in Zweifel und Zwiespalt und Angst war; -- daß ich dich küßte, war, weil ich nach Glück durstig war und mein Glück langer nicht entbehren kann; -- daß ich es nicht ertrug, dich von meiner Frau sprechen zu hören, war, weil -- ich keine Frau mehr habe, -- weil sie sich von mir trennen wird.«

»Nein!« sagte Ruth atemlos, »das würd' ich nicht glauben. Nicht glauben, auch wenn Sie es mir -- -- Nie und nimmer kann das sein. Kann nicht. Denn sie -- sie war ja so glücklich -- bei Ihnen.«

»Sie?« antwortete er schwer, »-- ja, Ruth, -- sie war es wohl, -- früher. Nicht ihretwegen muß es sein. Meinetwegen. Deinetwegen.«

Ruth hatte sich langsam erhoben. Auf ihrem Gesicht prägte sich ein grenzenloses Befremden aus, -- Zweifel, Unglaube, ja, Entsetzen prägte sich darauf aus. Ihr war, als müsse sie nach einem Entfernten, -- nach Erik rufen, -- ihn zu ihrer Hilfe rufen, vor einem Unverstandenen, Unbekannten. Aber er -- er war es ja gerade, der da vor ihr stand --.

Erik sah den Wechsel in ihren Zügen, die Selbstbeherrschung verließ ihn. Er fühlte nur noch Angst, -- die Angst, sie zu verlieren.

»Ruth!« rief er, »verzeih, daß du vor mir gekniet hast. Ich will es thun, vor dir. Nur sei mein! Nicht nur mein Kind mehr, -- du bist kein Kind mehr, -- ein Weib, -- mein Weib!«

In diesem Augenblick wurde die Thür vom Flur aus aufgerissen. Jonas erschien auf der Schwelle. Er trat nicht ein. Er warf die Thür wieder ins Schloß. Man hörte ihn sich entfernen.

»Jonas!« murmelte Ruth, halb bewußtlos, »-- wir müssen, -- er hat gehört, -- wir müssen nach Jonas sehen.«

Während sie es sagte, ertönte ein dumpfer Fall. Erik sprang auf. Ruth war schon bei der Thür. Sie öffnete sie.

Im Flur lag Jonas am Boden, -- lang hingestreckt. Mit dem Kopf war er im Fallen gegen den Mantelständer geschlagen. Ueber seine linke Schläfe träufelte Blut.

Ruth stieß die Mittelthür auf. Sie half Erik, ihn hineinzubringen in das anstoßende Zimmer, auf sein Bett. In den nächsten Minuten sprachen sie kein Wort. Sie waren stumm um ihn beschäftigt.

»Die Wunde ist gering,« sagte Erik nach einer kurzen Weile halblaut, -- und dann, über ihn gebeugt: »Er kommt zu sich.«

Ruth fuhr zusammen. Sie trat vom Bett zurück; ihre Augen richteten sich auf Jonas mit einem Ausdruck des Grauens, daß er sie erkennen, -- daß er sie sehen würde.

Sie machte Erik ein stummes Zeichen, und ging leise in sein Arbeitszimmer zurück.

Dort blieb sie verwirrt stehen.

Hier? Hier konnte sie noch weniger bleiben. Wo denn? Nirgends konnte sie bleiben, -- nirgends. Im ganzen Hause nicht. Sie mußte also fort. Fort, ehe Erik kam. Fort, ehe Jonas kam.

Und unwillkürlich wandte sie sich wieder der Thür zu, durch die sie soeben aus dem Schlafzimmer eingetreten war.

Nein, -- wohin? Dorthin durfte sie nicht! Abschiednehmen? von wem? Ohne Abschied mußte sie fort. Heimlich. Unbemerkt. -- Für immer?

Sie trat in den Flur hinaus, -- wie hinausgetrieben von ihren eigenen verwirrten Gedanken. Dort blieb sie von neuem zaudernd stehn.

Auf dem Boden, wo Jonas mit dem Kopf hingeschlagen war, sah man ein paar kleine hellrote Flecke. Darüber, am Ständer, hing Eriks Mantel.

Der weite, dunkle Reisemantel, den er damals trug, -- als sie fort sollte, -- und er heimkehrte, -- und als sie ihm an die Brust fiel. -- --

Ruth stand und starrte den Mantel an. Mit klopfendem Herzen und verhaltenem Atem.

Und plötzlich, da wachte es auf in ihr und riß alle ihre Gedanken mit sich fort, -- wild, glühend, unerträglich, -- das Trennungsweh.

Mit den Händen faßte sie den Mantel, sie vergrub ihr Gesicht in seine losen, weichen Falten, mit geschlossenen Augen atmete sie den schwachen Duft in sich ein, der sie an Erik erinnerte, mit bebenden Lippen küßte sie den Saum.

Damals, -- wenn er ihr befohlen hätte, ihm zu folgen, wohin es sei, wozu es sei, -- bis in den Tod, bis in das Verbrechen hinein, -- hätte sie es nicht blind gethan?

Sie drückte die Zähne zusammen; sie stöhnte, und ihr war, als müßte sie gleich laut schreien.

O Gott, auch jetzt, -- wenn er ihr befohlen hätte, ihm zu folgen, wohin es sei, wozu es sei, -- sie hätte es blind gethan! Blind gehorchend, -- gegen allen Augenschein, gegen alles eigene Wissen und Verstehen! Mit ihr durfte er thun, was er wollte. Was ihr auch durch ihn geschehen mochte, -- was lag an ihr? Er aber mußte für sie da oben bleiben, wo sie ihn gesehen, -- sein Leben und sein Haus mußten bleiben, was sie gewesen, -- an ihm lag Alles!

War er sonst noch ~Erik~?

Sie sah ihn vor sich, wie in weiter Ferne, wie er im vergangenen Mai im Mittagssonnenschein dastand, lichtüberstrahlt, die kranke Frau in seinen starken Armen. So hatte Ruth ihn zuerst mit ihr gesehen, -- so ihn geliebt und angebetet, daß selbst das Mitleid darüber verflog. »Du allzuleichte Last!« scherzte er, und Klare-Bel lachte dazu und schlang vertrauend die Hände um seinen Nacken.

Aber nun -- nun riß er ihr die Hände vom Nacken, und das glücklich vertrauende Lachen verstummte, -- und sie, die sich an ihm festgehalten, ließ er fallen, -- er öffnete die Arme und ließ sie, die Hilflose, zu Boden fallen, -- denn eine Last war sie, eine allzuschwere Last für seine Kraft. Frei haben mußte er die Arme, die sich ausbreiteten nach Ruth.

* * * * *

Ruth richtete sich auf; sie strich das Haar aus ihrem Gesicht und schlich langsam zurück in Eriks Arbeitsstube. Auf dem Schreibtisch lag ein Haufen weißer unbeschriebener Blätter. Sie beugte sich darüber und fing an zu schreiben. »Ich muß fortgehen!« schrie es in ihr. Aber Eriks Bleistift formte die Buchstaben ganz anders. So kam heraus: »Ich gehe nicht fort. Ich gehe und bleibe Ihr Kind.«

Sie blickte auf die zitternden Bleistiftstriche nieder wie auf eine fremde Schrift. Das wollte sie also thun? Ja, das wollte sie. Er hatte ja heute gesagt, das alles sei nur in ihrer Phantasie gewesen, in ihrer Einbildung, daß sie sich als sein Kind gefühlt habe, -- so ganz als sein Kind. Aber es konnte doch noch eine Wirklichkeit werden. Wenn sie es selbst verwirklichte. Es in ihrem ganzen künftigen Leben verwirklichte. Wenn sie ganz das wurde, was er sie gelehrt, was er mit ihr gewollt, als er sie zu sich nahm. Ein Stück von ihm, ein Werk von ihm. Sie hatte ja alles von ihm, -- nur von ihm allein. Sie kannte alle seine Gedanken, alle seine besten. Die sollten lebendig werden, nicht nur geträumt: gelebt. Von ihr für ihn.

Ruth nahm das Papier vom Schreibtisch und legte es auf den Lehnstuhl.

Aber trotz dieser kühnen Vorsätze war ihr gar nicht kühn zu Mut, sondern elend und hilflos. Sie hatte ein einziges namenloses Verlangen: sich auf den Boden zu werfen und zu weinen. Erik herbeizuweinen.

Aber da vernahm sie in ihrem Herzen seine Stimme, -- seinen eindringlichen, kurz überredenden Ton: »Den eigenen Willen festhalten! Haltung! Sich selbst gehorchen, -- hörst du?«

Das war doch sonderbar. Klarer, sicherer, wesenhafter denn je stand er ihr bei: Erik gegen Erik.

Leise schlich sie sich aus dem Hause.

Unten erst, an der Gartenpforte, blieb sie stehn und blickte zurück.

Nein, dafür konnte er nichts, -- Erik konnte nichts dafür, daß er anders war, und daß das Leben anders war, als sie es sich ausgedacht hatte. Im wirklichen Leben gab es nun einmal ihre Phantasiegeschichten gar nicht. Die mußte man erst hinzuthun.

Und hatte sie alles das nicht nur geträumt, -- das ganze verflossene Jahr? Wie sie so dastand im Sonnenschein und Vogelsang, da mochte es ihr wohl scheinen, als sei sie zurückgekehrt zum vergangenen Mai, wo sie bange und allein, arm und einsam, hier an der Pforte lehnte und in den Garten sah. Damals meinte sie: von hier ginge der Frühling aus, der ganze wunderschöne, der draußen blühte. Und da träumte sie sich ein Märchen, das »allerschönste von allen«.

Ja, das allerschönste von allen.

So schön, daß sie es nie wieder vergessen konnte. Nein, niemals.

So schön, daß sie es nie hergeben konnte für etwas andres, was ihr das Leben bot. Niemals.

So schön, daß es nichts mehr geben konnte, -- im ganzen Leben nichts, -- was sie nicht immer daran messen, immer damit vergleichen, -- und zu gering befinden würde.

* * * * *

Ruth öffnete die knarrende Pforte und trat auf die Straße hinaus. Ohne es selbst zu wissen, hob sie ihre Hand und strich leise, liebkosend über die kahlen harten Fliederzweige hin, die den Zaun in dichtem Buschwerk umwuchsen.

Dann ging sie, ohne sich noch umzuwenden, mit gesenktem Kopf den Landweg zwischen den Birken zurück zur Station, und ihr langes loses Kinderhaar flatterte im Frühlingswinde. --

* * * * *

Erik stand noch bei Jonas am Bett. Jonas hatte die Augen aufgeschlagen, den Vater neben sich erblickt, war zusammengezuckt und hatte von neuem die Augen geschlossen. Kein Wort fiel zwischen ihnen.

Erik begriff nun den ganzen Zusammenhang, begriff vieles, wofür ihm wohl eher das Verständnis hätte aufgehen müssen, wenn er Gedanken dafür übrig behalten hätte. Der atemlose Fleiß von Jonas, seine Begierde nach Selbständigkeit, sei es auch im engsten Leben, -- dieser Anstrich von Philistrosität, diese Abkehr von aller fröhlichen Unbesonnenheit und Thorheit wurden Erik jetzt verständlich. Nicht Mangel an Temperament, an Jugendfeuer war das gewesen, -- sondern eiserne Ausdauer, Selbstbeherrschung.

Kinderei oder nicht, -- es lag Kraft darin. Er achtete seinen Jungen.

Aber der -- -- achtete ihn nicht.

Jetzt, in dieser Stunde nicht. Ein ganz neues Verhältnis zu seinem Sohn, ein ganz neuer Kampf erwartete Erik jetzt, und er mußte nun seine volle Kraft zusammennehmen, um darin zu siegen.

Ein leises Knaben der Gartenpforte weckte ihn aus diesen Gedanken. Bei dem kaum hörbaren Geräusch durchblitzte ihn ein plötzlicher Schreck.

Er öffnete die Thür zu seinem Arbeitszimmer. Ruth war nicht darin. Er ging über den Flur in das Wohnzimmer. Ruth war nicht da.

Erik stieg in den Garten hinunter. Eine furchtbare Beklemmung drückte ihm die Brust zusammen.

»Ruth!« rief er laut, und erkannte seine eigene Stimme nicht.

Alles blieb still. Es blieb still, wie weit er auch hineinging, bis an die Bank vor dem Gehölz.

Nur ein Rotkehlchen saß auf dem Birkenzweig über der Bank und sang.

Es ließ sich nicht einmal durch die Menschenschritte schrecken; ganz regungslos saß es da, mit erhobenem Köpfchen, ganz selbstvergessen, -- und sang und sang in den grauen Frühling hinein --.

PREFACE.

Every effort of human ingenuity professing to remove or lessen pain and inconvenience, is, naturally enough, hailed with approbation, and the public require not so much to be aroused to estimate fully the advantages proposed, as to be guarded against implicit belief and heedless confidence in the value and importance of the remedy. It is, however, of the utmost importance to be accurately informed what kind of benefit we may fairly expect from the use of the given means, and to what extent this benefit may be obtained; and yet the man who steps forward to state this plainly and fairly, too often fails of the success which his undertaking deserves. Experience proves that such endeavours have been contemned by some, looked upon with cold indifference by others, and viewed with suspicion by nearly all. We are too apt to suspect interested motives, to doubt the sincerity, and undervalue the abilities of men, who have devoted their lives, and the force of their talents, to a particular pursuit; and then, as though this cunning incredulity was closely allied to implicit credence in the wildest chimeras, we become ready listeners, and passive victims, to pompous and plausible charlatans, who make the largest promises, alike indifferent to the practicability or usefulness of their specifics. “It is a great mistake,” said an able English statesman of the last century, “to suppose men harmless because they are blockheads; the dunce thinks neither of country nor of consequences in the pursuit of his petty interests and passions, which may, and often do, lead him to work the greatest public calamities.”

I have refrained from advancing any crude theoretical opinions, which might fairly be questioned. The information conveyed in these pages is of a practical character; has stood the purifying test of time; and, being based upon the immutable principles of optical science, courts every enquiry and challenges all investigation.

My object has been to provide the public with a compendium of sound and standard information on this most interesting and essential subject, in order that, possessing themselves of the truth, and becoming conversant with the real merits of the question, they may no longer be the victims of ignorant, designing, and knavish speculators, who so mercilessly practise on their credulity. I have freely availed myself of facts and observations with which I have become familiar in the course of my own experience and connexion with an establishment of more than one hundred years' standing, and, at the same time, have endeavoured to condense in one publication the essence of many voluminous treatises.

"It is only by condensing, simplifying, and arranging in the most lucid manner possible, the acquired knowledge of past generations, that those to come can be enabled to avail themselves to the full of the advanced point from which they will start."

I have only to add, that though I would not desire to offend the critical acumen of any of my readers, yet, having but little leisure, and those moments of rest being snatched from the busy whirl of commercial pursuits, I have been much more anxious to give solid information in language universally understood, and divested of technicalities, than to employ nice set terms, chosen to please the critic's curious ear.

GEORGE COX.

The first edition of this work having found a ready sale, spite of all the opposition and abuse lavished against it by the itinerant _opticians_, I have reprinted it with such improvements as the kindness of friends and my own experience have suggested.

128, HOLBORN HILL, LONDON, _January, 1844_.

Reviewers' Opinions of this Work.

"The information which this little book contains is really very good and very applicable to the instruction both of the short-sighted, who never reflect before they buy, and of the very long-sighted, who, from excess of cunning in the search of great bargains, are, like our friend Moses in the Vicar of Wakefield, open to very _gross_ impositions in the matter of spectacles and their very _chagrin_ cases. Those who are not opticians or oculists will do well to read the book before they commit themselves in the purchase of glasses either from itinerant or stationary quacks. But this is not all: though a simple monograph of the frauds of one trade, the book may be generalized into "a manual of the whole art of puffing," and an exposure of the silly credulity of the public in all its branches. Mr. Cox also discloses some of the machinery of newspaper puffing in a way which almost tempts us to claim it as "our thunder," it is so much in unison with our published opinions on the subject."

Athenæum.

"In this well-written work Mr. Cox has given a popular description of the eye, and the adaptation of spectacles to correct constitutional defects or organic disease: by attention to a few simple rules which he lays down, any one may effectually fortify himself against the artful representations of dishonest dealers in spectacles "made to sell." The public is indebted to Mr. Cox for having exposed the tricks of the insidious marauders in several towns in which they were practising their impositions, and his tract contains some correspondence between him and several eminent surgeons, from which it appears that they had been represented as vouching for pretended improvements in spectacles, of which they either knew nothing at all, or with regard to which they themselves had been deceived by the fraudulent pretenders."

Christian Advocate.

"This is a useful little work, treating on a subject of universal importance—namely, defining the laws by which deficiency of sight can be assisted, founded on scientific principles, and aided by extensive observation in a long practice; we would recommend a perusal of the pamphlet to such as are about to seek the aid of the maker of spectacles."

Morning Advertiser.

"This little _brochure_ is correct, ingenious, and useful: moreover, it is valuable as exposing the gross ignorance, impostures, and frauds of Jews, pedlars, and other locomotive quacks. The humbug of _amber_ spectacles, _coloured_ pebbles, clarified crystals,

&c., is here thoroughly exploded. Altogether the information in this pamphlet is well deserving of attention."

Aldine Magazine.

"An amusing exposure of the puffing and swindling systems pursued by some self-styled opticians, from which besides may be gathered a good deal of sound, practical information."

Era.

"If every body's sight were impaired, we should strongly hope that this little treatise would become universally known; but as we have reason to believe there are some people in the world who can see a little, we shall only address ourselves to the former, to whom we can confidently recommend the perusal of this talented work. Besides a great deal of necessary and sound information on the use and nature of spectacles, we find a number of _exposés_ of the tricks pursued by many unprincipled persons styling themselves opticians, which is put forth by the author in a very distinct manner."

Blackwood's Lady's Magazine.

SPECTACLE SECRETS.

CHAPTER I.

“Science should be stripped of every thing that tends to clothe it in a strange and repulsive garb, and especially every thing that, to keep up an appearance of superiority in its professors over the rest of mankind, assumes an unnecessary guise of profundity and obscurity, should be sacrificed without mercy.”—SIR I. F. W. HERSCHEL.

Spectacles and side-saddles, we are quaintly informed, became common in England in the reign of Richard the Second. The ancients, however, knew the power of burning-glasses, and one cunning rogue, we are told, discovered a new way to pay old debts, by means of a round stone or glass used in lighting of fires, with which he melted the bond, written, as usual in those days, on wax. Their burning glasses were spheres, either solid or full of water, their foci were consequently very short and confused. A long interval occurred before spectacles were constructed, and three hundred years elapsed between the invention of spectacles and telescopes.

Our eyes should have our nicest and most tender care, since it is by them we are familiarized with objects of the most exquisite interest and beauty, abounding on the earth we inhabit, and in the starry firmament above us:—

“My soul, while Nature’s beauties feast mine eyes, To Nature’s God contemplative shall rise.”—DODSLEY.

The faculty of sight should be estimated and regarded by us with more than ordinary care, when we reflect that it is the medium through which the most exalted and gratifying impressions are received; and our watchful regard to its healthful preservation and agreeable exercise is the more required from the consideration, that while to its admirable organization and delicate sense of perception we stand so much indebted, those very qualities render it extremely sensitive to injudicious treatment.

It would be a wholesome, fair, and proper regulation, to restrain all from practising as opticians but those practically conversant with the production and application of lenses for the purpose of aiding the exercise of sight. It is considered indispensable for the surgeon and medical practitioner to prepare for his profession by a course of study, reading, and practical operations, and to be subjected to an ordeal where his capabilities are examined and tested. Such an arrangement, though it _may_ sometimes be abused, guarantees to us practitioners who understand their duties; and thus are the many “ills which human flesh is heir to” alleviated and subdued, while those unfortunates who are practised upon by the empiric and miracle-monger, have their calamities aggravated, and their sufferings increased.

It is a question often mooted, how far it is the duty of a just and equal government to interfere in such cases for the protection of its subjects: this, however, is evident, that whatever restrictive laws are framed, if they are attempted to be enforced while a want of information prevails upon the subject, the very people for whose benefit and protection they are introduced, will, likely enough, view them with distrust and suspicion, and, until the imposition has been unmasked, will look upon those who have assumed characters not their own, as persecuted individuals, entitled to their sympathy rather than their detestation. It is by diffusing information, and clearing away obscurity, that we shall erect the best safeguard against delusion. Those who are ignorant are consequently credulous, superstitious, and undefended against the tricks and subtleties of the artful and designing.

If a book is published, our opinion is almost insensibly influenced by what the reviewers say of it. If a new association, a company, or enterprise of any kind is projected, we look to the list of directors, committee, and patrons. Our education and universal custom induces us to pay deference to those whom we suppose to be possessed of superior information, to be men of character and reputation, and entitled, from their position in society, to be regarded with respect.

These legitimate feelings have been so poisoned and tampered with by those who have designedly entered into a conspiracy to hoodwink the people, and share the plunder; and again by the hardly less criminal apathy of others, who, without dividing the spoil, have suffered the trickery to pass unexposed; that professional and literary men cannot but perceive distrust and want of confidence in their decisions, now becoming general among the reflecting and intelligent classes of society, who see that they have been trifled with, and treated as credulous dupes, and that they really have no guarantee for the merits of a production, the purity of a proposal, or the honesty or propriety of any measure to which distinguished names and lofty patronage are appended. The exposé of the practices of the railway, mining, and other bubble schemes illustrates this truth; and the secrets elicited during the discussion on Mr. Serjeant Talfourd’s Copyright Bill, clearly demonstrate how infamously the confidence of “a generous public” has been abused.[1]

The great and benevolent men who existed before us, and devoted their time and contemplations to the interesting science of optics, have fully and clearly demonstrated the laws which regulate the action of light, the cause and effect of luminous phenomena, and the principles upon which vision depends. We have the conclusive and unvarying results of their numberless experiments, performed under every modification of circumstances, to guide us in establishing principles and rules of action, which the studious and practical opticians of our own times have tested, and, ascertaining them to be free from error, now adopt and act upon them.

The captious and consequential may complain of this admission, as tending to detract from the importance with which they might otherwise be regarded; but the optician, who deserves that name, is not anxious to array himself in borrowed plumage, nor to appropriate as his own that which rightfully belongs to others. Granted that we act upon settled and incontrovertible philosophical principles, is it not infinitely more gratifying to have the assurance of a correct result, than to be for ever experimentalizing without arriving at a satisfactory conclusion? The skilful surgeon and the talented engineer are guided in their operations by certain fixed and universal laws, yet no one will dispute that to perform the duties of either of those professions requires much application, skill, and expertness. Precisely so with the optician of the present day. He has fixed, universal, and certain data for his operations; and it is upon his intimate knowledge of these, and the careful and judicious application of them, that his success depends.

When the healthy powers of vision begin to fail, we feel a tender and anxious concern to perpetuate the enjoyment we find to be so intimately dependent upon the uninterrupted exercise of sight, and are instinctively led to seek for a remedy. Much mischief will be avoided, and misapprehension removed, if we consider that in applying artificial aid to the eye, we have to do with one of our most sensitive and easily deranged organs. The human eye is composed of a series of humours and membranes: the outer coating, called the _sclerotica_ (_a_), see _Plate, Fig. 1_, is exceedingly strong, and the muscles which move the eye are attached to it; the white of the eye is a portion of this coating. The _cornea_ (_b_) arches out or projects from the eye-ball; it is transparent, and of a circular form. The next coating to the sclerotica is called the _choroides_ (_c_); it has no muscular motion except at its extremities, near the front of the eye. The _iris_ (_d_) is next apparent; it attaches itself to the sclerotica by a cellular substance called the _ciliary circle_ (_e_). According to the colour of the iris the eye is termed black, blue, hazel, &c. It is composed of two sets of muscular fibres, the one tending, like radii, towards a centre, the other forming a number of circles concentric with the same centre. The aperture in the iris is called the _pupil_ (_f_); it is always round, but varies in diameter as the radial or the circular fibres of the iris are contracted or expanded, according to the quantity and quality of light it is required to admit, acting like a watchful centinel to regulate the amount of rays requisite to transmit a perfect and well-defined image of objects onwards to the brain, which, without its agency, would appear one undistinguishable mass of confusion. The chamber of the eye is darkened by the posterior surface of the choroid membrane having a lining of dark-coloured mucus, called the _pigmentum nigrum_. The last coating of the eye is the _retina_ (_g_), a delicate and most important membrane in the construction of this noble instrument; it is an expansion of the _optic nerve_ (_h_), directly emanating from the brain; and is spread like a net of exquisite delicacy all over the surface of the choroides, terminating at the ciliary ligament. It receives the images of objects by means of the rays of light that enter at the pupil; it is transparent, but appears black on account of the dark pigmentum behind it. The optic nerve passes through a small aperture in the “_architectural dome_” containing the eye, and it conveys the impressions made on the retina into the depository of the brain, where the “very form and spirit of the scene is now conceived.” It is situated a little on one side of the centre of the eye, inclining towards the nose.

To describe more minutely the various fibres, humours, and ciliary processes of the eye, or to enter more fully into its anatomical arrangement, would be incompatible with the design of this publication, which is intended for the “general reader,” and therefore so simplified as that it is hoped he cannot fail to understand. The three transparent humours enclosed by the coats of the eye, viz., the _aqueous_ (_i_), the _chrystalline_ (_k_), and the _vitreous_ (_l_), are, however, too important to be passed over without some notice. The aqueous (_i_) humour it is which gives a protuberant figure to the cornea (_b_); it has a refractive power, similar to that of water, which it also resembles in appearance. The chrystalline (_k_) humour is more transparent than the purest chrystal; its form is that of a double convex lens, which it also resembles in its use, as it converges the rays which pass through it, from every visible object to its focus on the retina. It is suspended in a fine transparent sheathing. The shape or convexity of this natural lens alters occasionally, and shifts a little backwards or forwards in the eye, so as to adapt its focal distance from the retina to the different distances of objects. The vitreous humour is situated at the back of the chrystalline, filling nearly three-fourths of the globe of the eye; it is surrounded by a thin capsule, which sends off a number of membranous processes into the vitreous substance, where they form cells, which, communicating with each other, give a high degree of firmness and tenacity to the whole.

Fig. 2. represents the eye at the time when spectacles are required, the cornea, or the chrystalline, or both, having lost a part of their natural convexity, consequent upon age or constitutional weakness. An object placed at the same distance from the eye as in the perfect eye, (_Fig. 1_), has the focus carried beyond the retina. A convex lens applied to the eye compensates for this loss of capacity, and, converging the rays, corrects the focal distance, and the image is now imprinted naturally on the retina. The reverse of this takes place in the case of the short-sighted; the humours being _more_ convex than in the perfect eye, the rays converge in a focus _before_ they reach the retina. A concave lens carries the focus further on, and, by its aid, an object will be depicted perfectly on the retina.

No. 4 represents a plano convex lens—5, a double convex—6, a plano concave—7, a double concave—8, a periscopic or meniscus lens.

What grandeur and sublimity of contrivance is here blended with simplicity of action and power of expression! How indispensable to a full appreciation of the bounties of nature and the beauties of art by which we are surrounded! To be deficient of this heavenly gift is truly to have “wisdom at one entrance quite shut out.”

Surely every consideration should influence us to treat this invaluable faculty with judicious care, instead of allowing it to be tortured and trifled with by the ignorant and unprincipled.

Having surveyed the general construction, and glanced at the inimitable mechanism of those windows of the soul, we shall be better prepared to understand the reasoning, and to comprehend the principles upon which the science of optics is based. Those of my readers who have leisure to pursue this subject, will find new light, and more convincing illustrations attend their enquiry at every step. It is a subject abounding in beauty and interest, introducing us to new regions of sublimity and grandeur, where the contemplative mind will assuredly find “ample scope and verge enough” to gratify its most exalted anticipations. We have seen the admirable, yet at the same time delicate contrivances by which the functions of the eyes are performed. It cannot fail to have occurred to us, that a machine so beautiful and complete is liable to derangement and improper treatment by the wayward and the ignorant. If it is desirable that a person possessed of a well-constructed watch should understand its general action, and know what treatment it should have to keep it in sound and underanged order, still more essential is it that every individual should possess a clear and familiar knowledge of the nature of vision, and understand the requirements of the eyes. I cannot forbear indulging a sanguine hope that the circulation of this little manual will open the eyes of its readers to the simple facts of the case, and animate them to think and judge for themselves, instead of giving a ready ear to the marvellous and ridiculous tales, which, though, like the sailor’s tough yarn, so often told that the cheat believes them himself, are nevertheless utterly devoid of truth.

FOOTNOTES:

[1] In the month of August, 1838, the solicitor to the Duke of Wellington waited upon Sir Frederick Roe, at Bow-street, in reference to the use which had been made of his grace’s name by “The London Equitable Loan Company.” A gentleman, who was desirous of purchasing shares in the company, seeing the Duke of Wellington mentioned as patron, and that the account of the company was kept with the Bank of England, wrote to the Duke to ascertain if it were true that he was connected with the concern? The duke never had consented to become a patron, but, on the contrary, when asked to do so, answered that he was so situated that he could not comply with their request. On receiving the communication the duke wrote to Sir F. Roe, to see what could be done to guard the public against any transaction which might be entered into in consequence of the use made of his name; and in answer to a letter written by him to the Bank of England, he was informed “that no such company was known there, nor had they any account of the London Equitable Loan Company.” The publicity given to this manœuvre has no doubt saved many a family from enthralment and destitution.

CHAPTER II.

“The subject is of universal importance, since every man, woman, and child in the empire will probably require optical assistance.”—ABBOTT.

The eyes, when in a sound and healthy state, instinctively adjust themselves at a distance of twelve inches from a book or paper, when they are observing the same. This distance is found to be most natural and agreeable; for when we extend it to sixteen, twenty, or thirty inches, the chrystalline lens is stimulated to keep a distinct and clear perception, until, as the distance increases, the object becomes less and less perceptible. When we are compelled to extend this natural distance, experience difficulty in reading small characters, or find it necessary to get more light on what we are observing, we may safely conclude that artificial assistance is needed, and that, judiciously applied, the tendency to decay will be mildly arrested.

The design of spectacles is to supply the loss of power which is experienced by the eyes at different periods of life, and arising from various causes. These productions of art are constructed with a close observance to, and act upon, the same principles as those by which the process of vision is regulated.

Spectacles ought not to do more than maintain or preserve to us the capability of seeing at the natural distance. This is, in fact, all they are intended to effect. When the chrystalline lens of the eye, losing its convexity, fails to converge the rays of light, and bring them to their natural focus on the retina, an artificial lens, of suitable convexity, supplies to it this capability, and compensates for its gradual diminution of capacity. Thus lenses for assisting the sight are fashioned upon the optical principles so apparent in the mechanism of the eye itself, which, it will be observed, is neither round nor flat, but of that nicely moulded convexity which is indispensable for the performance of its functions. If lenses were either spheres or planes they likewise would be ineffective for the purpose proposed.

There is not any material in existence beside pebble and glass, which is calculated for spectacle purposes. The pretended “improvements,” “pellucid lenses,” “refractive transparencies,” “patent amber,” “chrystal preservers,” &c., are new-fangled terms, coined to entrap the uninitiated.[2]

Convex lenses are produced by a series of operations through which a glass or pebble passes, as shaping out from the rough piece, affixing them to the block or frame on which they are worked, grinding their surfaces to the form and focus required, in brass or iron tools of the curvature or radius corresponding. Thus to produce a glass or pebble of any given focal length, we use a tool which is a portion of a sphere or globe of four, five, ten, or any other given radius, or half its diameter. For spectacles usually required, the focus of the pebble or glass, thus fashioned, varies from sixty inches down to five inches. The focus of a convex or magnifying glass is ascertained very readily, thus: hold the lens near to a white surface, as a sheet of writing paper, pinned to the side of the apartment opposite to the window; shift the lens gently backwards and forwards, until the objects before it, as the window frames, flower pots, or the Venetian blinds, are seen inverted upon the paper, clearly and distinctly measure the distance from the paper to the lens, and this distance is the focus: or, by placing a candle at the distance of twelve feet from the paper, and measuring, as before, when the reflected image of the flame is shown most accurately on the paper, we again have the focus denoted. The one method is as much practised as the other; though, in ordering a lens of a given focus, I would recommend a person always to state the method by which he has determined the focus; whether by the sun, or candlelight, which will prevent any mistake arising from the disparity between the two plans pursued.

Concave lenses are made upon the same principle, and pass through similar processes. They are designated by numbers, thus: a concave lens, worked in a tool of four-inch radius, is termed No. 12; five-inch, No. 10; ten-inch, No. 6. &c.

To determine the radius or focus of a concave lens, apply to its surface a convex lens of the same focus, and holding the two together as one glass, between the thumb and finger, at some distance before the eye, give the hand a gentle motion to and fro, and if the objects looked at through the lenses now in contact appear fixed, equal, and of their natural size, then is the focus of the one correspondent to that of the other; but if the convex lens is not of the same focal length as the concave to which it is thus applied, then all objects looked upon will appear to shake and have a tremulous motion.

Another method of ascertaining whether one concave lens is of the same number, and worked in tools of the same radius as another, is to hold one in each hand, placing their edges against each other, with their centres in a parallel line; now withdraw ten or twelve feet from the window, and observe the top and bottom bars of a square of glass: if they appear equal and uniform in all their parts, parallel to each other, and agreeing with the other squares in the window, then are they of the same radius; but if they do not match, the bars will appear disjointed, and higher or lower in one square than in the other. The trial box of sights will be found very useful in making these experiments.

Brazil pebbles, or crystallized quartz, are imported to this country in rough blocks; these are cut or slit, by the aid of pulverized diamond, into slabs or pieces, of the diameter required. Those pieces in which bubbles, waves, or blemishes appear, are thrown aside by the optician who is tenacious of his fair fame, as their imperfections become more apparent in every after-stage of their progress; and when polished, centred, and shaped for the spectacle-frame, they are really improper to be used at all; nevertheless, the needy, or dishonest, rather than lose a fraction of their gains, often persist in working up such imperfect material, and harping upon their being pebble—real pebble—palm them off upon the uninitiated as genuine articles. Pebbles have the following important advantages: they are of equal density, and exceedingly hard, firm, and clear; their surfaces are not liable to become misty or scratched (which circumstance alone often compels a change of glasses): they are of a pure, cool nature, and shew this contrast to glass (which is, on the contrary, produced by the action of artificial heat) in the touch of the finger or tongue to their surfaces.[3] They are, in consequence of these properties, calculated to suit the sight for a longer period than glass; but they need not be thrown aside, when, from the indications already referred to, we find an increase of magnifying power is required, as they can be re-worked readily enough to meet the requirement of the eyes, and at an expense scarcely more than a new pair of glasses, or about one-third of their original cost. The directions for ascertaining the focus of concave or convex pebbles, are the same as described for concave or convex glasses.

This consideration should weigh with those who are apt to be misled by the pretensions of the unprincipled; for pebbles have, in common with many other crystals, a double refracting property, which, if the pebble is cut carelessly, exhibits itself by painfully affecting the vision; two objects, instead of one, are seen, causing a confused and agitating sense of indistinctness, which, in proportion to the exertion of the eye to overcome it, is the more tiresome and distressing. Such faulty and blemished articles, technically called _wasters_, are refused by the optician of any real respectability and character, but are eagerly bought up by those venders, whose object is to purchase what costs them the least money, alike ignorant of, and indifferent to, any other consideration.

Pebbles, therefore, like all the precious stones, which, in fact, are crystals, cannot be properly cut or sliced except in a parallel direction to their natural faces.

Periscopic or meniscus lenses were introduced in the year 1770, and revived at a later period by Dr. Wollaston. Their properties were investigated by many scientific persons, and again candidly examined by Mr. W. Jones; yet, notwithstanding the oblivion to which they were consigned by the universal consent of practical opticians, they are still foisted on the public, under various disguises, and embellished with sundry new appellations. They are concave on one side, and convex on the other, the inner and outer curve differing, in order to produce a focus. When placed in the spectacle-frame, their convex surface is always from the eye; this necessarily exposes their centres to be rubbed and scratched. The halo, or aberration of light, is greater in lenses of this form than in any other. This can be easily proved by placing a double convex, and a periscopic lens, each of the same diameter and focus, say one-and-a-half inch diameter, and three or four inch focus, edgeways together. Let the image of a lighted candle be thrown against a white wall or paper, in a dark situation, through the two lenses, and it will be conspicuously seen that the periscopic lens exhibits this dazzling indistinctness, while in the double convex lens it is scarcely perceptible.

Parallel or flat surface lenses are produced from tools perfectly level, and without any curvature. For spectacle purposes their only use is as shades or shields for the eye, to protect it from the effects of bright and dazzling objects, dust, and wind. They are, however, indispensable in the construction of sextants, artificial horizons, and other mathematical instruments.

Spectacles for travelling by rail-road, on the old beaten path, or by vessels, are usually fitted with parallel glasses, unless the wearer requires focal power as well as a screen, in which case they are of the concave or convex figure, before explained. Almost every combination of light and shade has been used for this class of spectacles; violet, grey, blue, green, crape, wove wire, &c.; but some sensitive and tender eyes failed to receive the relief expected from any of these, and opticians have been repeatedly baffled in their attempts to produce a shade of glass congenial to the requirements of the eye under such circumstances. I have made extensive use of the new neutral tint, or twilight tinge glass, and find it most agreeable to the eye while employing it, and when removed, it leaves the vision undisturbed by the flickering and confused halo so much complained of after wearing other coloured glasses. The cause of this superiority is clearly seen when we remember that, after taking off a pair of green glass spectacles, every object appears of a red colour, while, upon the removal of blue colours, an orange or yellow mantle seems to rest on all which meets the view.

It is of consequence that all such glasses should be really parallel, otherwise a broken and disjointed appearance will be given to objects, the rays of light being abruptly dispersed instead of being transmitted through the transparent medium to the eye, in their natural direction. I have always discountenanced the use of wire, gauze, crape, and muslin substitutes for glass, because, in my opinion, it is a fallacy to assert that they are cooler and more agreeable to the eye. There is abundant space for the circulation of air in the region of the eye if the spectacle-frame adapts itself pleasantly to the wearer’s face; while the eye and common sense may answer together, that to look on things around us, a transparent medium is preferable to a hazy and indistinct one. We do not choose bars and gratings, or coarse curtains, in preference to glass, for the windows of apartments; but if the light is sometimes too intense, we place a shade to soften its dazzling effects. Such precisely is the reason why tinted glass spectacles, for defending the eyes from rain, dust, and wind, are recommended.

Lenses worked by machinery are produced in greater quantities, within a given time, than those worked by hand. They are passed through the different stages of grinding and polishing without having the keen eye of the workman carefully watching their progress, and adjusting the inequalities in their surfaces or edges, which will always appear more or less in the course of working.

The price at which competition demands those lenses shall be rendered, operates against the wearer of spectacles; for the producer cannot afford to throw aside such as are faulty, and the wholesale agent and retail dispenser cannot expect to have, at the low price charged, lenses which will bear a critical examination; and thus all which can possibly be used are thrust into frames of one kind or other, from the common iron or horn sold by the poor hawkers at sixpence, eightpence, and one shilling per pair, to the more expensive frames; while many faulty glasses, after being dubbed with some ear-tickling appellation, and imbibing extraordinary “light-modifying and refractive virtues,” by passing into the hands of the hawker of a higher class, are palmed upon the unfortunate spectacle-purchasers who are simple enough to give credence to the wondrous tale.

Women and children are chiefly employed to cut and edge those cheap glasses to the spectacle-frames; and who can expect they should do them better for the price? And if one glass should be unequally thick, like a wedge, while its companion in the same spectacles is miserably thin; or if the centres, instead of being equidistant from all parts of the rim are nipped into a corner; how

can you feel surprised when you consider that for them to earn a living, it is necessary they should finish several dozen pairs per day, and therefore, expedition, rather than excellence, is the point at which they aim? In many departments, where machinery has supplanted manual labour, the work produced is of a superior character, and will bear more critical examination; but the contrary is the fact in the case of machine-worked optical glasses, and is more especially apparent in such as are intended for microscopic and achromatic purposes. It cannot be denied that, for all such uses, lenses worked by hand, with the ordinary care of a skilful workman, as much excel those produced by machinery, as the accurate and scientific touch of the artist eclipses the random splash of the plasterer.

The trial box, or frame of sights, ranging from the slightest focal power down to the deepest, is a very useful apparatus, both for the optician and his patient. It consists of eight or nine spectacle-fronts, clamped together at one end by a rivet, on which they are yet free to move. The focus of each pair is stamped on the front. They are enclosed by a pair of lids, which forms a handle, to be held by the hand, while one front after another is placed before the eyes, to determine what focus yields the desired assistance. This being ascertained, and having noted down the power we find to suit most naturally, as explained when treating of convex lenses, page 12, we have only to determine what style of mounting we prefer, and whether we will have glasses or pebbles, for the optician to suit us at once with lenses adapted to the sight, and mountings fitting pleasantly to the head. If an interview with the optician is impracticable, it will be ensuring greater accuracy, to mention the exact distance, measured as a straight line from the centre of the pupil of one eye to that of the other; and if the nose, on the bridge between the eyes, is flat or prominent, broad or narrow, since spectacles, suiting the sight most accurately, are frequently an annoyance, rather than an assistance, to the wearer, from these particulars being unheeded.

Two trial boxes comprise the range of convex sight, one for young persons, and those who require spectacles for the first, second, or third time; the other for those eyes which have been long accustomed to spectacles, or from some constitutional or sudden cause, need those of strong magnifying power. The third box contains concave lenses, ranging from No. 1 to 12, which are the sights chiefly wanted, although, in extraordinary cases, No. 13, 14, and even 20, have been required.

Although, throughout this treatise, I have endeavoured to convince my readers that they may and ought mainly to determine for themselves, yet I would recommend a visit to the optician, where it is practicable, in preference to a description of the case; for the same reason that the best written statement of a patient's malady, sent to a physician, does not afford him that familiar acquaintance with the case which an interview of a few minutes would supply.

FOOTNOTES:

[2] The manufacture of glass was known very early, but glass perfectly transparent and colourless was reckoned so valuable, that Nero is said to have given a sum equal to £25 for two moderate sized colourless drinking glasses.—_Starke's Oriental Letters._

Glass for optical uses is heavy, homogeneous, free from streaks and veins. More expensive chemical substances are employed in its manufacture than are used in making common glass.

[3] Pebbles, again, are proved by grinding the edges briskly on a moderately smooth file, or porous stone; they will resist the action of these, and emit sparkles of light as the velocity of the friction is increased, while glasses, on the contrary, yield, and are ground without difficulty.

CHAPTER III.

"Every day's observation shews how far some men may be carried from the most evident and obvious truths, to support a new hypothesis, which has no foundation either in nature or reason; but truth will ever control and prevail over error, though supported with all the powers of rhetoric and novelty."—B. MARTIN.

Where distance, or any other cause, prevents our having access to persons who are competent to suit us properly with spectacles, great care should be exercised to choose those which cause the print of a newspaper, or the ordinary types of a book, to appear of their natural and proper size, while they are viewed at the distance most agreeable for reading, viz., twelve inches from the eye. It is evidently better to "try spectacles" on such ordinary printing as they will be generally exercised upon, than to test them by the very small print with which persons frequently provide themselves. To decipher this, a greater power is demanded than is requisite for usual reading, writing, and needlework, which are the purposes for which we require them, and not for microscopic observation, nor for distant views.

The eyes in which no malformation or disease exists, but which simply partake of constitutional decay, or, from too continued application to sedentary and studious pursuits, are beginning to feel a want of assistance, should have spectacles of sixty-inch focus, which is an exceedingly slight magnifying power; and if these are found to be insufficient to afford an agreeable and natural perception (not an enlarged or magnified image of the letters of a book, &c., held in the hand at the distance of twelve or fourteen inches from the eye), then apply those of the next power, viz., forty-eight inches' focus. If these again are unequal to supply the loss of power or incapacity of the eye to converge the light to a point at the instant it reaches the retina, then lenses of thirty-six inches focus are to be had recourse to; and when these fail to afford agreeable vision, thirty, twenty-eight, twenty-four, twenty, must be progressively adopted, thus gradually descending the scale until the eyes receive such compensation for their progressive decay and loss of power, as spectacles carefully suited to the sight are capable so effectually to supply.

The period at which the sight begins to fail does not at all depend on age, but varies in different persons according to the formation of the eyes, the treatment they have received, and the constitutional capability; therefore, the age of the person requiring spectacles gives but a vague general idea to the optician as to what is required, unless other particulars are stated; such as whether glasses have been used before; the distance at which writing and printing is seen pleasantly without assistance, the focus of those last used, or sending even but a broken piece of the same.

"The proper selection of spectacles for imperfect vision is a point of much deeper importance than is generally believed. An _oculist_ who is only acquainted with the diseases of the human eye, without possessing any knowledge of it as an optical instrument, is often led professionally to recommend glasses when they ought not to be used, or to fix on focal lengths entirely unfit for the purpose to which they are applied, and the _mere vender_ of spectacles and lenses is still more frequently in the habit of proffering such counsel."—BREWSTER.

The near-sighted, or those who require concave spectacles should use those of the slightest power; No. 0, or No. 1, will generally be sufficient at first, but this, by the aid of the trial box, can readily be determined by the wearer himself. There is such an immense benefit experienced by the short-sighted from spectacles which suit their sight, that to argue for their adoption of them would be quite superfluous. Without spectacles they are excluded from observing beautiful landscapes, recognizing individuals, or viewing to advantage any of the crowd of interesting objects around them; but by adopting them they are placed on a par with the long-sighted in such circumstances, while the sharp and microscopic character of their sight _without_ spectacles, gives them many advantages over those possessing ordinary vision.

The short, or near-sighted eyes, have the cornea, and often the crystalline lens, more convex or arched out than in long-sighted eyes. This formation causes the rays to converge to a focus before they reach the retina, but by the application of a concave lens the difficulty is corrected, and the rays are carried on to their proper point for giving a perfect representation on the retina.

This character of sight is very frequent, and is more particularly remarkable among those whose mode of life restricts them to crowded cities, sedentary employments, and confined situations. Those whose infantine and youthful years have been passed in the country, or where the eyes have had a free range of view, not circumscribed by the walls of the nursery, or limited to the observation of objects near at hand, rarely require concave spectacles.[4]

The spectacle-frames next demand our attention, as our utmost care in judiciously selecting lenses of the proper focus for our sight will be neutralized if the frame or mounting in which they are placed does not apply comfortably to the head, leaving the lenses they carry fair and parallel before the eyes. If the front of a pair of spectacles is too short for the wearer's face, he will look upon the edge of the lens, and a portion of the exterior rim of the frame; if they are too long his eye will meet the opposite edge and inner curve of the rim.

Spectacle-frames are fashioned to suit the variety of formation in different individuals, and therefore such should be applied as adapt themselves pleasantly to the temples, across the forehead and before the eyes. The pupil of the eye should, when looking at an object directly before it, see through the centre of the spectacle-eye, so that if the whole of the glass, except the small centre, were painted black, the rays of light would pass through it without distortion of the pupil. The bridge or nose-part of the spectacle-frame should be arched out, made like the crank of a lathe, or perfectly parallel with the knuckles of the sides, according to the formation of the wearer's nose, otherwise the spectacles sit awkwardly on the face too far from or too near to the eye-lashes, with their centres too high or too low for the natural exercise of sight. Trifling as these particulars may seem, they cannot be neglected with impunity. Where these defects are unattended to, the eye is tortured by straining to overcome the difficulty, and striving to accommodate itself to them, instead of their being shaped to meet its requirements. Some old-fashioned spectacles have

short side-pieces, which press most unpleasantly on one point of the temples, and when closed scratch and rub the lenses. Others have very cumbrous and heavy sides, with double lift or common hinge-joints. These also scratch the lenses when folded up, and can only be worn with any degree of comfort when the head is uncovered. Decidedly the best constructed spectacle-frames are those which, without being clumsy, have enough strength to admit of the sides being extended the full width of the face without bending the front, with single sides rather longer than their front for ladies' use, and with turnpin sides (an extending joint, turning on a pivot,) for gentlemen.

The material of which they are composed should be either gold, silver, or enamelled blue steel. Tortoiseshell, also, when well made, is very light and pleasant to wear, particularly for ladies. There is no advantage in large size, or round-eye spectacles, to compensate for their clumsy appearance and great weight; we get a sufficient expanse of observation with the oval-shape glasses without harassing the eye with an excess of light, which the large glasses admit.

Solid blue steel mountings are a decided improvement, and are invaluable for persons who constantly require spectacles. They are wrought from a plate of steel, and shaped as light and uniform as any other town-made elastic blue-steel spectacles, with the advantage of being more durable, and eventually less expensive; for as they have no soldering in their composition, it is scarcely possible to break them, and therefore they rarely want repairing. Blue steel spectacles, in consequence of their being so much in request, are coarsely imitated, and vast numbers are sold by the pretended cheap shops, at apparently low prices which the wearer will find to be immensely beyond their real value. There are thirteen different qualities of the spectacles termed blue steel. The chief part are country made, and roughly put together, some being all iron, others having iron fronts and steel sides; others again bear a tolerably close resemblance to the best town-made articles, and unless the two are compared together, are likely to deceive a casual observer.[5]

The fine elastic blue steel, of the best quality, are exceedingly light, highly polished, and beautifully enamelled. They will retain their appearance for two or three years, when carefully used; and they can be restored to their original appearance at any time for a few shillings' expense.

The anti-pressure spectacles are made of gold, silver, or the elastic steel. They are not adapted for ladies' use, but for gentlemen have been much in demand, as they obviate the necessity of opening and closing a second joint or lengthening piece, and do not press or annoy the nose or temples, but by an equal tenacity preserve their proper position before the eyes.

Single eye-glasses, though very convenient for occasional use, are not to be compared with spectacles for the agreeable and natural assistance they give to vision. The eye should not be dependent on them for continuous assistance. Those who persist in using them should do so as little as possible; but the wiser course is to discard them entirely, and adopt the double eye-glasses where it would be tedious to apply spectacles of the usual kind.

That the vision is more natural and perfect when both eyes are employed than when one glass only is used, must be self-evident, as the axis of each glass, placed as they should be in the spectacles, coincides with the axis of each eye, and the rays of light are thus equally refracted to the eye. Again, the eyes have a most acute and sensitive sympathy with each other, and when a single eye-glass is constantly used they are unnaturally exercised, and prevented from acting in concert. One eye (generally the right eye) has the glass perpetually applied to it; and very frequently, in consequence of this pernicious practice, becomes of a different focus to the other. Mr. George Adams informs us that he did not recollect an instance of a short-sighted person who had occasion to increase the focus of his concaves if he began by wearing spectacles, but that the cases were frequent, where a single eye-glass had been used, in which the persons had frequently required a change of glasses.

The prices of spectacles are diversified and fluctuating, like all other manufactures, so that to publish a list of prices would only tend to mislead and deceive my readers. For instance, the price of a pair of pebbles, used formerly to be one guinea extra to the charge for glasses; they are now reduced to half that sum. A pair of pebbles, of the concave or of the periscopic figure, were at the same time charged twenty-five shillings. These have been reduced in the same proportion. And it cannot be too universally known, that a person can have a pair of good convex glasses fitted into his spectacles, and correctly suited to his sight, at from one shilling and sixpence to two shillings per pair, by any respectable optician. The poorest person may be defended against the tender mercies of the spectacle speculators; for he really can obtain a better article for his money, both in quality and suitableness to his sight, of the respectable optician, and, upon an average, at _a less cost_ than the cheat contrives, by dint of manœuvring, to extract from him. Good lenses, in plain frames, or, in other words, a good pair of spectacles, may be had, correctly suited to the sight, for two shillings and sixpence. Who then, knowing this, would suffer his sight to be tampered with? Truly, those who would stickle for a

shilling in the price of such valuable and essential instruments

“Deserve not the comfort they shed o’er the soul.”

Yet, at the same time, there is no reason why those exorbitant charges should be submitted to, which are often paid without hesitation by the delighted purchaser, when a pair of spectacles appears to suit his sight.

The love of the marvellous, and the insane thirst for novelties, are strikingly displayed in many inquirers for spectacles. The honest, straight-forward, and disinterested counsel of the established tradesman, is looked upon with scowling suspicion; but the preposterous and shallow pretensions of the empiric, decked with all the paraphernalia of fudge and falsehood, are listened to with eager curiosity. If the writer looked to self-interest as his guiding star, his course would be to preserve silence on these subjects; since it needs not to be demonstrated, that the practice and the profit of the regular practitioner are increased by the patched-up and mangled cases, which are, as it were, provided for him, over and above the number who _legitimately require_ the exercise of his skill. But he despises such mercenary calculations, and contends that “The happiness of mankind at large is a principle that ought to be followed out by all individuals at every personal cost, and against every kind of opposition.”—_Medical Examiner._

FOOTNOTES:

[4] In Russia the person having short sight is seated in a chair for several hours daily, with the head placed in a natural position for reading, but prevented from pressing forward. The page is at first placed at the short distance at which the eyes have been accustomed to observe; but this distance is gradually extended, until the humours of the eyes, constantly exercised in endeavouring to accommodate their powers to the gently increased demand upon them, at length acquire the capability of observing at the usual distance.

It is undoubtedly the fact that this character of sight may be acquired; many instances could be adduced of watchmakers and others, whose employments are of a sedentary or studious character, becoming short-sighted.

[5] It will be perceived that it is the workmanship and nice finish of the best town-made spectacle-frames which necessarily increases the price. Thus, a single pound of pig iron, which costs one penny, can be manufactured into watch-springs of the value of £240.

CHAPTER IV.

“Allured by hope of plunder, and intent By force to rob, by fraud to circumvent,”—ÆNEIS.

I shall give a few instances of the manner in which advertising adventurers rack their ingenuity to dress up their announcements in the most catching and attractive style; and, failing to find language sufficiently striking and pointed to arrest attention, scruple not to manufacture terms and apply similies, which, however preposterous and absurd they are seen to be when examined, yet answer their purpose of mystifying the public, and inducing a purchase of the vaunted articles.

We have only to glance at the columns of our newspapers, and the covers of periodical publications, for illustrations of the extent to which the system of scheming, falsehood, and trickery, termed puffing, is carried. In one specious and lofty-toned announcement we are told that the most splendid discovery of the present age is now admitted, by the most unquestionable (?) testimonials, to be “Grindstone Snuff,” which is warranted to cure gutta serena, cataract, and all other diseases of the eyes, while a single pinch scares away headache and nervousness! Another startles the weatherwise by his impudent pretension to be the _only_ maker of barometers and thermometers in London; whereas, if the real truth were disclosed, it would be found that his connexion with the trade consisted in some such occupation as engraving the index plates of the instrument for his employers, who surely have the greater right to be considered real makers. Balsams, cough drops, rheumatism and gout dispersers, pills, cerates, syrups, shaving soaps, cornplasters, and heal-alls—all boast of the wondrous cures effected, and testimonials received. The long list of essences and decoctions, from vinegar to honey, also have the names of distinguished gentlemen of the faculty, the royal family, nobility, clergy, and gentry, appended as bearing testimony to their surprising virtues. “Highgate’s universal irresistible Ointment” we are informed, is an invaluable specific for all disorders.

“But who shall decide when doctors disagree?”

A counter address denounces the same individual as an _uncertificated impostor_, who has no testimonials of his own, but has filched extracts from the only real original certificates and testimonials of “Monsieur Holabolo’s genuine Panacea,” which alone is a radical cure for all internal and external complaints. Another ointment puffer, whose nostrum is warranted to cure the plague and cholera, among other evils, occupies two columns of a newspaper with cures said to be effected by it; and these are flanked with no less than seventy-six names of surgeons and oculists, who, among others, testify to its monstrous virtues!![6]

Now in all these quack advertisements, we find the names, titles, and residences of the professional gentlemen correctly given, which, possibly may be of some consideration. Indeed, I know it is to some few an advantage not to be overlooked, as their names are thus kept before the public eye free of expense to them, and they are, although indirectly, as effectually puffed into notice as the quack himself. Without charging the respectable and high-minded members of the profession with entering into a compact, and designedly lending the sanction of their name and office to these abominable schemes of imposition, and granting full force to the apologies they offer as to its “being customary;” “that the profession generally do it;” “that to interfere would be expensive and troublesome;” and that “it is the fault of the public, who suffer themselves to be deluded by such shallow artifices,” I conceive it to be the bounden duty of every man of honour, when those tricksters employ his name without his sanction or authority, to adopt measures to disabuse that very large section of society, who attach full credit to statements appearing under such auspices.

But it is with spectacle advertisers that we are more immediately concerned, and it is therefore essential to convince every individual of ordinary capacity, that he can, by the exercise of common sense, and the moderate use of his reasoning faculties, safely and judiciously determine for himself, when spectacles are required, and what powers and qualities they should possess; either when the eyes first require restorative aid, or at any subsequent period of life.

Amber spectacles have been bepraised and forced into notice as much as any of these quack specifics. I consider that the apathy and indifference manifested by those who know the statements put forth to be a tissue of falsehoods, are extremely reprehensible. No wonder that thousands have been tricked and trifled with when such novel and plausible pretensions have remained unchallenged, and those who know them to be hollow and deceitful artifices have suffered them to remain unexposed. Amber is so soft that a proper degree of polish cannot be given to it to make it suitable for spectacles. The streaks, specks, veins, and irregularities in it may be detected by the most casual observer. Glass and pebbles assimilate closely to the composition of the eye itself, but amber only imitates its diseased and decayed appearance. When the powers of the eye begin to decline, the crystalline humour becomes somewhat yellow, and as the decay proceeds this tinge increases.[7] Amber is strongly charged with electricity; it has an affinity for oil, grease, and human perspiration; “and it was from amber that the electrical fluid was first obtained.”[8]

Since writing the above, I have received, by the medium of the twopenny post, a printed circular, headed, “_Amber Spectacles._—M——having experienced from the use of amber spectacles that which is expressed by the following eminent gentlemen, considers it to be his duty to caution the public against the use of them:— “Amber is a soft substance, and it is impossible to form it into a perfect lens, and a lens improperly constructed would prove most injurious to vision. Amber, in a moderate heat, becomes sticky; and by cleaning it in a short time, the polish wears off. It is also easily scratched, and soon loses the little transparency it possesses. Glue, as to substance and colour, is quite equal to it; and although purchasers pay an enormous price for amber spectacles, yet they incur a great risk of materially injuring their vision.”[9]

If there even were any merit or superiority in amber spectacles, be it observed, that the persons who prate about _their_ discovery, are not the parties who originated or introduced the article. I have in my possession several which were first brought to this country, and sold by a Prussian mechanic, long before he came in contact with individuals, who took a shameful advantage of his forlorn situation, and, after deluding him with specious promises, reduced him to their own terms. The poor man found remonstrances to be unavailing; and as he knew that redress was both uncertain and expensive, he refrained from farther interference, sighing as he said,—

“My poverty and not my will consents.”

Cautions respecting amber spectacles have frequently appeared in the daily newspapers. On the 17th of APRIL, 1838, the “_Sun_” contained a long advertisement, lauding their extraordinary virtues. In the same page, followed an exposé of the puff; and in another part of the paper was the following paragraph, made to appear as the editor’s remarks:—

“An advertisement appeared in our paper of the 9th instant, calling into question the merits of patent amber spectacles, which have been so highly recommended for the preservative and assisting qualities for defective vision, by men of high character and professional reputation. The names of Messrs. Dollond and Curtis being used, it is right that the public should be apprised of the

ascertained fact, that it owes its insertion, not to the knowledge of those gentlemen, but to the personal pique of interested individuals."

Persons who are somewhat acquainted with the manner in which such paragraphs are got up, well know what importance is to be attached to them; the uninitiated, however, are led to suppose that Messrs. Dollond and Curtis were not of the opinions expressed, but that some of the trade, jealous of the advertisers' "high character," had maliciously questioned the "superior refractive property," "light modifying," "cool," and "soothing" attributes of the admirable amber. But what ought we to think of the professional and literary characters who countenance the system of fraud and delusion practised by puffing advertisers. We might in charity suppose that the signatures of those eminent persons were surreptitiously obtained; and in that case, the straight-forward course they ought to adopt, should be publicly to disavow all connection with the cheats. But if they really hold the opinions attributed to them, we are bound to declare that, opposed as such idle notions are to truth and common sense, their presumption is ridiculous in publishing opinions on a subject of which they are grossly ignorant—ay, grossly ignorant! however capable and popular they may be in their own professions. Indeed many names of able and skilful surgeons are enumerated in the list of patrons and testimonial writers, who would smile at the effrontery of self-dubbed opticians, and the credulity of the public, conscious that they had no pretensions to any superior acquaintance with the subject. The ingenious and talented Dr. Neill Arnott remarks, in his "Elements of Physics,"—"Will it be believed that _there are medical men_ who neither understand mechanics nor hydraulics, nor pneumatics, nor optics, nor acoustics, beyond the merest routine; and that systems of medical education are put forth at this day, which do not even mention the department of physics or natural philosophy;"

But a general diffusion of knowledge is changing the condition of society, and elevating the human character. At first we almost tremble at our own boldness, in demanding proofs of the capability of our teachers; but the mind, gathering power, and unfolding its strength, with every opportunity for its manifestation, insists on having positive proofs, rather than vague pretensions, and demands solid information, instead of empty nothingness, however gorgeously arrayed, or pompously introduced.

FOOTNOTES:

[6] As for operators on the teeth, they have multiplied exceedingly in the land. Their successful career is a _biting_ satire on the credulity of their supporters.

American Quackery.—The cost for advertising quack medicines in the United States, annually, is estimated at 200,000 dollars. A peck of pills per day is considered necessary for Boston, and half a bushel for New York. On an average, only one in twenty-five who take them is actually sick; and the proportion of those dispensing with some necessary of life to purchase nostrums, which do them a positive injury, is in the ratio of eighty-seven to every one hundred throughout the country.

[7] Dr. Petit found the crystalline in the eye of a man eighty years of age so yellow as to resemble amber.

"When exposed to heat it becomes soft, swells, bubbles up, is apt to take fire, and burns with a yellowish flame."—_Heron's Chemistry._

"It gives out electricity by friction. It is an indurated vegetable juice, and not produced by the laws of crystallization, but by the same causes which influence the mechanical condition of gum arabic, and other resinous substances. Insects are often found embedded in it."—_Parkes's Chemistry._

It is a fact, that to silence such objections, a great improvement in amber, very pure and costly, was announced; this was nothing more nor less than yellow plate-glass, the same as is used in stained-glass windows. I have several specimens of these "superlative patent amber" in my possession.

[8] Dr. Neill Arnott.

[9] Dollond—Curtis.

CHAPTER V.

"Nothing extenuate or set down aught in malice."—SHAKSPEARE.

Some instances which have come under my own cognizance will illustrate the way in which gross imposition is practised, and the public morals materially injured, by weakening confidence in those who are, from their education and rank, looked to as guides and

preceptors, and causing the mind to turn with indignation from the needy, but debased and grovelling creatures, who resort to any means, however infamous, to effect their selfish purposes.

A military gentleman, of Stonehouse, was waited upon by a renowned optical quack, who, the moment he entered the parlour, exclaimed, “Goot Got, Sar! vy, you are a’goin plind; the sight is leaving your left eye! If you don’t immejartly take to my improved classes I vill not answer for the konserkences; kataract will grow on it in a month!” The gentleman, taken by surprise, tried on some of the _preservers_, and finally purchased two pairs of hand-folding spectacles, for which he paid four pounds. Some time after, they were more particularly inspected, and proved to be common glass, instead of pebbles, as was represented, and of much stronger focus than the eyes required. The full London retail charge for _such_ articles is 10_s._ per pair.

In the same town the same _distinguished_ individual forced his way into the study of a reverend gentleman, and alarmed him by a similar prognostication. A pair of the “clarified crystals, ground by a peculiar process,” were purchased, price fifteen shillings. Afterwards, upon finding that one eye was irritated, and derived no assistance from the spectacles, the gentleman called upon the optician who had always previously supplied him, and was convinced of the trick which had been put upon him. They were common machine-worked glasses, each of a different focus, and neither of them suitable to his sight. Their proper price, sold in their proper place (viz., by hawkers, in the streets,) is one shilling per pair!

A gentleman of Norwich, struck with the advantages promised by some extraordinary spectacles, paid two guineas for a pair of blue steel, with blue glasses, which were warranted pebbles,[10] and had the additional vexation to be severely censured by several friends, who complained that the fellow had fixed them with similar trash by representing that he (the gentleman) had said, “After you leave mine, do you go down past the Norfolk Hotel, and say I bid you to call on Mr. and Mrs. ——, to sell them spectacles such as I have bought.” This, of course, was a manœuvre of the cheat himself.

A gentleman, of Tavistock, purchased a pair of silver spectacles, declared to be very fine pebbles, price thirty-five shillings; they were merely glass; and as he required a glass in an old pair of spectacles, the pompous hawker offered to _oblige_ him by putting one of his “clarified lenses” to match the focus: for this he charged five shillings and sixpence. It was two inches different in focal length to the original glass! which would have been properly matched, by any resident optician, for one shilling!

One of the hawking tribe called at the residence of Major C——, near Hereford, and represented that M——, Esq., had ordered, on the previous day, two pairs of spectacles, and desired him to call upon his friend, the major, to suit him also. In this case the attack was parried; and, spite of the hawker’s vehement declaration, that the eyes were in a terrible state, he was dismissed, “to call again to-morrow.” Thus the major preserved his eyes, and saved his money. In the evening he saw his friend, and inquired if he had sent a fellow to his house with spectacles? “No,” was the reply, “but you sent him to _me_; for he came this afternoon, saying you had bought two pairs, and wished me to have some of the same kind; therefore, I bought two pairs, and paid him the price he said _you_ gave, viz., three pounds, ten shillings, though at first he wanted four guineas!”

A naval captain, residing at Monmouth, showed me a pair of silver spectacles with six-inch focus glasses, very jagged and splintered at the edges, worth at most twelve shillings, for which he had given one of the tribe of impostors two guineas, and a pair of tortoiseshell (which _did_ suit his sight) into the bargain.[11]

A lady at Belfast was attracted by the showy advertisement of an itinerant optician, and called upon him, “between the hours of ten and six,” for the purpose of purchasing a pair of spectacles. The first thing he did, after staring at her, and impudently declaring that her eyes were being ruined, was to snatch her spectacles from her face, and put a pair of his own in their place. “There, Matam! they are the spattacles for your eyes, those you have peen vearing vill pring on kataract.” “I see pretty well in these,” said the lady, “but my own suit about as well, I think.” “Oh dear no, it’s quite a mistake, your own are retched; put them on—isn’t there a differench now, Matam?” “Yes, there is,” said the lady, (who had too much penetration for the pedlar) “they require cleaning after having been held in your hot hand all this time;” and taking up a washleather she wiped the glasses, and, replacing them, bade adieu to the _testimonialed_ optician.

A lady, who was visiting for a few weeks at Margate, was startled one morning, by a big, blustering, shewily-dressed man, who, after knocking at the street door, pushed past the servant, and rapping loudly at the parlour door opened it without waiting for any reply. “Goot morning, Matam, I am the optician to the royal family; your friend, Lady W——, terives so much goot from my pellucit lenses, she peggd me to call and suit you.” Before all this had been uttered he had taken a package from a confederate, dressed as a livery servant, who accompanied him, and covered the table with his stock. “Your eyes are in a most alarming state Matam, this pair of cold spattacles will suit you.” “Really,” said the lady; “how came Lady W—— to suppose I wanted spectacles? I have never

worn any at any time in my life." "No, that's the vary reason your sight is leaving you; your eyes are vary pad." "What is the price of this pair?" inquired the lady. "Three guineas" was the answer. The price was paid; and after punishing her eyes for a few days, the lady met with a scientific friend who convinced her that they were totally unfit and improper for her, her eyes being in excellent order, and not requiring spectacles at all!

A gentleman, visiting at Canterbury, in 1834, was induced through the representations of the same notorious cheat to purchase a pair of spectacles, which were warranted to dissipate the cataract forming in his eye; the price paid was five pounds. As he was lamenting the terrible state in which he was informed his eyes certainly were (although, strange to say, he was quite unconscious of it) another pair was placed upon his nose, which, he was told he ought to wear as a change, in case the eyes were pained by the efforts of the first pair to dissipate the cataract. Another five pound note was handed over to the hawker, who began to grow quite pathetic; and artfully alluding to the services of the gentleman during the war, and expatiating upon a few circumstances with which he had made himself acquainted in a chat with one of the gossips at the public house where he lodged, he pretended to lament the necessity for the gentleman staying within doors. "What, may I not take a walk or ride as usual? I can't endure being cooped up within doors." "There's danger in your going out," said the pedlar, "except your eyes are guarded with green Refractive Preservers." "Oh, bless me," said the gentleman, "that's very serious; then you really think I ought to have another pair for walking and riding, eh?" "Oh certainly, by all means; nothing else can save your eyes, unless you confine yourself within doors." "What's the price of such a pair of preservers?" "Six guineas, Sir; but as you have bought the others you shall have them for five pounds." "Why, dear me, I shall be ruined in buying spectacles, and yet I never felt that I wanted them before." "That's just the vay, ven the eyes are a'going blind it comes on all at once, my tear Sir."

By this transaction the pedlar actually pocketed three five pound notes. In less than a week afterwards the first two pair were sent to me to have the yellow coloured glasses exchanged for white lenses of four degrees less magnifying power; the price at which the whole three pairs could have been purchased elsewhere would be forty-five shillings.

It will scarcely be credited that the individuals who thus practise on the public are grossly ignorant; and were it not that the anxiety of the purchasers to possess something extraordinary renders them liable to imposition and allays suspicion, such shallow pretensions never would pass undetected.

One of the tribe, who, until lately, practised the art and mystery of his forefathers as a dealer in old clothes, suddenly changed his _profession_, and, calculating the chances to be two to one in his favour, ventured, neck or nothing, to blazon himself forth as an experienced, scientific, and practical optician. A book, bearing his name as its author, and sundry special appointments, obtained by dint of the most brazen assurance and persevering importunity, were ostentatiously paraded before the wondering eyes of her majesty's liege subjects. The public are stultified, and the eminent individual himself, is almost astonished that the scheme should take, and like the "Fly preserved in amber, wonders how the d—— he came there."

There are artists in his locality who can give many _graphic_ illustrations of the disregard to truth, violation of friendship, and cunning perversion of facts, of which this individual has been guilty, and yet no one has a greater array of eminent names and testimonials to show—many signatures of really clever men having been obtained by some means or other. Surely there is much piquancy and truth in the Spanish proverb: "those who know most are oftenest cheated."

FOOTNOTES:

[10] Pebbles, it is scarcely necessary to say, are colourless.

[11] This gentleman stormed most lustily when made aware of the trick which had been practised upon him, and threatened legal exposure to the "professional optician." But this course is seldom resorted to, the dupes recollecting that, while they publish the swindler's villainy, they give us but an indifferent idea of their own discernment, beside the uncertainty and incongruity ever attendant upon Law, thus quaintly sketched by Bentham;—"If a man give you a black eye, you make him pay for it, but if he put your eye out, you get nothing; and whatever is taken from him goes nominally to the queen—really to John Stokes or Jack Nokes who have no concern at all in the matter. If a man kill your pig, you get the value of it, but if he kill your wife or your child, you get nothing—if any thing is got out of him it goes to a stranger, as before. A man sets your house on fire, if by misfortune, you receive amends, if through malice, you receive nothing."

CHAPTER VI.

“See, arm’d with great authority, they come, And with great names and numbers strike us dumb; Reason and common sense to names must fall, And strength of argument’s no strength at all.”—DODSLEY.

I will now produce a few specimens of Puffing Advertisements, which will show how sounding words are senselessly strung together to give an air of importance to their originators, and leave my readers to judge for themselves how far the public ought to be influenced by them. The orthography (?) of these puffs is, in every way worthy of the authors of them. They are given _pure_.

PUFF, No. 1.

Improved Eye Preservers, patronized by the Faculty of the Eye Infirmaries for Cataract, and other improved glasses.

Mr. —— optician to the Queen,[12] Her Royal Highness the Duchess of Kent, &c. sole Inventor of Optical Glasses, ground and shaded on the Exact[13] Principle. Mr. —— has been for twenty-five years a manufacturer, who has devoted his study with time to bring this branch to perfection. Mr. —— has been earnestly solicited to pay a short visit for a limited period. He has the honour to announce his arrival from the London, Bristol, and Edinburgh Optical Establishments.

Spectacles for far and near distances, for those who have a full eye, ground in a peculiar manner.

Sight is often abused by inexperienced persons taking upon themselves the impracticable task of assisting it.

The Improved Spectacles, and other glasses, made by Mr. —— on the authority of professional gentlemen, are the very best ever invented; they have gone through a different process, which clarifies and makes them the greatest improvement ever heard of by candle light or dull day.

Mr. —— can tell by the physiology and figure of the eye when to give the greatest assistance. His glasses are of a refractive quality; so constructed as to effect the greatest relief; manufactured by machinery of a new construction, and by a peculiar way. Turbid glasses destroy the cornea and iris of the eye, and harbingers all ocular diseases.

*** A book will be given for the use of the Improved Spectacles and advice for all diseases.

Sight is injured by buying Spectacles of Shops, or other _chance_ places of sale, totally unacquainted with vision.

Ladies and Gentlemen whose eyes are weak will, by using these extraordinary Spectacles for two or three hours a week, find their matchless qualities, as they are ground in a peculiar way.

Mr. —— will call with a large Assortment.

LICENSED HAWKER, NO. ——

*** This Circular will be called for.

PUFF, No. 2.

The sight of the aged assisted by the Improved Spectacles, upon unerring principles.

Persons have been going round copying Mr. ——’s Bill, who is the only real original manufacturer of them?[14] it has been the cause of many persons nearly losing their sight, Mr. —— has had fifteen years practice on the eye: there is such a monstrous difference in these improved glasses, that one pair will serve a person his whole life. The sight of the aged assisted, the weak strengthened, and the perfect improved, by Mr. ——’s improved spectacles.

Spectacles for those who have a full eye; the glasses are ground in a peculiar manner. Blindness has took place from the ignorance of persons wearing the glasses in common use, owing to the glasses _drawing_ the eyes. These glasses are highly recommended by professional gentlemen, who view them to be the greatest improvement ever known; they have gone through a different process, which clarifies them, and makes them the greatest improvement by candle light or dull day, qualifying you to see the greatest length of time at one sitting; those persons whose eyes are weak, by using a pair of those extraordinary preservers for two or three hours will find they are ground in a peculiar manner.

A treatise will be given for the use of the Improved glasses, with advice gratis for all diseases of the eye. Mr. —— flatters himself he can perform the most difficult cures in the sight with the greatest ease; there is no complaint of the eye but he is acquainted with.

Mr. —— cautions the public against a person who is selling Spectacles which pretend to be his.

Mr. —— will call with a large Assortment of Improved glasses, which will give satisfaction.

LICENSED HAWKER.

PUFF, No. 3.

Caution against a person taking the name of Messrs. ——, the professional opticians: and imposing upon ladies and gentlemen in selling shameful spectacles, as Messrs. —— improved, and charging forty shillings, while Messrs. —— only charges for the same twenty shillings, or, with pebbles, only fifteen shillings.

PERMANENT RELIEF

for all disorders effecting the eyes, and cases of dimness. Were it necessary,

A HOST OF CASES

might be named by which persons, distinguished, have, by their improved scientific and successful using of their

IMPROVED GLASSES

been much benefitted. The honourable patronage noticed at the head of this article, and their hourly increasing patronage, are proofs of their great skill and talent for

ALL DISORDERS OF THE SIGHT.

They have the honour to be professionally consulted by the chief families in the empire. Imperfect sight can only be handled properly by those who by deep study have a talent for

THE ORGANS OF SIGHT.

Many people injure their sight by buying improper spectacles, whereas it is

THE ESPECIAL OBJECT

of Messrs. —— to rest the claim of patronage on those numerous persons of the first quality.

THE NOBILITY AND GENTRY

May be suited with Spherical Pellucid Glasses, of every class, according to their exalted rank.

THE MERCANTILE AND LABOURING CLASSES

may have their daily toil sweetened by these improved glasses; administered, in cases of distress, on terms accommodating to their situations in society.

LICENSED HAWKER, No. ——, A.

PUFF, No. 4.

For a short time only.

Mr. ——, Optician to their Royal Highnesses the Prince and Princess of ——, King and Queen of ——, has the honour to inform the nobility and visitors of ——, he has arrived from the London Royal Eye Infirmary, for a short time only. A reference to the distinguished patronage he boasts, will convince the public he possesses great skill in the Optic Line, and is without a parallel when such organs as the eyes is liable to evils from common glass and pebbles, one being no better than the other! It is his imperative wish to guard the public against them; therefore, he announces his stay will be for a short period.

LICENSED HAWKER, No. ——, B.

PUFF, No. 5.

MAY BE CONSULTED,

Mynheer ——, Practical and Professional Optician, Surgeon-Oculist and Surgeon-Dentist, announces his arrival. In all recent or chronic weakness, a perfect cure is his far-famed Keysell Spectacles, which have the density and translucency of a diamond, and refractive preserving powers, being composed from rare crystals, produced from the Carpathian Rocks, so highly recommended by the faculty. Mynheer M —— being based upon the greatest perfection which the dento-chirurgical art can be carried, can renovate all decay by his succedaneum, which all the faculty of the continental cities recommend. In two seconds it removes pain, and lasts many years.

But it is to the Keysell Spectacles and Terrence Teeth that he would _draw the eyes_ of his friends to: they are fixed in the mouth so that it is impossible to remove them without wires. They increase the beauty by their elegant matchlessness.

LICENSED HAWKER, No. ——

PUFF, No. 6.

POSITIVELY FOR THIS WEEK ONLY.

Messrs. —— have succeeded, after fifteen years' professional practice, and devoting their whole lives to the optic line, in bringing out a wonderful translucency for the organs of sight, coupled with a conductor for deafness. This wonderful discovery brings faulty hearing to perfection. They are so arranged and combined with scientific principles, with the long practice of the inventors, that they will allow such an extent of relief that will quite astonish every beholder.

They are anxious not to be confounded. There are other people who pretend to the skill of Messrs. ——, therefore the public are liable to be imposed upon. Inferior spectacles can be had of persons calling themselves opticians, but Messrs. —— think it is scarcely necessary to state, that their improved Translucency for Spectacles, and Conductors for Deafness, are manufactured under their own eyes, upon spherical principles.

LICENSED HAWKERS, No. ——

One of the Firm may be professionally consulted from 10 to 6.

PUFF, No. 7.

IMPORTANT DISCOVERY.

Mr. ——, Professional Optician, patronized by the faculty of London, Brighton, Bath, Edinburgh, Glasgow, and Paris.

Spectacles ground and shaded on the exact principle of truth, by Mr. ——, the celebrated Optician from the London Optical Establishment, established for a number of years.

Mr. ——, in consequence of the flattering encouragement he received from the first families, he has established himself here for a short time. He has made the study of vision his own, and can remedy any organic defect, neglect, disease, or imperfection. Many individuals of rank and royalty acknowledge the immense improvement. Mr. —— will send a treatise, explaining every thing in the line, to every house, and will attend himself with a splendid quantity of improved glasses.

As several persons travel through the country in his name, he begs the public to look at his patronage at the top of his circular. He is the sole Inventor of the Improved glasses. They have gone through an elaborate process, they are therefore clarified and pellucid. They throw a clearer light, and more brilliant than any others.

*** At home from 2 till 6.

LICENSED HAWKER, No. ——

Please to observe the brass plate in the window.

How often, too, accompanying such advertisements as the preceding, do we find paragraphs, in the laudatory style, to some such effect as the following (see also page 44). It requires but little penetration to arrive at a conclusion as to who are the authors of them.

PUFF PARAGRAPH, No. 1.—We again call the attention of our readers to Mr. —— and his valuable assortment of Spectacles. They are manufactured with extraordinary care, and constructed upon the strictest scientific principles. M. —— has for a long period past devoted his attention exclusively to that important branch of optics—the human eye;—and the proficiency he has attained of the complicated structure of that noble organ has enabled him to adapt glasses to every degree of defective vision. But the highest panegyric which can be pronounced upon the skill of this artist, is the unprecedented number of applications which have been made to him.

Our readers will observe, that his stay is restricted to a few days.

* * * * *

PUFF PARAGRAPH, No. 2.—We have more than once had occasion to allude to the surreptitious conduct of individuals, who are eager to profit by the established reputation of our resident opticians, Messrs. ——, who are about making arrangements for visiting all the neighbouring towns, making this place their permanent residence.[15]

The “Messrs. ——,” the “resident,” the “distinguished,” decamped at the expiration of three weeks.

FOOTNOTES:

[12] The royal arms appear at the head of this elegant announcement. (Query) Ought not the proper authorities to prohibit such vile use being made of the name of royalty.

[13] Query—_Exaction_ principle.

[14] Were those individuals really _manufacturers_, they would not require a Licence to vend their articles. See Act of Parliament, 50 Geo. III. cap. 41, sec. 23. enacts: “Provided always, and it is hereby enacted, that nothing in this Act shall extend to prohibit any person or persons from selling any printed papers, licensed by authority, or any fish, fruit, or victuals; nor to hinder the _real worker or workers, or maker or makers_ of any goods, wares, or manufactures of Great Britain, or his, her, or their children, apprentices, or known agents or servants usually residing with such real workers or makers only, from carrying abroad or exposing to sale, and selling by retail or otherwise, any of the said goods, wares, or manufactures of his, her, or their own making in any mart, market, or fair, and in every city, borough, town corporate, and market town. Nor any tinkers, coopers, glaziers, plumbers, harness makers, or other persons usually trading in mending kettles, tubs, household goods, or harness whatsoever, from going about and carrying with him, or them, proper materials for mending the same.”

[15] It is gratifying, however, to find that many editors of newspapers repudiate the iniquitous system, perceiving that their readers might justly look upon them as participators in the fraud.

One of the puffing, _professional_ licensed hawkers entered the office of the Reading newspaper, and with the authoritative air of an Alexander, desired that his announcement should appear in the front column, and the _usual_ laudatory paragraph in another part of the paper. He was informed that his advertisement could be inserted, but that the proprietors had determined never to admit such insidious clap-trap notices, which, while they injured the resident tradesman, and were looked upon as the _bona fide_ opinions of the editor, generally referred to matters of which he could not honestly express a favourable opinion. The pedlar stood aghast! “What,” said he, “not put in a paragraph? Why, I’d sooner pay for a good paragraph than care about the advertisement at all.”

His _professional_ visit was of unusually short duration, finding it impossible to bribe the press to trumpet forth his praise.

CHAPTER VII.

“It is a strange thing to behold what gross errors and extreme absurdities men do commit for want of a friend to tell them of the same! The help of good counsel is that which setteth business straight.”—BACON.

I have, for many years, visited nearly every town in the kingdom, on commercial pursuits, at intervals of six months; and wherever I have met with the brazen advertisers alluded to, I have issued public notices, and inserted counter-advertisements, to put my friends and the public on their guard against such egregious imposition. Such a step, spiritedly carried out, has uniformly proved successful, and the notable pretenders have decamped from Bath to Norwich, from Brighton to Carlisle, sometimes assuming other names, or changing the initial letters; as S. and E., who had been vapouring away at Norwich, suddenly flitted to Margate, and

there announced themselves as C. and B., the celebrated opticians from the Royal Eye Infirmaries, &c. &c. For low cunning and unprincipled trickery, such adventurers as I have described, stand unrivalled. Upon several occasions they have echoed my cautions, and copied, word for word, remarks levelled at themselves; hoping thus to shield themselves from detection, and confuse the public in identifying them; as the pick-pocket, when the hue and cry is raised of stop-thief, joins in the shout, in order to allay suspicion.

It is in the provincial towns that such persons are most successful; the game is seldom played in the metropolis with so much effect; and although some of the tribe have been lately launching forth dashing advertisements in the London papers, it is understood to be with the design of attracting country customers, and overwhelming their dupes with an idea of their _professional_ importance, rather than with the expectation of effecting sales in London.

When they sally forth to “fleece the natives,” who would think of questioning the abilities of such renowned opticians, armed with testimonials, credentials, and certificates! _so_ recommended by the newspapers, and patronized by such eminent practitioners?!!

The fair trader would defend himself at the same time that he unmasked imposture, and protected his customers, if, when his neighbourhood is infested by such mountebanks, he advertised the simple truth. He would assuredly find

“That those base slaves, ’ere yet the fight be done, pack up.”

A few extracts from the advertisements I have inserted in the London and provincial journals may be useful as specimens.

“Spectacle swindlers are now practising deceptions upon the public to an unparalleled extent! They are principally wandering tribes of licensed hawkers, who change their names, or shift their residences, as occasion requires; copy the language of honest men, and puff off, as their own inventions, the very articles, which, without a shade of difference, have been regularly made and sold for above two hundred years. To accomplish their designs of fleecing the public, they resort to the most pompous and extravagant eulogiums on the peculiar virtues of their ‘Saxon Crystals!’ ‘Patent Preservers!’ ‘Tinted Amber!’ and ‘Light Refractors!’ ridiculous terms, which _they have_ invented, and which, embellished with a long list of distinguished names, are calculated to entrap, and impose upon the uninitiated.

“Spectacle wearers, beware! those tricksters, with all their lofty pretensions, are ignorant quacks. Their charges for the trash they foist upon you, are beyond all precedent, enormous!

“The flagrant impositions daily practised on Spectacle wearers, by hawkers and ignorant pretenders, imperatively demand exposure. The boasting charlatans are certainly indebted to the silence of practical opticians for their successful career, since persons requiring optical aid eagerly listen to whoever promises most. To those who have been victimized not another word is necessary to direct their choice, but experience calls on all who need optical remedies to profit by advice, and procure such important scientific instruments only of the known working optician or his resident agent, and thereby insure every advantage—better quality, lower charges, a liberal trial, and an exchange if not approved of.”

* * * * *

“The patronage such individuals quote has never been bestowed, or has been surreptitiously obtained. Mr. C. has documents from celebrated oculists stating this fact most unequivocally, and authorizing him to give publicity thereto. He has the gratification of knowing that his efforts to expose such fraudulent delusions, to defend the fair trader, and to protect the public, have been properly appreciated by the reflecting and intelligent, who perceive the impropriety of countenancing persons who resort to falsehood, misrepresentation, and dishonest artifices; and allow the superior claim of the respectable resident shopkeeper, whose charges are fair, whose desire and interest it obviously must be to supply the article which will suit and to make any exchange or alteration if required.

“Beware of the tricksters who blazon forth their pretended discoveries, in terms which, however absurd and ridiculous, nevertheless catch the attention; and combined with an array of great names, unbounded assurance, and various manœuvring devices, enable them to foist their worthless wares upon purchasers at the most exorbitant prices.

“Such charlatans are the pests of science, and speculators on the credulity of society.

“Mr. C. feels assured that his friends, and the public generally, will remark the necessity there is for some one, practically acquainted with the science of optics, to come forward and state the real facts of the case, at a time when bombast and chicanery,

supported by the most shameless falsehoods, are put forth by itinerant hawkers and pedlars—the pretended discoverers of a superior method of constructing glasses for spectacles. He is anxious to expose such deceptions, and to protect the Spectacle wearer from the gross frauds and impositions continually practised in the sale of Spectacles at enormous prices, although made of the cheapest material, and in the most inferior manner.

“Such Spectacles are productive of endless annoyance to the wearer; and, instead of rendering any assistance are instruments of torture, producing the most serious consequences to the sight, owing to their imperfect construction and the misapplication of their powers to the purposes required.

“Persons requiring Spectacles are earnestly recommended to seek advice and assistance from opticians or their agents, of known respectability and experience, who are capable of judging what kind of lenses are necessary in each particular case: and to avoid those charlatans whose ignorance of optics is only equalled by their impudence, in obtruding themselves into houses, and alarming the occupiers by declaring that they perceive serious defects in their eyes, the formation of cataract, incipient blindness, &c., in order to give an exalted idea of the value of the remedies they offer.”

* * * * *

“T. H., Watch and Clock maker, agent to Cox, optician of London, begs to caution his friends against the impositions of itinerant hawkers, who boast of exalted patronage, wonderful discoveries, and superior skill in optics, professing to suit the sight by merely examining ‘the figure of the eye.’ Such individuals frequently enter into respectable houses, and terrify ladies and gentlemen by declaring that they perceive serious defects in their eyes, and, of course, that nothing can avert the evil but their wonderful Spectacles; sometimes pretending that their only motive in calling is from their wish to relieve mankind from the chances of losing their sight, and to enable them to see as well at fourscore years of age as at twenty, while their main object is to fill their pockets at the expense of those who have fallen into their snare.

“The fallacy of their statements may always be ascertained by the parties taking medical opinion of known value, and consulting a respectable optician.

“It cannot be too generally known that the best glass lenses, constructed on the most accurate principles, suited to the purposes of vision, and worked by hand, can be had of all respectable opticians, at from one shilling and sixpence to three shillings per pair, shewing that there can be no occasion for persons, who require a change of glasses in their spectacles, to pay a guinea or thirty shillings, and give up their old pebbles or glasses into the bargain.

“A trick was practised at Brighton, during the season of 1834, which shews that those certificated gentry do not hesitate at trifles.

“Two Jews, licensed hawkers, inserted glowing advertisements in the Brighton newspapers, couched in their usual bombastic style, but naming _one gentleman_ only as having taken up his residence at Brighton, and stating that he would wait upon the nobility and gentry with a splendid stock of his _wonderful_ and _improved_ Spectacles.

“A man called at the houses of the gentry, made many sales at the usual swindling prices, and disarmed all suspicions by inviting the purchasers to call at his residence, and make any exchange they pleased. In some cases, where the price was objected to, or the parties were taken by surprise, not having suspected that they wanted Spectacles until this _experienced professional optician_ told them they did, they were, notwithstanding imposed upon, ‘for,’ said he, ‘to prove that I am anxious to preserve your sight, which is rapidly leaving you, and cataract is growing in your eyes, these Spectacles, which are five pounds per pair, I will leave you at half-price, and you may pay me the balance at any time.’ This offer appeared so very liberal that it succeeded in several instances, and, it is scarcely necessary to say, left to the hawker forty shillings profit, five pounds being only mentioned to get more easily the smaller sum.

“But the most profitable part of the scheme is yet to be told. Those who purchased soon found that something was wrong—the patent preservers gave great uneasiness to the eyes, which, suffused with tears, seemed to grieve at the simplicity and credulity of their owners. The residence of Mr. —— was besieged with complaining purchasers, who, when their turn arrived, were ushered into the presence of the other of the partners, and as the person who had sold them the Spectacles promised to make any exchange they required, they asked for a pair which would suit their sight, or a return of the money paid. The man they now saw looked at them, and asked, ‘Am I the person who sold you the spectacles?’ ‘Why, no,’ was the reply, ‘I cannot say you were the gentleman, but he was uncommonly like you, and he told me he would exchange the Spectacles if they did not suit.’

“‘Then you had better find him and compel him to do so, for the trash he has sold you will destroy your eyes and ruin your sight. He is an impostor; I know nothing of him.’ ‘Bless me,’ said the disappointed purchaser, ‘what a scandalous shame! what would you advise me to do now, Sir?’

“‘Why, _my_ Spectacles are produced after twenty years of deep study and research, and manufactured, under my own eyes, upon improved principles, yet I only ask fifty shillings per pair; but I am sorry for you and though those you have bought are vile rubbish, I will take them in exchange, and thirty-five shillings for my Patent Tinted Crystals, which are the only Spectacles proper for the eyes.’ Thus the reader will perceive a double imposition was effected. A., after performing his part in the scheme of deception, kept out of the way until B. had completed the fleecing of the nobility, gentry, and public, and in a few weeks the _resident_ opticians were on their way to other places, chuckling at their success, and inventing fresh plans of operation.”

* * * * *

Page after page has been pirated from the works of eminent authors, and palmed upon the public as their own composition; consequently, though the advice may be excellent, the parties from whom it appears to emanate are vile plagiarists, whose _practice_ is quite uninfluenced thereby. When imposture disguises itself in such a plausible form the difficulty of detection is increased, therefore our best security against deception is to transact business with men of known reputation. The resident tradesman has a character for fair and honourable dealing to maintain. He can be appealed to if any exchange or alteration is requisite, and the spirit of fair competition, now abroad, is the best security against overcharge from him; while the itinerant vender and pompous advertiser has to repay himself for such forced and expensive means of getting custom by exacting great prices, pushing off coarse and inferior goods, and practising any dishonest trick rather than not effect a sale of his wares. It may be said, with great truth, “his articles are not cried up because they are things that ought to be desired, but they are desired because they are generally cried up.”

The Liverpool Mercury of Friday, Sep. 15th, 1834, has some remarks on this subject, which, as they are important and appropriate to our purpose, I transcribe:—

“We beg to caution our readers against the arts of all those who profess to supply the public with superior Spectacles; we have been for many years connected with the business, and we can assure the public that the Spectacle glasses sold by the advertising eye quacks are precisely the same as those provided by any respectable optician, the only difference being in the price. The charlatan varies his charge according to the gullibility of his dupes; sometimes he puts up with double the proper and regular price, but more frequently he exacts three or four times more than a regular and honest optician charges. We recollect a once famous optical quack, in London, who made a large fortune by cheating the public. He advertised _his_ superior glasses, which he assured the public were all ground to the true parabolic curve by his own hand, and for each of these glasses he charged four shillings, whilst the working optician who lived a few doors from him, and who furnished him with all his glasses, could only get nine pence for the very article for which the puffing eye doctor charged four shillings. As we knew both the parties we pledge ourselves to the fact, and, in conclusion, we advise the public to have nothing to do with quacks, whether they be scientific quacks, who are plentiful enough, or other quacks, who swindle people out of their health and cash at the same time.”

CHAPTER VIII.

“Who will, for him, may boast of sense, His better guard is impudence.”

In the early part of the present year I addressed letters to several gentlemen who figure in the list of patrons to the advertising Spectacle quacks, and enclosed a copy of the advertisements in which their names had appeared as giving unqualified approval to the trickster’s _invention_.

From the specimens I have given of such advertisements it is unnecessary to give a verbatim copy again here; and as the truths which this correspondence elicits apply to one and all of the puffing tribe, I have omitted the names of the individuals particularly alluded to, my object being to expose a _system_ of villainy, and not to denounce _one_ or _two_ rapacious creatures, while the rest of the clique escape detection.

Therefore, although many of the remarks in these pages may seem to have only a local or particular reference, they are applicable to the whole tribe of _locusts_, and describe the species too definitely to admit of mistake. The characters sketched are not caricatures, but, unfortunately for the eyes of her majesty’s lieges, really exist _in propriâ personâ_.

Feeling assured that the Duke of Wellington would rejoice to see an exposure of such tricksters, I forwarded to him a copy of Spectacle Secrets, and the following acknowledgment was promptly returned:—

Walmer Castle, _Nov. 11, 1838_.

The Duke of Wellington presents his compliments to Mr. Cox, and has received his letter and the work referred to: he is much obliged to Mr. Cox for the communication.

* * * * *

Copy of a Letter to FREDERICK TYRELL, Esq.

SIR,—The advertisement enclosed frequently appears in the daily and weekly newspapers, to which, as your name is attached, I beg to direct your attention, and solicit an answer to the following questions at your earliest convenience.

1st.—Have you proved the superior efficacy of the Spectacles, (as stated in the advertisement), and consider they merit your unqualified approbation?

2nd.—Will you oblige me by stating what peculiar advantages you consider them to possess over the usual Spectacles, manufactured by the London opticians?

3rd.—Does your approval extend to all the Spectacles sold by the advertiser, or to those which he designates Amber Spectacles only?

I remain, Sir, yours obediently, GEORGE COX.

To Frederick Tyrell, Esq.

* * * * *

Mr. TYRELL'S Reply.

17, New Bridge Street, Blackfriars. _January 29th, 1838._

SIR,—In reply to your letter respecting Mr. —— I have to state, First, That I am not acquainted with any institution which is designated "The Royal Eye Infirmary," to which he states that he is optician. The Royal Ophthalmic Hospital, in Moorfields, is sometimes so called, but Mr. —— is not optician to that institution.

Secondly, That Mr. —— has not any permission from me to make use of my name in advertisements, as approving of any glass, spectacles, or other articles he may either manufacture or sell. And thirdly, That I do _not_ consider his glasses to be in any respect superior to those manufactured by other persons in the trade.

You are at liberty to make use of this communication in any way you deem proper to counteract Mr. ——'s advertisements.

I remain yours respectfully, FREDERICK TYRELL.

To Mr. George Cox.

* * * * *

J. Hodson, Esq., consulting Oculist to the Eye Infirmary, Birmingham, resolved upon coming to London to give me his disclaimer, rather than incur any chance of misrepresentation from an unjustifiable use being made of his signature, he being an entire stranger to me before I addressed him upon this subject.

He authorizes me to state that Mr. —— has no authority or right whatever to make use of his name. About four years since a man came to his surgery, and introducing himself as the inventor of roseate tint preservers and amber spectacles, showed him a pair in silver frames, and, expatiating upon their wonderful properties, mentioned the names of several leading surgeons and oculists who had inserted their signatures in a book which he handed to Mr. Hodson, who, without suspecting the design of the knave, added his to the list, for the same reason, he said, that folks do so at a watering place, a library, or as having visited or seen some particular exhibition—in fact, because it was customary to do so. Four or five days afterwards the same individual called again, apparently in great haste, and requested Mr. H. to lend him two sovereigns, as he had immediate occasion for that sum. He produced a pair of

amber spectacles, and said, “I will leave these as security until I return the money.” Mr. H. began now to suspect the fellow, and guessed it to be very unlikely that he would trouble himself to redeem the Spectacles (worth about twelve shillings) if he succeeded in raising two pounds upon them; he therefore referred him to a pawnbroker in the neighbourhood, whose business it was to enter into such arrangements, which were, clearly quite foreign to his, Mr. H.’s practice.

Mr. Hodson has ever since regretted having (though inadvertently) given his signature, which, as the reader will perceive, is solicited as a mere matter of form, and is then made the most unwarrantable use of, involving the parties in many dilemmas, and exposing them to the ridicule and reprehension of every intelligent observer.

The fact is, if one signature of an eminent person can be procured by dint of false representation or plausible pretence, the rest follow as a matter of course; thus Mr. Hodson signed his name, seeing that some of the “heads of colleges” were there inscribed. Mr. Soden, of Bath, gave his signature because Mr. Ledsam had given his; and Mr. Ledsam signed because Mr. Hodson had done so.

Mr. Alexander, Oculist to the Royal Family, was waited upon by one of the crafty crew, whose object was to get his signature at all hazards. The fellow fawned and entreated, but was sternly resisted by Mr. A. who showed him the door, and declared, if he presumed to make use of his name, in his quack advertisements, he would set a solicitor to work immediately.

Copy of a Letter from ROBERT KEATE, Esq., Surgeon in Ordinary to Her Majesty.

Albemarle Street, _July 17, 1838_.

SIR,—Although I do not consider myself bound to reply to the questions put to me by you, being in utter ignorance of the use which you propose to make of my answer; yet I can have no hesitation in saying that I think Mr. —— has been guilty of an unpardonable liberty in publishing my name, without my sanction, and more especially in appending it to the document (a copy of which you sent to me), and to which I have never affixed my signature. I was requested to look at M ——’s amber spectacles, and I saw no others; and looking through them on a day when the sun shone brightly, they appeared to me to soften the light more than crystal or pebbles; and seeing the names of many eminent surgeons and oculists attached to various certificates, I wrote and signed what I have stated above, and I believe no more; namely, that the amber spectacles seemed to _soften the light_ more than the pebbles.[16] I am not aware of having seen any other sort; and certainly I have not ventured to sign my _approval_ of these, or of any others.

I am, Sir, your obedient servant, ROBERT KEATE.

To Mr. George Cox.

I could give the disclaimers of other gentlemen who have been trepanned into giving their signatures, which are afterwards so pompously paraded by the testimonialed and certificated adventurers; but these will suffice to illustrate the working of the system.

“A wise physician, skill’d our wounds to heal, Is more than armies to the public weal.”—POPE.

I cannot but feel gratified, that this correspondence, while it has substantiated my arguments, affords an opportunity for those gentlemen to explain the real truth of the matter, and to exonerate themselves from the contaminating connexion, which appeared to place their reputation for that “quality called honesty” in jeopardy.

I have received several impromptu effusions from humorous correspondents in different parts of the kingdom, where I have been and unmasked the impositions of spectacle cheats. One says—

“They _make_ not spectacles, you say; With that I can’t agree, Both wife and I have worn their trash, Now spectacles are we.”—QUIZ.

Another—

“A celebrated chemist has ascertained, by very accurate analysis, that there is enough brass in the countenances of the spectacle men of Duke’s Place and Petticoat Lane to make spectacle-frames for all the spinsters in the neighbourhood.”—SATIRIST.

I have, of course, laid myself open to the furious and vindictive hostility of those quacks, whose nefarious practices are exposed, and whose career will be checked in proportion as this treatise is circulated and dispassionately perused. But, secure of the approbation of all my readers who will avail themselves of the information contained in these pages, I may conclude with

satisfaction, since

Friends I have made whom envy must commend, And not one foe whom I would wish a friend.

THE END.

R. COTTLE, PRINTER, BASINGSTOKE.

FOOTNOTES:

[16] When the eyes are distressed and overwhelmed with light, _any_ shade or screen is viewed with satisfaction. Coloured glasses “soften the light” more naturally, and present to the eye equal and parallel surfaces: parasols, veils, and even opaque substances, may thus be said to shield the eye, and “modify bright and strong light,” but it would be as ridiculous to consider these as fit mediums for the ordinary purposes of vision, as it is to select amber for the purpose.

Preface.

Our reasons for writing this book will be explained by the book itself. We desire here gratefully to acknowledge the help of several friends who have considerably facilitated our task. Our thanks are due to Major R. G. ROWS, M.D., R.A.M.C., for his unfailing interest, encouragement and help; to Captains W. H. R. RIVERS, M.D., F.R.C.P., F.R.S., and J. W. ASTLEY COOPER of the R.A.M.C., and Mr. E. GLEAVES, M.Sc., for their valuable suggestions and assistance in the preparation of the manuscript; to Captain W. E. SAWERS SCOTT, M.D., R.A.M.C., Dr. ALBERT HOPKINSON and Mr. W. PERCY STOCKS, F.R.C.S., of Manchester, for help in other ways; and to our colleague, Professor H. BOMPAS SMITH, for reading the proofs and helping us to eliminate some of the more glaring literary defects. To the Editor of the _Lancet_ we are indebted for permission to use part of an article written by one of us. The stream of requests for fuller information and explanation that poured in upon the author of that article made the writing of this book an unavoidable duty.

G. E. S. T. H. P.

THE MEDICAL SCHOOL, THE UNIVERSITY, MANCHESTER.

20th April, 1917.

Introduction.

Some account of the reasons for the appearance of this book is due to the reader. During the last year we have been asked repeatedly, both by members of the medical profession and the lay public, to write a simple non-technical exposition of the ascertained facts of that malady, or complex of maladies, for which we have adopted the official designation “shell-shock.” Until recently such an attempt would have been premature and largely speculative. But it is now possible to collate the medical reports, not only from our own army, but also from those of France and Russia. Valuable and suggestive data have, furthermore, been obtained from such of the German medical journals as have reached us. The facts described in the various accounts which we have seen are in close agreement. The conclusions in this book, therefore, are not based upon our experience alone.

Our object in thus publishing a brief and simple description of these facts is twofold: first, to make them available to those who have neither the time nor the special knowledge necessary for consultation of the medical journals; secondly, to call attention to the obvious significance of these truths for the future welfare and happiness of the nation.

It might seem that to publish a book on this subject at such a time is merely to irritate existing wounds. The topic is painful; perhaps one of the saddest of the many grievous aspects of the war. But a condition exists at present which is immeasurably more painful—the exaggerated and often unnecessary distress of mind in many of the sufferers and their friends, which arises from the manner in which we, as a nation, have been accustomed to regard even the mildest forms of mental abnormality. Of all varieties of fear, the fear of the unknown is one of the greatest. Not the least of the successful work performed in the special hospitals during the war has been the dispelling of this fear by helping the sufferer to understand his strange symptoms (many of which are merely unusual for the patient himself) and, in the light of this new self-knowledge, to win his own way back to health.

It is because we believe that a similar probing of the _public_ wound—the British attitude towards the treatment of mental disorder—though painful, is justifiable and necessary, that we have written the concluding chapters of this book. For it cannot be too strongly urged that the shifting and unstable blend of apathy, superstition, helpless ignorance and fear with which our own country has too long regarded these problems is rapidly becoming our exclusive distinction. It must be realised that America, France, Germany, and Switzerland have long ago faced the problem in the only practical way—the scientific one. And to the long list of sciences which we all agree must be cultivated more assiduously after the war should be added—but not at, or even near, the end—psychiatry, the science of the treatment of mental disorders.

Not patriotic motives alone urge this reform, but common sense and common morality. For shell-shock has brought us no new symptoms. Its sole ground of difference from other disordered states of mind lies in its unusually intense and wide-spreading causes. The problems of shell-shock are the every-day problems of “nervous breakdown.” They existed before the war, and they will not disappear miraculously with the coming of peace. The war has forced upon this country a rational and humane method of caring for and treating mental disorder among its soldiers. Are these signs of progress merely temporary? Are such successful measures to be limited to the duration of the war, and to be restricted to the army? Germany has applied them for years to the alleviation of suffering among her civilian population, with a success which has made her famous—outside England. Can we be content to treat our sufferers with less sympathy, insight and common-sense than Germany?

It is at this time, while our country is anxiously considering how best to learn the lessons of the war, that we wish to call attention to one of these lessons which is in danger of being overlooked.

CHAPTER I.

The Nature of Shell-Shock.

A French doctor has said, “Il n’y a pas de maladies; il n’y a que des malades.”[1] Whatever may be the general validity of this statement, it is undoubtedly true of the nerve-stricken soldier. Every case is a case by itself, and as such it must be considered by anyone, be he layman or doctor, who is interested in its nature and treatment. For the troubles displayed in the many disorders classed under the official title shell-shock are extraordinarily numerous and different, and their removal necessitates a similarly varied repertoire of “opening moves” on the part of the physician.

Although the term shell-shock has been applied to a group of affections, many of which cannot strictly be designated as “shock,” and into the causation of which the effect of the explosion of shells is merely one of many exciting factors, this term has now come to possess a more or less definite significance in official documents and in current conversation. It is for this reason that we have chosen to use it rather than the more satisfactory, but less widely employed term, “War-Strain.” The reader will, therefore, understand that whenever the term shell-shock appears in these pages, it is to be understood as a popular but inadequate title for all those mental effects of war experience which are sufficient to incapacitate a man from the performance of his military duties. The term is vague; perhaps its use implies too much; but this is not altogether a disadvantage, for never in the history of mankind have the stresses and strains laid upon body and mind been so great or so numerous as in the present war. We may therefore expect to find many cases which present not a single disease, not even a mixture, but a chemical compound of diseases, so to speak. In civil life, we often meet with cases of nervous breakdown uncomplicated by any gross physical injury. We are scarcely likely, for example, to meet it complicated by gas poisoning and a bullet wound. Yet such combinations as these—or worse—are to be met with in the hospitals every day.

This is perhaps an opportune place to point out a significant popular misunderstanding concerning the nature of such maladies as we shall discuss in this chapter. A common way of describing the condition of a man sent back with “shock” is to say that he has “lost his reason” or “lost his senses.” As a rule, this is a singularly inapt description of such a condition. Whatever may be the state of mind of the patient immediately after the mine explosion, the burial in the dug-out, the sight and sound of his lacerated comrades, or other appalling experiences which finally incapacitate him for service in the firing line, it is true to say that by the time of his arrival in a hospital in England his reason and his senses are usually not lost but functioning with painful efficiency.

His reason tells him quite correctly, and far too often for his personal comfort, that had he not given, or failed to carry out, a particular order, certain disastrous and memory-haunting results might not have happened. It tells him, quite convincingly, that in his present state he is not as other men are. Again, the patient reasons, quite logically, but often from false premises, that since he is showing certain symptoms which he has always been taught to associate with “madmen,” he is mad too, or on the way to insanity. If nobody is available to receive this man’s confidence, to knock away the false foundations of his belief, to bring the whole structure of his nightmare clattering about his ears, and finally, to help him to rebuild for himself (not merely to re-construct for him) a new and enlightened outlook on his future—in short, if he is left alone, told to “cheer up” or unwisely isolated, it may be his reason, rather than the lack of it, which will prove to be his enemy. And nobody who has observed the hyperæsthesia to noises and light in the nerve-hospital, nobody who has seen the effects upon the patients of a coal dropping unexpectedly out of the fire, will have much respect for the phrase, “lost his senses.” There exist, of course, cases of functional blindness, deafness, cutaneous anæsthesia and the rest, but the majority of the nerve patients show none of these disorders and recovery from them is often rapid.

In a word, it is not in the intellectual but in the _emotional_ sphere that we must look for terms to describe these conditions. These disturbances are characterised by instability and exaggeration of emotion rather than by ineffective or impaired reason.[2] And as we shall see later, in the re-education of the patient, the physician is compelled continually to take this fact into account.

As we have pointed out, every nerve-stricken soldier presents a case by itself. Slavish adherence by the physician to one of the classical names or labels used in diagnosis usually spells failure. The patient must be approached _without prejudice_, and the doctor who wishes to be of real help to him must make up his mind to examine and ponder over the sufferer's mental wounds with as much, nay, even more—care and expenditure of time than would be given to physical injuries. A mere cursory inspection in the course of the formal ward visit is a solemn farce, if it pretends to be a serious attempt to cure the mentally afflicted.

A man standing at "attention" by the side of his bed, surrounded by his comrades and faced by the medical officer, the military sister, and perhaps even by other members of the staff may volunteer the information that he is sleeping badly. But this imposing procession and cloud of witnesses is scarcely conducive to the production of any further evidence as to the cause of his insomnia. For of those causes even pre-war experience makes it possible to assert that their name is legion, and their character often of an exceedingly intimate and private nature.

The formal visiting of patients in the wards, while adequate for the care of physical injuries (which can be subsequently attended to by trained nurses and sisters) and necessary for administrative and disciplinary purposes, is insufficient for "mental cases." It is with this fact in mind that the military authorities have instituted special hospitals in which more detailed attention may be given to the latter class of patients. In these institutions the soldier may have private interviews with his medical officer, and the history of the trouble can be unravelled in conversation. _It is only in this way that any scientific insight into a case of mental disorder can be obtained._

A short time spent in such interviews, or even the perusal, by the uninitiated, of the papers already published in the _Lancet_, _British Medical Journal_, and elsewhere[3], will convince one of the immense complexity of these unusual mental conditions, and moreover, of the absolute necessity of obtaining and understanding the patient's past history, before and during the war. A dozen cases sent back from the front as shell-shock may prove to possess not a single feature in common—except the fact of the shell explosion. And this, as has been pointed out, may be but the "last straw."[4] The patient often discloses in the first interview the fact that he was displaying all his present symptoms _before_ the arrival of the particular shell which laid him out.

It is now possible to attempt a brief sketch of the typical conditions which give rise to some of the chief varieties of shell-shock. Let us take a common case; that of the patient who is returned to this country, figuring in the casualty lists under the terse and businesslike military formula, "shock, shell."

For various reasons, which the reader will easily supply, we choose to present a composite picture of the history of such a soldier. Not all the conditions described here need necessarily have operated in any one case taken at random, but we shall err, if at all, on the side of understatement. The correctness of the description may be checked by a reference to the papers already mentioned.[5]

We must first try to conceive the experiences of the soldier before the occurrence of the knock-out blow, so far as they bear on his present condition. Let us suppose that his period of training has made him physically and mentally fitter than he had ever been before, that no military causes of anxiety or fear, such as the experience or the anticipation of being torpedoed on the outward voyage, have operated to any noteworthy extent in his case. He enters the trenches in first-class condition. The duration of his stay there, provided he is not wounded, or attacked by any bodily illness, will depend from that time forward upon the nature, duration, intensity and frequency of the emotion-exciting causes, and upon himself. By that all-inclusive word "himself" we mean to signify chiefly his temperament, disposition and character.[6]

It must be remembered that one of the greatest sources of breakdown under such circumstances is intense and frequently repeated emotion.[7] By this is meant not only experiences of fear or of sympathy with suffering comrades, in short, those conditions the manifestations of which might cause the man in the trenches to be spoken of as "emotional," but also other mental states associated with general excitement, anxiety, remorse for major or minor errors, anger, elation, depression and that complex but very real state, the fear of being afraid. (The more definite terms of technical psychology are not used here, as it is considered wiser to employ popular language.)

The soldier may be subjected to intense emotional stimuli of this kind for days or weeks without relief. And whereas to the mental sufferer in civil life sleep often is vouchsafed, "setting him on his feet" to continue, more or less effectively, the struggle next day, to

the soldier sleep may be impossible, not necessarily because of his excited mental state, but simply from the lack of opportunity or the disturbances going on about him. In course of time this loss of sleep from external causes may easily set up bodily and mental excitability, which in its turn acts as a further cause of insomnia. The usual mental conditions associated with loss of sleep then rapidly supervene: pains and unpleasant organic sensations, hyperæsthesia, irritability, emotional instability, inability to fix the attention successfully upon important matters for any length of time, loss of the power of inhibition and self-control.[8]

These symptoms, troublesome enough in civil life, become positively dangerous to the man in the trenches, especially if he is in a position of responsibility. In that case his standing as officer or N.C.O. merely adds to his mental distress. Bodily hardship, such as exposure to cold and wet, hunger, and the irritation from vermin, obviously aggravates the disorders we have described.

We must not suppose, however, that the man who is experiencing some or all of these mental and bodily conditions is at this period necessarily displaying any obvious _outward_ signs of his trouble. There may be no tremor, no twitchings, no loss of control of the facial or vocal muscles which would indicate his state even to his neighbours. He may, for a long time, “consume his own smoke.” And during this process he may even appear to his comrades to be steadier and more contemptuous of danger than before. Dr. Forsyth[9] has cited some dramatic incidents, in which officers who imagined that their instinctive fear was becoming apparent to the men under their command took unnecessary risks in order to impress these men with the idea that they were not afraid.

It must be understood that this suppression of the external manifestations of an emotion such as fear is but a partial dominance of the bodily concomitants of that emotion. The only changes which can usually be controlled by the will are those of the voluntary or skeletal muscular system, not those of the involuntary or visceral mechanism. While no signs of fear can yet be detected in the face, the body, limbs or voice, these disturbances of the respiratory, circulatory, digestive and excretory systems may be present in a very unpleasant degree, probably even intensified because the nervous energy is denied other channels of outlet.[10]

The suppression of fear and other strong emotions is not demanded only of men in the trenches. It is constantly expected in ordinary society. But the experience of the war has brought two facts prominently before us. First, before this epoch of trench warfare very few people have been called upon to suppress fear continually for a very long period of time. Secondly, men feel fear in different ways and in very various degrees.

The first fact accounts for the collapse, under the long continued strain of trench warfare, of men who have shown themselves repeatedly to be brave and trustworthy. They may have felt intense emotions, obviously not of fear alone, for a long time without displaying any signs of them. But suppression of emotion is a very exhausting process. As Bacon says, “We know diseases of stoppings and suffocations are the most dangerous in the body; and it is not much otherwise in the mind.”

The second fact mentioned above is of great importance in the consideration of our problem. There are undoubtedly men who seem to be immune to fear of the dangers of warfare. But to them we can scarcely apply the adjective “brave.” The brave man is one, who, feeling fear, either overcomes it or refuses to allow its effects to prevent the execution of his duty.

Other emotional states however, besides fear, arise and require suppression. The tendency to feel sympathetic pain or distress at harrowing sights and sounds, disgust or nausea at the happenings in the trenches, the “jumpy” tension in face of unknown dangers such as mines—all these, like fear, are or have been biologically useful under natural conditions and, like it, are deeply and innately rooted in man. But the unnatural conditions of modern warfare make it necessary that they shall be held in check for extraordinarily long periods of time.

The impossibility of regarding modern methods of warfare in the same light as natural and primitive means of fighting appears very clearly when we consider the instinctive and emotional factors involved in the two sets of circumstances. In natural fighting, face to face with his antagonist, and armed only with his hands or with some primitive weapon for close fighting, the uppermost instinct in a healthy man would naturally be that of pugnacity, with its accompanying emotion of anger. The effect of every blow would be visible, and the intense excitement aroused in the relatively short contest would tend to obliterate the action of other instincts such as that of flight, with its emotion of fear. But in trench warfare the conditions are different. A man has seldom a personal enemy whom he can see and upon whom he can observe the effects of his attacks. His anger cannot be directed intensely night and day against a trench full of unseen men in the same way in which it can be provoked by an attack upon him by an individual. And frequently the assaults made upon him nowadays are impersonal, undiscriminating and unpredictable, as in the case of heavy shelling. One natural way is forbidden him in which he might give vent to his pent-up emotion, by rushing out and charging the enemy. He is thus attacked from within and without. The noise of the bursting shells, the premonitory sounds of approaching missiles during exciting periods of waiting, and the sight of those injured in his vicinity whom he cannot help, all assail him, while at

the same time he may be fighting desperately with himself. Finally, he may collapse when a shell bursts near him, though he need not necessarily have been injured by actual contact with particles of the bursting missile, earth thrown up by its impact, or gases emanating from its explosion. He may or may not be rendered unconscious at the time.[11] He is removed from the trenches with loss of consciousness or in a dazed or delirious condition with twitchings, tremblings or absence of muscular power.

Upon recovery of consciousness, which may take place after periods varying between a few minutes and a few weeks, the immediate disorders of sensation, emotion, intellect, and movement, are often very severe. It may be presumed that at the beginning of the war they must have appeared far more serious to most of the doctors who saw them in their early stages than they would now. This speculation is suggested by the evidence of the case-sheets sent with the men from France in the early period of the campaign. Such diagnoses as “delusional insanity,” and other similar terms taken from the current classifications of advanced conditions of insanity, appear very frequently as descriptions of cases which on arrival in England had almost entirely lost every sign of mental unusualness. In fact, one of the most cheering aspects of work amongst this type of case has been the rapidity with which men who have presented quite alarming symptoms have subsequently recovered.

It may seem almost unnecessary to enumerate the bizarre phenomena which constitute the immediate results of shell-shock, for our newspapers have naturally seized upon such unusual details and have made the most of their opportunities in this direction. But the reader will obtain a clearer idea of the facts if they are catalogued once more.

The most obvious phenomena are undoubtedly the disturbances of sensation and movement. A soldier may be struck blind, deaf or dumb by a bursting shell: in rare cases he may exhibit all three disorders simultaneously or even successively. It should be added that these troubles often vanish after a short space of time, as suddenly and dramatically as they appeared. Thus one of the blinded soldier survivors of the _Hesperian_ recovered his sight on being thrown into the water. Other blind patients have had their sight restored under the action of hypnosis. Mutism is often conquered by the shock of a violent emotion, produced accidentally or purposely. Examples of such “shocking” events taken at random from our experience were the sight of another patient slipping from the arms of an orderly, the “going under” chloroform, the application of a faradic current to the neck, the announcement at a “picture house” of Rumania’s entry into the war (this cured two cases simultaneously), and the sight of the antics of our most popular film comedian. The latter agency cured a case of functional deaf-mutism, the patient’s first auditory sensations being the sound of his own laugh.

The muscular system may be affected in an equally striking manner. Contractures often occur in which a man’s fist may be immovably clenched for months; or his back may be bent almost at right angles to his lower limbs, there being in neither case any bodily change discoverable by the neurologist which can account for such a condition. These contractures, though curable, often prove very obstinate, and at present their nature remains somewhat of a mystery. Other distressing and long continued disturbances take the form of muscular twitchings and tremors or loss of power in the limbs.

Not every nerve-case, however, presents such striking and objective signs as those which we have just been describing. The _subjective_ disturbances, which are apt to go undiscovered in a cursory examination of the patient, are frequently more serious than the objective,[12] and are experienced by thousands of patients who to the mere casual observer may present no more signs of abnormality than a slight tremor, a stammer, or a depressed or excited expression. These afflictions: loss of memory, insomnia, terrifying dreams, pains, emotional instability, diminution of self-confidence and self-control, attacks of unconsciousness or of changed consciousness sometimes accompanied by convulsive movements resembling those characteristic of epileptic fits, incapacity to understand any but the simplest matters, obsessive thoughts, usually of the gloomiest and most painful kind, even in some cases hallucinations and incipient delusions—make life for some of their victims a veritable hell. Such patients may have recovered from sensory or motor disturbances and yet may suffer from any or all of these afflictions as a residuum from the original “shock-complex;” they may suffer from them as a complication of the discomfort attending upon a wound or an illness, or, on the other hand, they may have no overt bodily disorder: their malady then being usually given the simple but all-inclusive (and blessed) description “neurasthenia.”

Now the happiness and welfare of such men obviously is bound up to no small extent with the character of the hospital or hospitals (for the plural number is commonly to be used in writing the history of these patients) to which they are sent. In the general military hospitals the medical officers have neither the time nor, in many cases, the special knowledge, necessary to deal with cases of this kind. Such patients may recover of themselves without any treatment, but a large number of them tend to get worse, and if they are left without attention their symptoms are apt to become stereotyped into definite delusions and hallucinations. Moreover, in a general ward such men may become a constant source of disturbance and annoyance to other patients and to the nurses. One of

the symptoms of their illness is a morbid irritability; they tend to become upset and to take offence at the merest trifles[13]—and this leads to trouble with patients, nurses, and the medical officers responsible for discipline. But if special consideration is shown them by the nurses the other patients are apt to misunderstand it and even to complain of favouritism. In other words, when mixed with wound-cases in a general hospital, these nervous patients are apt to be regarded as a nuisance—which is bad for them and for the proper working of the hospital. Another consideration, too, is that the subjection of such men to irksome regulations of military discipline, and the usual penalties for infringing them, is often so potent a factor in producing disturbances as to be quite fatal to any hope of amelioration.

These considerations have led the military authorities to establish special hospitals for nerve-cases.[14] In such institutions the patients can be nursed and attended to by a staff which, being used to the idiosyncrasies of such illnesses can make conditions more suitable to them.

A man's particular nervous malady is likely to be of common occurrence in the nerve-hospital; it does not render him conspicuous, and therefore an object of fussy solicitude, galling pity, or suspicious contempt, as is too often the case in other institutions. If unwounded, he need not suffer the taunt of "having nothing to show" as his reason for staying in hospital. Further, while in the special hospital, more importance is attached to some of the patient's symptoms, less disturbance is produced by others. The occurrence of a "fit" is viewed by the rest of the men in this class of hospital in a truer perspective, and the patient does not find himself a nine-days' wonder, as he so easily may do in a small auxiliary hospital full of straightforward wound cases.

Up to this point we have discussed the various troubles subsumed under the term shell-shock in what may be termed its initial and middle stages. In the middle stage, the patient having recovered from the severe and acute symptoms constituting the former phase, is left with a motley residuum of troubles, the chief of which we have enumerated on pages 12, 13. In distinguishing between this middle stage and that which follows it, we may perhaps ask the reader to assist us by recalling the difference between a mechanical mixture and a chemical compound. In the former the ingredients of the mixture remain unaltered and unaffected by the proximity of other substances, as for example when sugar is mixed with sand. In the compound, on the other hand, chemical action and reaction occur between the components so that not one of the substances is immediately recognisable in the complex, as for example when carbon, hydrogen and oxygen combine to form alcohol, which resembles none of them.

Now it would be distorting the facts of mind to suggest that while the third stage of shell-shock is a compound (as it undoubtedly is) the middle stage is a mixture. For the very essence of mind is its compound nature. But what we wish to point out is that in this middle stage the abnormalities have had very little time to react upon each other, with the result that there is some resemblance to a state of mixture, the phenomena existing temporarily side by side, so to speak. In this stage a patient may be troubled simultaneously by several unusual mental occurrences, such as terrifying dreams during very light sleep, loss of memory for certain periods of his past, and inability to understand or to carry out complex orders. For a short time in his "bowled-over" state he may be worried by the separate attacks, of these various troubles at different periods of the day and he may be too overwhelmed to try to understand or to attempt to see relations between them. This state of mind, in which the patient is still his "old self," though a somewhat overturned self, resembles the mechanical mixture in our illustration. The reader may obtain some idea of this condition if he recalls any one day in his own experience when "everything seemed to go wrong"; when at one moment he was turning to face this difficulty, at another, that, but still retained to a great extent his usual attitude towards the world.

As has been pointed out, however, the state of "mechanical mixture" is utterly alien to the normal mind, which tends rapidly to interpret, in the light of its own experience, and to integrate as far as possible, its events, however incongruous they may be. The mind cannot, for any length of time, allow a new experience to remain strange or undigested. It must gather in and assimilate that event to the systematised complex which we call its own past experience. It follows that the ultimate result upon any particular mind of a new experience, if it be of a personally significant nature, will depend almost entirely upon the past history of that mind.

Thus for example the question whether the patient can or cannot satisfactorily stand up to his new troubles will be determined not only by his disposition, temperament and character, but also by his previous personal experience.

It is thus obvious to anyone who gives the matter any serious consideration, that the manifestation of a severe psychical shock must necessarily be determined in a large measure by the nature of the mind upon which the injury falls. It would be idle to pretend therefore, that, in diagnosis, the story of the patient's past experience can be left out of account, for the manifestation of the injury will obviously depend largely upon the individual patient's "mental make-up."

Faced by the existence of a number of unusual mental phenomena the patient will inevitably succeed in time in inventing for himself, explanations of their co-existence. This “rationalisation,”[15] as it is called, is a perfectly normal process which is constantly going on in every individual, yet it plays a great part in complicating the mental disorders of the middle stage, and thereby intensifying the patient’s ultimate distress. For instance, he may not be more than temporarily disturbed by the unusual experiences we have mentioned[16] if they assail him separately. But, given time, he will soon begin to connect their appearances, and will argue to himself that these phenomena can have only one meaning: that he is mad or rapidly becoming so. And in this completely erroneous procedure he will be aided and abetted, not only by his own ignorance of the relation of mental normality to abnormality, but also by the general tendency of the uneducated to class everything unusual in the mental sphere as “mad.” Once he is convinced that he is in this state he may easily lose all hope of getting better, thereby increasing enormously the gravity of his case. Completely illogical, but to him entirely satisfactory explanations of his condition will then multiply.

As we have mentioned, this rationalisation is no unusual phenomenon in ordinary life. It will be clear to anyone who gives the question a moment’s thought that few of the non-scientific[17] beliefs held by even a highly educated person have ever been logically reasoned out from fundamental principles. In fact such principles frequently cannot be reached, for the very good reason that they have never been consciously conceived by the individual. One’s views on religion, politics, or the relations and rights of the sexes may exhibit in their outer casings a semblance of rational structure: their core, however, is not reason but emotion. As James expresses it:—

“In its inner nature, belief or the sense of reality is a sort of feeling more allied to the emotions than to anything else ... reality means simply relation to our emotional and active life. This is the only sense which the word ever has in the mouths of practical men.... Whenever an object so appeals to us that we turn to it, accept it, fill our mind with it, or practically take account of it, so far it is real for us and we believe it. Whenever, on the contrary, we ignore it, fail to consider it or act upon it, despise it, reject it, forget it, so far it is unreal for us and is disbelieved.... Whatever things have intimate and continuous connection with my life are things whose reality I cannot doubt.”[18]

Few people, however, realise this truth so clearly, or express it so lucidly, as Professor James. Often we believe that we are logically convinced when in reality we have been convinced first, and have invented reasons for our conviction afterwards. But many of our beliefs and attitudes have been implanted in us in childhood or early youth by processes which could not by the wildest stretch of imagination be called logical. And not the least important of those beliefs are those held by the average Briton with regard to insanity.[19]

For the patient, then, his mental troubles, having intimate and continuous connection with his life, become very real indeed. But the longer he is left alone to “cheer up,” the longer he broods over his troubles in isolation, the longer he is allowed to build theories upon his inadequate and inaccurate data, the more intimately and continuously connected with his life will the abnormalities become. They may come to be so integrated with each other that his very personality becomes tinged. Then he is no longer a normal person battling with his separate enemies, but one who has made terms, and those often disastrous ones, with his closely allied foes. An attempt to cure him at this stage will then necessitate the analysis of a highly complex compound, while in the early and middle stages merely the attack upon separated elements is necessary.

We are concerned at present with the facts of shell-shock, but this is perhaps a suitable place in which to deal with an opinion about this set of phenomena, which is not uncommon, especially perhaps in people above military age. That judgment, expressed sometimes bluntly, but oftener in a more subtle fashion, is that shock or neurasthenia are polite names for nothing else but “funk.” It is not easy to take a dispassionate view of this question, but to persons holding this opinion the following points are worthy of consideration.

First, the most severe and distressing symptoms occur to a surprising extent in the case of those patients whose past history shows that, far from possessing even the normal quota of timidity, they had been noted for their “dare-devilry” and had been specially chosen as despatch-riders, snipers and stretcher-bearers in the firing line. Secondly, it is not uncommon for patients to ask to be sent back to duty because they feel that they have been too long with nothing to do, while it is quite obvious to the doctor that they are as yet unfit to bear any great strain. Thirdly, the seasoned regular, officer or N.C.O.,[20] as well as the young soldier of only a few months’ service may display precisely the same symptoms as those we have described. Such men have frequently been in the army for many years, and have fought on previous occasions with great success. Their strength of mind and body has been demonstrated over and over again, yet at last they have broken down. And they manifest the greatest concern at their unusual symptoms.

It will be readily granted, of course, that there exist among the nerve patients returned from the front cases in which there is genuine fear of the war, arising from memories of the experiences which they have undergone. Even this state of mind, however, is usually expressed by the patient in some such phrase as “I don’t want to go back, but I’ll go quite willingly if I’m ordered to.” It should not be forgotten, moreover, that not a small number of instances are known in which these men prove to have made repeated attempts at enlistment after having been rejected several times, or even discharged from the army, changing their medical examiner until they have succeeded. One case, presenting a great number of the symptoms of shell-shock in a very intense form, including, beside the ordinary neurasthenic troubles, blindness, deafness, and mutism at successive times, was that of a man who had been discharged from the army as medically unfit and had re-enlisted.

Two cases may be quoted here in illustration of some of these assertions:

The first is that of a non-commissioned officer who went through the initial eleven months of the war in France and Flanders, was subjected to every kind of strain, physical, mental and moral, which that stricken field provided; and in addition was wounded twice, gassed twice, and buried under a house, on all five occasions being treated in the field ambulance and then returning to the trenches. After all this experience he had not qualified for sick leave, but was granted five days ordinary leave to return home, apparently in a good state of health. After reaching England and while waiting for a train in the railway station, he suddenly collapsed, became unconscious, and for months afterwards was the subject of severe neurasthenia. Apparently at the front the excitement, the sense of responsibility and especially the example that he felt he should set his men, seem to have kept him right. These stimuli removed, he broke down. The whole of his trouble seemed to be due to the dread lest on his return to the front, the added responsibilities which would fall upon his shoulders (because most of his own officers had been killed and there would be new men to replace them) might be too much for him. His intelligence seemed (to himself) to have become numbed by his experiences, and he became conscious of the unreliability of his memory and of his inability to understand not only complex orders, but, as he put it, “even the newspapers.” It was this that excited in him the dread lest he should be incompetent to discharge adequately the duties which would fall upon him. There was nothing of malingering or shirking in his case. There was no fear of physical injuries or of returning to the front; on the contrary, he was anxious to go back. His fear lest the possibility of his failure would be bad for his platoon was wholly due to that admirable sentiment of regimental loyalty, which comes out so strikingly in the nervous troubles of the non-commissioned officer.

This class of case demands a great deal of patient and sympathetic attention before the real cause of the trouble is elicited, and then months of re-education may be required to build up anew the man’s confidence in himself.

The second case is that of a soldier who had suffered from severe shock symptoms and had recovered. In conversation with the medical officer the soldier expressed his willingness, and even his desire, to return to the front, in full knowledge of the fact that the officer’s report in that sense would lead to his being sent back to fight. That night the patient was awakened by a terrifying dream, the true significance of which was certainly not adequately appreciated by him. Although he dreamt that he was afraid to go back to the front, apparently he did not realise that he was actually afraid—_i.e._, that the dream had any meaning. On examination it proved to be a detailed forecast of the imaginary incidents of his return to his regiment, and of his attempt to commit suicide when ordered to go to France. Here was a man who of his own initiative had asked his doctor to certify him as ready to go back, yet in his sleep the train of thought, started by the discussion of the possibility of his return, working subconsciously, had stirred up images of what this implied, and reinstated emotions of so terrifying a nature that in his dream he preferred suicide to facing the ordeal again.

It may perhaps be allowable to quote in this connection the view of a German neurologist, Prof. Gaupp, on the “shock-cases” which have been sent back from the German front.[21] At the same time it is important to remind our readers that Gaupp is writing of a conscript army, the authorities in which are certainly not notorious for lenity to the individual; further, that up to the time of writing the present chapter, all the “shock” patients in Great Britain have been men who voluntarily elected to serve their country, the majority of them having enlisted in the earliest stages of the war.

In discussing cases where nervous trouble, uncontrollable in nature and intensity, had led to the patients being kept in German hospitals for months, it was sometimes found that the mental foundation which was a causal factor of these troubles was a more or less conscious anxiety concerning the possibility of a return to the front.

“There is no justification,” says Gaupp, “for calling every instance of this a case of malingering or simulation. There are quite capable men of irreproachable character whose nervous system is positively unfitted for the hardships and horrors of war. They have enthusiasm and the best of intentions but these cease to inspire them when the horrors and terrors come. Their inner strength

rapidly decreases, and it only requires an acute storm to break upon the nervous system (such as the explosion of a shell or the death of comrades) for their self-control to vanish completely. Then automatically their condition changes into what is popularly called ‘hysteria.’ The exhausted mind then feels that it is no longer master of the situation, and therefore ‘takes refuge in disease.’ At first, as a rule, obvious signs of terror and anxiety (trembling, twitching, etc.) manifest themselves; if these are cured there still remain chronic symptoms of hypochondria and despondency. Time, however, has its effect in many of these cases.”[22]

If a patient comes into the hands of a physician before the processes of rationalisation and systematisation have become established, the medical officer should be able to meet his difficulties, and help him correctly to interpret his unusual experiences by explaining to him their origin and nature.

“The application of discreet sympathy and tact by a physician who endeavours to discover something of the man’s past mental history may be able to reassure a patient upon his particular trouble with the happiest of results. To a man quite unacquainted with text-books or speculation on psychology there can be no darker mystery than the working of other people’s minds. To such a man the natural conclusion is that his own mental processes are universal and normal. But if, as a result of some nerve-shattering experience of warfare his mind suddenly develops a trick which was quite unknown to him before, though this development may be far from abnormal, to the troubled patient it may seem to be an unquestionable symptom of madness.”[23]

Many of the cases in which a patient has merely needed reassuring have been of this type. A short and very simple explanation of some elementary facts of psychology is often sufficient to bring about an immense change in the man’s condition, which has led to his curing himself. And this is the ideal method of cure.

It may seem that an inordinate amount of space has been devoted to the demonstration of a simple truth, that mental, like bodily disorder, should be treated early, or complications may ensue. But there are reasons for giving so much prominence to this aspect of the subject. The chief is that in our own country, mental disorder is seldom treated in its early stages. Nearly all our elaborate public machinery for dealing with this distressing form of illness is devised, and in practice is available, only for the advanced cases. This war has shown clearly a truth which, of course, was already known before to many doctors, but never adequately appreciated by the general public, that a case of advanced mental disorder may pass not only through various milder stages on its way, but that if intercepted at these earlier stages, it may frequently be cured with ease.

Another point which should be emphasised is this: shell-shock involves no _new_ symptoms or disorders. Every one was known beforehand in civil life. If by any stretch of the imagination we could speak of a specific variety of disease called shell-shock, it would be new only in its unusually great number of ingredients. And the most gratifying truth of all is that even this hydra-headed monster, if caught young, can be destroyed.

From the fact that shell-shock includes no new disorders the important inference may be drawn that the medical lessons taught by the war must not be forgotten when peace comes. The civilian should be offered the facilities for cure which have proved such a blessing to the war-stricken soldier.

CHAPTER II.

Treatment.

In discussing the question of treatment we do not propose to deal with general therapeutic measures which every physician in charge of nervous or mental patients is hardly likely to neglect.[24] The importance of a generous and easily digested dietary is generally recognised: as also is the need for quiet and congenial surroundings, and for shielding patients from disturbances, such as noises and the sight of wounded, which are likely to evoke painful emotions and vivid memories of their experiences at the front. It is also obviously important that the physician should deal promptly and discreetly with any bodily ailments from which the patient is suffering, being careful neither to minimise their gravity and so give him any reason for the grievance that he is not receiving proper attention, nor by exaggerating them to add this anxiety to his other troubles.[25] These are questions which may confidently

be left to the discretion of the physician in charge.

Firmness and Sympathy.

But there are certain other therapeutic measures commonly recommended in text-books for application in the cases of patients suffering from neurasthenic and hysterical troubles, which cannot be thus summarily dismissed. As many of these patients are irritable and childishly peevish, it is necessary that they should be treated with sympathetic firmness, tact and insight. But, unfortunately, the words “firmness” and “sympathy” are interpreted in a great variety of ways. While it is important, for purely therapeutic reasons, that discipline should be maintained, and that when the physician has decided what he considers the proper treatment for the patient this should be rigorously carried out, it is manifestly disturbing and injurious in many cases for the officer to insist upon all the exacting details of military rules and regulations. For the mentally healthy soldier, obedience to stern and even harshly rigid regulations is often vitally important; but an attempt by a medical officer to treat a ward of neurasthenic patients in this way usually has disastrous results.

Quite apart, however, from the military aspects of the case, the physician, without really investigating the history of a patient, may label his trouble “hysteria” and forthwith adopt a course of “firmness.” He may assume the attitude of doubting the genuineness of symptoms which are very real to the sufferer. Under the plea of helping to cure the patient the officer may assure him that there is nothing much the matter with him and that if he tries he will soon be all right. Such advice may be justifiable if based on a real insight into the state of the individual sufferer, but this knowledge can be gained only by a patient investigation of the cause of his trouble. If the advice is given without this insight, it is a mere shot in the dark. The fact that the device succeeds in a certain number of cases is no excuse for its general adoption. And when it “misfires” no one realises the fact more quickly than the patient himself. He realises that the officer does not appreciate his condition and his confidence is thereby destroyed.

It is useful, too, to consider for a moment the nature of treatment by “sympathy.” When we used the phrase “sympathetic firmness” we intended to indicate the insistence upon a strict observance of such methods of treatment as a real insight into the patient’s condition may suggest. The word “sympathy” was used in its literal sense of “feeling with” the sufferer. But there is no class of patients upon whom sympathy of the injudicious kind is more prone to work serious harm than the psychoneurotic. The knowledge of this fact is often the excuse for the adoption of the opposite attitude and the prescription of “firmness” which, as we have seen, may be equally unintelligent and injudicious.

But sympathy of the injudicious kind is not _real_ sympathy. For unless the sympathiser has a true appreciation of the patient’s condition, and can look at things from his point of view, he cannot really feel _with_ the sufferer. The latter may arouse in the would-be sympathiser tender emotions and sympathetic “pain,” but unless the sympathiser have insight, the pain, to put it crudely, is not likely to be “in the same place” as that of the patient. Such misplaced emotion and false sympathy, whether on the part of the doctor, the nurse, or the patient’s relations, may do much harm.

In mild cases of mental trouble, however, where the patient still retains a goodly portion of self-confidence and self-respect, this “petting” variety of sympathy may sometimes be effective. Such a patient may be cheered up by the presence of people sufficiently interested in him to be sorry for his condition; and it may help him to look on the brighter side of things and to forget his worries and anxieties. But often it is apt, by suggestion, to aggravate his troubles or even to discourage him from trying to recover.[26] Perhaps it would be more accurate to say that such treatment gives him no inducement to get better.

There are still not a few physicians who regard the group of functional troubles commonly labelled “hysteria” as something closely akin to malingering. If it would not be considered invidious we could quote the opinions of well-known physicians published within the last five years, suggesting that there is no real line of demarcation. (It is not uncommon to meet the expression “_detecting_,” instead of _diagnosing_ hysteria.)

But even among those who regard these serious affections as something more than mere simulation there is a tendency to look upon any form of sympathy as a dangerous pandering to the patient’s lack of will power.[27]

This attitude often finds expression in leaving the patient alone to get better by his own efforts, or in suggesting to him that he is not so ill as he thinks he is, and that all he needs is some work to occupy his attention.

The attempt is often made to justify such methods by the plea that it is “bad for the patient to talk to him of his worries.” But how a physician is to rid a patient of the very root of all his trouble without first discovering and then discussing it with him is not apparent. Nor, again, is it any more rational merely to tell a man who is weighed down with some very real anxiety to “cheer up,” or to “work in

the garden," or "take a walking tour."

We are not maintaining that such methods do not often meet with success in the case of many patients who are only mildly affected and earnestly want to get better. But experience shows that such advice is often fraught with danger, and, in severe cases of mental affection is worse than useless. The experience of those physicians who have been treating such patients with sympathetic insight during the last two years affords a striking condemnation of the theory that it is generally "bad to talk to them of their worries." It has repeatedly happened that as soon as the patient was asked about his troubles he made a full statement of all that was troubling him and was obviously relieved to confess his worries to someone who took an intelligent interest in his welfare.

In many cases the mere unburdening of this weight of anxiety and the removal by the physician of quite trivial misunderstandings which were the original causes of it, were sufficient to cheer up the patient and to start him on the way to complete recovery. Yet many of these men had been inmates of a series of hospitals in which no attempt had been made to discover what was the real source of all the trouble. Thus to their other worries and anxieties was added the real additional grievance that they were being neglected and were of no account. In many cases this constituted a serious aggravation of the patient's mental disturbance and encouraged him to believe that his state was already beyond help.

Those physicians who look upon such milder psychoses as varieties of simulation should be reminded that the methods we have just mentioned are not often likely to be effective in cases of real malingering.

In discussing the therapeutic use of "firmness" we have not thought it necessary to mention those applications of this method which at times are practised by combatant officers at the front. The use of military authority to suppress the minor manifestations of nervousness, or the resort to such expedients as unexpectedly firing off a gun alongside a man afflicted with functional deafness, are merely examples of the application of "suggestion." They are akin to the use of "firmness" by the physician who has not investigated the cause of the patient's trouble. The results of such expedients are as erratic in the one case as in the other. But there is no need for us to discuss this practice further, except to add that the knowledge that such "treatment by military authority" has been tried before, still further diminishes the justification for resorting to such measures when the patient reaches the home hospital.

Isolation. Many physicians regard isolation as an appropriate method of treatment for soldiers suffering from shock, and they urge in justification of such a procedure the success which often attends its use in civil cases. We do not deny the utility of isolation for suitable cases, and success has attended its use when the patient's condition obviously required it. But the circumstances which were responsible for causing the mental disturbance in the soldier may be of a totally different nature from those which have upset the civilian; and therapeutic measures which may be appropriate in eliminating the civilian's sources of irritation might be wholly unsuitable, if not positively harmful, in the case of soldiers.

It cannot be too strongly emphasised in connection with this subject that most of the theory and practice of treating hysteria by isolation has been developed in civil life, and in very many cases with reference to well-to-do women living in the lap of luxury. When such persons develop hysterical symptoms, some sources of irritation in the home or the social environment are often responsible. By isolation the patient is removed from the noxious influence of both domestic worries and mistaken sympathy; his or her whims and fancies are compulsorily subordinated by self-discipline and consideration for others. At home it is impossible satisfactorily to enforce such measures and the attempt to do so will almost inevitably fail, because sympathy, curiosity and anxiety on the part of various relatives hinder the attainment of these objects. By isolation the patient is removed from these unfavourable psychical influences. Through the freedom from such disturbing stimuli, the abnormally intense reaction of the mind is reduced. And in many patients of this class the desire to be cured or to be active, which is produced by the boredom of isolation, works favourably.[28]

But in most soldiers the circumstances are altogether different. In the first place, the patient secures the change of surroundings by his removal from the trenches to the hospital. Isolation, therefore, can hardly be justified on that score. At the same time, the removal to a military hospital at any rate should obviate all danger of his being pestered by foolish relatives and friends with their mistaken sympathy or excessive attention. And as regards the importance of discipline and routine, the soldier is in a position very different from that of the wealthy society lady, for he has already been subjected to such training.

In some instances, however, just as in the civil cases, the boredom of isolation may produce the good effects noted above. But there is the corresponding disadvantage that if you isolate a man and put a special nurse to look after him it is impossible to convince him that his case is not serious. It may, indeed, help him to persuade himself that he is really going insane. As a matter of

experience, it is found that very many men cannot stand isolation for long; they feel that they must break out, even if they realise that punishment is certain for doing so. The conversation of patients who are undergoing treatment by isolation is often perfectly frank about it. They tell the medical officer they will break out at the first opportunity; that the few hours of freedom would more than compensate for the punishment which would come afterwards. Again, it must be apparent that, when the trouble is due in any considerable measure to the re-awakening of emotions linked up with some painful earlier experience, isolation is not likely to be effective in many cases, and may be definitely harmful. Neither should it be forgotten that such measures fail to isolate the patient from his worst enemy, himself.

Even in those cases in which it is useful, isolation, if unduly prolonged, may spoil its own good effects. It may so accustom the patient to a solitary mode of existence that the presence of other persons may make him irritable when at the end of his time of seclusion he is compelled to associate with his fellows.

There is another fact which has to be taken into consideration—and this applies especially in civil practice, where the patient or his family have to pay for the treatment. We refer to the expensiveness of treatment by isolation. Unless it can be shown that it is the best or the only hopeful method to adopt, the physician must feel some hesitancy in the majority of cases, in prescribing such costly measures.[29]

Déjerine and Gauckler[30] have given an admirable account of the use of isolation in the treatment of neurasthenia and hysteria. They are careful to point out, however, that even in the case of civilian patients, with whom of course their treatise is concerned, “isolation, even accompanied by rest and overfeeding, is never enough.” It is merely an adjunct, though, under certain circumstances, a necessary one, of the treatment by persuasion. But “it would be irrational to look upon the isolation of neuropaths as a therapeutic necessity from which one might never depart. It only applies to particular cases.” In proceeding to define the class of civilian patients for whom such methods are appropriate they emphasise the value of isolation for those whose troubles are due to, or aggravated by, “a bad family environment.” In most cases the circumstances of the war-stricken soldier do not come within the categories which they suggest as justifying isolation. Moreover, most of the benefits which they attribute to this therapeutic measure, _i.e._, removal from home surroundings and from the particular worries and anxieties which have caused the mischief, are attained (as we have already pointed out) when the soldier is an inmate of a special—or, in fact, of any—hospital.

When Déjerine and Gauckler proceed to define the different degrees in which the method of isolation may be practised; _viz._: (1) strict isolation; (2) absolute isolation from one’s family circle and environment, and (3) isolation from one’s family circle alone, or from one’s usual environment alone—it becomes clear that the treatment of every soldier who enters any hospital inevitably comes within the scope of categories 2 and 3.

Even when writing of hysterical women these French physicians tell us that—

“to show how slightly (their) experience has inclined (them) towards any systematic treatment of the psychoneuroses by isolation,” isolation has not seemed (to the doctors) to be necessary for “at least a third of the neuropathic women who have been cared for at the Salpêtrière. Again, it must be added that, of the patients admitted, a certain number have been received at the hospital and naturally submitted to the discipline which belongs to an isolation ward much more for humanitarian and social reasons than because absolute isolation seemed to be formally indicated.”[31]

From the completely different nature of the circumstances of the nerve-stricken soldier and civilian respectively it is clear that such total isolation can be considered necessary for soldiers only in very few cases, even though the modified forms of isolation, to which reference has been made, may be useful for most of such patients. The important point that emerges from this discussion is the necessity which is laid upon the physician of determining, in the case of each individual patient, whether isolation of any kind is desirable, what form it should take, and especially when it should be used, modified or discontinued.

Suggestion and Hypnosis. We have already touched briefly on the need for sympathetic firmness and for inspiring the patient with confidence that he will recover. But such firmness can be useful only when it is supported by respect for and confidence in the physician. In most cases such respect can be gained only by acquiring a real insight into the patient’s condition and by treating him tactfully and reasonably. It is too often forgotten that the neurasthenic patient’s continual and intense criticism of himself makes him especially quick at intuitively becoming conscious of the physician’s failings. Under such circumstances, if the doctor does not secure the patient’s respect and convince him that he really understands his condition, the former’s firmness and confident assurances will avail him nothing: he has shown his hand; his failure will excite contempt; and the patient’s intractable, _enlightened_ stubbornness will be fatal to any further hope of influence on the part of that particular physician.

Ever since mankind first sought help from his fellows for his afflictions of body or mind, confidence in the efficiency of the adviser's ability has been an essential factor in leech-craft. To be able to convince a patient that he is going to recover and that medical advice will help towards that end is certainly not the least of the physician's qualifications. But unless the assurances given him are based upon real insight and understanding, the process of securing the patient's confidence is not very different from the charlatan's blatant boasting. In other words, it is analogous to the confidence trick.

The confidence which is inspired in the patient by his conviction of the physician's real understanding of his condition is an altogether different matter. Such "suggestion" necessarily enters into all successful treatment and this applies in a very special manner to the cure of mental ailments.

But the question arises, is it useful or desirable to supplement these measures of suggestion which are incidental to all human intercourse, by more positive measures of induced "suggestion" or hypnotism? There are wide discrepancies of opinion with regard to this matter. And, in endeavouring to come to a conclusion concerning it, it is important to eliminate as far as possible the emotional tone which the warm discussion of this question has aroused in the past.

The positive usefulness of hypnosis in relieving many of the acute symptoms in recent cases of shell-shock has been fully demonstrated by the important series of articles by C. S. Myers, in the _Lancet_.[32] When it is possible by such means to restore to the patient his lost memory or speech or banish his despondency it often proves that the only hindrance to the complete restoration of his normal personality has been removed.

"It may be argued," to quote Myers's own account, "that mutism, rhythmical spasms, anæsthesia, and similar purely functional disturbances disappear after a time without specific treatment. But no one who has witnessed the unfeigned delight with which these patients, on waking from hypnosis, hail their recovery from such disorders can have any hesitation as to the impetus thus given towards a final cure. More especially is this the case in regard to the restoration of lost memories. Enough has already been said here about the striking changes in temperament, thought, and behaviour which follow on recovery from the amnesia... The restoration to the normal self of the memories of scenes at one time dominant, now inhibited, and later tending to find occasional relief in abnormal states of consciousness or in disguised modes of expression—such restoration of past emotional scenes constitutes a first step towards obtaining that volitional control over them which the individual must finally acquire if he is to be healed.

Thus the minimal value that can be claimed for hypnosis in the treatment of shock cases consists in the preparation and facilitation of the path towards a complete recovery."[33]

Even if we admit that other measures, such as the administration of chloroform for the cure of hysterical mutism, may in some cases effect similar improvements, this should not blind us to the incontrovertible fact that hypnotism has been proved to be a valuable therapeutic agent in the early stages of shell-shock.

As a cure for certain patients who have passed the acute stages of shell-shock or other forms of war-strain, its use requires great discrimination in the selection of suitable cases and extreme care in its practice. It is very probable, too, that hypnotic suggestion by itself should never be regarded as sufficient treatment for these cases, though undoubtedly it may be of great use as a part of such treatment.

A view endorsed by some well-known physicians is that all psychotherapy should be addressed to the functions of consciousness, and that hypnosis, which is addressed to the functions of automatism, is therefore undesirable. As a general statement this is undoubtedly true of a great number of cases, but there occur instances in which it seems that this sensible rule may be wisely and judiciously broken. In some cases hypnosis helps in more quickly breaking down resistances, which occur in patients too beset by their own auto-suggestion and false beliefs to be able easily to grasp the arguments and persuasions which the physician may have spent days and weeks in vainly endeavouring to get accepted. Thus assistance may be sought without in any way interfering with subsequent treatment of the patient by psychological analysis and re-education.

The following instance illustrates the use of hypnotic suggestion in the manner described above.

The case was one of violent spasmodic tremor in the right arm of a soldier. When in a state of convalescence from a wound and shell-shock he suddenly encountered his company officer, to whom he was greatly attached. This officer had lost his right arm since he was last seen in France by the patient. The shock of suddenly meeting the officer in this condition set up the man's tremor. The case came under psychotherapeutic treatment some weeks later, when the patient, who was an extremely emotional

individual, had lost all hope of recovery. Any attempt at purposive movements of the right hand and arm threw all the muscles of the right side of the body into a violent state of jerky tremor.

Long continued treatment by persuasion failed to effect any improvement whatsoever. The medical officer in charge of the case therefore decided to try hypnotic suggestion. This was easily carried out; the hypnotic state being moderately deep, though the patient was still in touch with his environment. Hope, courage and assurance of recovery _following his own effort_, together with determination to make every endeavour, were suggested to him. The patient was assured at each sitting that his nerves and muscles would every day respond more and more to his efforts at self-control. After a very few short sittings the man's hopeless attitude became changed to one of hope, effort and attention in the waking stage, and there was a slight but decided improvement in his voluntary power. Hypnotic suggestion was then given up, and the treatment was continued by means of encouragement, exercises and explanation of his trouble, with the result that two months later he was fit for discharge from the hospital.

It may reasonably be doubted whether methods of persuasion alone would have cured this man. In any case, it is clear that it would have taken a very long time. It is also probable that hypnotic suggestion alone, if continued, would very quickly have removed the symptoms. It may be doubted, however, whether it would have effected a permanent cure in a person so open to auto-suggestion. It seems, therefore, that a judicious combination of methods was advisable.

We are of the opinion that hypnotic treatment, when used with skill, discretion, and discrimination, has its place in the treatment of shell-shock and similar conditions, both in the acute and chronic stages.

In the majority of cases of some considerable duration, however, and in practically all those in which the trouble is due to some ante-war worry or emotion, it may be regarded as provable that hypnosis _alone_ will be of relatively slight use and in many cases may be positively harmful, for under such circumstances, even with the most favourable conditions, it would result merely in the removal of symptoms; and the removal of one may be followed by the appearance of another, which may even be induced by the process of hypnosis. Moreover, in cases where there is a tendency to the development of a double personality hypnosis may have the effect of increasing the risk. Further, if the patient has sufficient of his own will-power to enable the process of re-education to be carried out, it is clearly undesirable, both on psychological and ethical grounds, for the doctor to impress his influence from without.

In considering the possibility of the usefulness of hypnotic suggestion it is important to bear in mind that various factors may come into play in impressing an event upon the patient's memory, or in determining the effect of the shock from which he is suffering when he arrives in hospital. In the first place there is the vividness or intensity of the stimulus; in the second, the degree of recency; in the third, the frequency of the stimulus; and in the fourth its relevancy. By the latter is meant the extent to which a given event appeals to the individual's past experience, and becomes integrated into his personality.

A patient who has recently received a severe shock, the effects of which alone represent the real trouble, without the disturbance of any antecedent experience, might quite well be relieved by hypnotic suggestion from sleeplessness, pain, or amnesia; and in some cases this removal of the acute symptoms which determine the persistence of the shock effects may lead to complete recovery. A single and sudden wholly irrelevant experience, such as the bursting of a shell, which has no relationship whatever to the patient's past experience, and produces effects by its vividness and its recency, might quite well be neutralised by another kind of wholly irrelevant intrusion, such as hypnotic suggestion. This argument may perhaps be made more intelligible by a homely analogy. A temperate man walking along the street might be thrown temporarily into a condition of faintness or collapse by seeing some ghastly accident, but by taking a "brandy and soda," which to such a man would be a wholly irrelevant experience, the physiological expressions of his emotions might be controlled and he might be able to proceed on his way, and to overcome completely the effects of the transitory occurrence. But in the case of a man who, for example, had been greatly worried by monetary troubles for a number of years, the "brandy and soda" would not produce anything more than a temporary alleviation of his troubles. The latter illustration represents the chronic psychosis which, as Déjerine has so admirably explained, is quite unsuitable for hypnotic treatment. But the distinguished French neurologist's statements do not seem to apply to the former type of case, due to a vivid recent shock, in the symptomatology of which troubles before the shock play no part. In such cases the results of hypnotic suggestion are often brilliant, if erratic, as is the "brandy and soda cure" for the man who is overcome by a sudden terrible experience in the street.

There are, however, patients who have not sufficient will-power or intelligence to be properly re-educated, to whom a certain amount of suggestion may be of some use.

Those who have used hypnosis in civil practice are aware that in certain individual cases of long-standing trouble, such, for example, as chronic alcoholism, hypnotic treatment is of unquestionable value. Among soldiers suffering from the long-standing effects of shell-shock, hypnosis may be able in some cases to help in the restoration of health with an effectiveness that no other method can rival.

Both the danger and the possible usefulness of hypnotism may be illustrated by an actual case. It is that of a man all of whose companions were destroyed by the bursting of a shell, and who suffered for months afterwards from complete loss of memory. A medical man hypnotised him, and perhaps with undue tactlessness, brought back the memory of the critical incident at the front, stripped of all the episodes which led up to or followed it. This excited in him the most violent emotions, and he became sick with terror; for the revived incident seemed perfectly real to him, or, as he described it afterwards, “it jumped up against him,” and for weeks he was so utterly terrified that he would not go near the doctor. Even though he could not retain the memory of any other recent events the horror of that experience seemed to have made him remember his dread of a particular medical man. But by making use of the information gained during that revival under hypnosis of an incident unknown to anyone but the patient, which his amnesia up till then had kept sealed up, it became possible for another medical officer to bridge the gap between his memory of previous events and the experiences which the patient was known to have had in the military hospitals.

In speaking of the results of hypnotic treatment as being brilliant but erratic, it is important to remember that the same observations apply to suggestion without hypnosis. For instance, the application of electricity to the vocal cords in cases of hysterical aphonia affords an admirable illustration of the treatment by suggestion, even if the method savours of charlatanism. An excellent demonstration of the part which psychical factors play in such cases is afforded by the story of a sailor on the German battle-cruiser _Derfflinger_, recorded by Blässig.[34]

“A seaman from the _Derfflinger_ was brought into a naval hospital with loss of voice on Dec. 22nd, 1914, and could speak only in a whisper. He said that he had always had good health, with the exception that as a child he had diphtheria, but recovered without tracheotomy or any complication. His voice had always been clear and well under control. At the beginning of December he had a slight cold, which he attributed to sentry duty on deck in very stormy and wet weather. While in the ammunition chamber of the big guns he was greatly upset during the firing and suddenly lost his voice. After fourteen days he recovered his speech. On Feb. 12th, 1915, he returned to hospital with complete loss of voice, immediately after the naval engagement in the North Sea. On Feb. 15th he was treated with electricity, directly applied to the vocal cords, and on March 20th he was discharged with complete recovery of his speech. But on returning to duty, as soon as he went on board his ship his voice was suddenly lost for the third time, and he remained aphonic.”

This is clear evidence of the fact that his trauma was psychical. His previous history perhaps contains the clue explaining why, in his case, it was his voice which was affected. The application of the faradic current was suggestion pure and simple.

In emphasising the limited usefulness and possible danger of suggestive therapeutics in many cases that are not quite recent, we have not been referring to that method of suggestion which is involved to a greater or less degree in all successful treatment of disease—the process of gaining the patient’s confidence and impressing him with the idea that he is going to recover.

“The conversational attitude, the familiar manner of talking things over, the heart-to-heart discussion, where the physician must exert his good sense and feeling, and the patient be willing to be confidential” is the method which Déjerine calls ‘psychotherapy by _persuasion_.’ “It consists in explaining to the patient the true reasons for his condition, and [for] the different functional manifestations which he presents, and above all, in establishing the patient’s confidence in himself and awakening the different elements of his personality, so as to make them capable of becoming the starting-point of the effort which will enable him to regain his self-control. The exact comprehension of the phenomena which he presents must be gained by the patient by means of his own reasoning.... The part that the physician plays is simply to recall, awaken, and direct....”[35]

No one who has not had the experience of guiding mental patients in the way so lucidly expounded by the French physicians can form any adequate conception of the remarkable efficacy of these common-sense methods in restoring to those who are afflicted a normal attitude of mind. It is certainly saving considerable numbers of soldiers from the fate of insanity. These methods are not novel, even if the fuller comprehension of their mode of operation is only dawning upon us now. This point has been admirably expounded by Déjerine and Gauckler, from whose book we must quote once more:—

“May we be permitted to quote a few lines in which Bernardin de St. Pierre has defined, more exactly and better perhaps than we could do, and with a sort of prescience of what is needed, the very rôle that we would like to [see our physicians adopt towards their

patients].

I wish that there might be formed in large cities an establishment, somewhat resembling those which charitable physicians and wise jurists have formed in Paris, to remedy the evils both of the body and of one's fortunes; I mean councils for consolation, where an unfortunate, sure of his secret being kept and even of his incognito, might bring up the subject of his troubles. We have, it is true, confessors and preachers to whom the sublime function of offering consolation to the unfortunate seems to be reserved. But the confessors are not always at the disposition of their penitents. As for the preachers, their sermons serve more as nourishment for souls than as a remedy, for they do not preach against boredom, or unhappiness, or scruples, or melancholy, or vexation, or ever so many other evils which affect the soul. It is not easy to find in a timid and depressed personality the exact point about which he is grieving, and to pour balm into his wounds with the hand of the Samaritan. It is an art known only to sensitive and sympathetic souls.

Oh! if only men who knew the science of grief could give unfortunate people the benefit of their experience and sympathy, many miserable souls would come to seek from them the consolation which they cannot get from preachers or all the books of philosophy in the world. Often, to comfort the troubles of men, all that is necessary is to find out from what they are suffering (_Etude de la Nature_, 1784)."

Déjerine and Gauckler add:—

"One could not express any better, or any more directly, what we never cease to maintain, however lacking in science it may seem at the first—namely, the real therapeutic action of kindness.

Liberated morally, and having regained consciousness of self, and freed in addition from his functional manifestations by the appropriate processes ... the patient is cured. He is cured from his actual attack. But his mental foundation, his psychological constitution, still remains in the same condition which permitted him under emotional influences to become a neurasthenic. The rôle of the physician is, therefore, not ended. He must still build up his patient's life, still practise prophylaxis, and get the patient into a condition where his character will be established."[36]

Rational Treatment. So far in this chapter we have been discussing what may be described as general methods of treatment, which do not _necessarily_ involve any attempt to probe into distinctive individual symptoms and to discover the real fundamental cause or causes of the trouble. The measures so far considered are empirical rather than rational. But they are the only methods of treatment discussed in most of the text-books.

It is an axiom in medicine that correct diagnosis is the indispensable preliminary to the rational and intelligent treatment of disease. This fundamental principle is universally recognised in dealing with bodily affections; but it is the primary object of this book to insist that _it is equally necessary to observe the same principle in the case of mental illness_.

It may seem ironical to stress this elementary consideration, but it is notorious that accurate diagnosis is too often ignored in cases of incipient mental disturbance. It is idle to pretend that such a procedure is unnecessary, or to urge in extenuation of the failure to search for causes that many patients recover under the influence of nothing more than rest, quiet, and ample diet.

Many mild cases of illness, whether bodily or mental, may and do recover even if undiagnosed or untreated. But on the other hand many mild cases get worse; and it is the primary duty of the physician correctly to diagnose the nature of the trouble and to give a prognosis—to decide whether the illness is mild or severe. Some of the most serious cases of incipient mental trouble are those of patients who do not seem to be really ill, and are easily overlooked by a visiting physician. They are quiet and inoffensive and display no obvious signs of the insidious processes that are at work in them. But all the time they may be, and often are, brooding over some grievance or moral conflict, worrying about their feelings, misinterpreting them and gradually systematising these misunderstandings until they become set as definite delusions or hallucinations. If, acting on the belief that it is bad to talk about a patient's worries, the physician leaves such a man alone, he is clearly neglecting his obvious duty. For the whole trouble may be due to some trivial misunderstanding which he could easily correct.

In the severer forms of mental disease, precise diagnosis is even more intimately related to treatment than in the case of bodily illness. For when a patient's illness is recognised as some bodily affliction, such as pneumonia or appendicitis, certain general lines of treatment are laid down as soon as the appropriate label has been found for the complaint, though, in the case of the latter illness, there is added the further problem of whether or not surgical interference is indicated.

In cases of mental disturbance, however, the general lines of treatment cannot thus arbitrarily be determined merely by finding an appropriate label. It is true that as in the treatment of bodily disease, certain general principles must be observed, such as the provision of abundant and suitable food, and the protection of the patient from all disturbing influences. But the essence of the mentally afflicted patient's trouble is some particular form of anxiety or worry which is _individual and personal_. The aim of the diagnosis, therefore, should be not merely to determine the appropriate generic label for the affliction, but rather to discover the particular circumstances which have given rise to the present state. The special object of the physician should be to remove or nullify the exciting cause of the disturbance; and in order to do this it is essential that he should discover the precise nature of the trouble. The diagnosis, therefore, must be of a different nature from that demanded in case of physical illness, where the condition may be adequately defined by some such generic term as "lobar pneumonia" or "acute appendicitis," and its gravity estimated by the general condition and physique of the patient. In the case of mental trouble, the physician has to make an individual diagnosis, based not only upon an insight into the personality but also into the particular anxieties of each patient.

But even when it is recognised that exact diagnosis of the particular circumstances of each individual patient is essential, if the trouble is to be treated rationally and with insight, there still remain many difficult problems as to procedure.

Amongst those whom experience has convinced of the efficacy of psychological treatment for this class of case, there are indications of a divergence of opinion in the matter of procedure. Some believe that it is sufficient if the medical man has discovered the real cause of the trouble and explained it to the patient. Other workers look upon a preliminary psychical examination merely as a means of diagnosis, the unveiling of the hidden cause of the trouble; and consider that the treatment should be the laborious and often lengthy process of re-educating the patient, and so restoring to him the proper control of himself. It is of the utmost importance to emphasise the undoubted fact that those who maintain either of these views to the exclusion of the other are committing a grievous and dangerous error, for there is no sharp line of demarcation between the two procedures.

A sensible and intelligent man, once the cause of his trouble has been made clear to him, may be competent to continue to cure himself, or, in other words, to re-educate himself, and completely to conquer the cause of his undoing. But the duller and stupider man may need a daily demonstration and renewal of confidence before he begins to make any progress. It is precisely analogous to the experience of every teacher of a class of students; the brilliant man will seize hold of a principle at once and learn to apply it without further help, whereas the dull man needs repeated and concrete demonstrations before it sinks into his understanding.

In dealing with soldiers, and this applies with especial force to the regular army, the conditions in many of the cases differ considerably from those of the civilians. Trifling forgetfulness in the civilian would perhaps not be a serious cause of worry, but in the soldier, inured by years of training to strict discipline, forgetfulness of even trivial instructions, or any difficulty in understanding complex orders, is likely to bring down upon his head condign punishment. Such lapses are regarded by the soldier as extremely serious offences, because years of training and discipline have inculcated this idea. When as the result of shock such soldiers are afflicted by even slight forgetfulness, they become worried by it much more than would the civilian and exaggerate its importance until it becomes a real terror to them. As the result of their training they may regard such phenomena as altogether abnormal; and by a process of rationalising what to them is a novel experience, they are apt to imagine that they are going mad. Such patients often dream about incidents in their army life when they had been forgetful and got into trouble; they become obsessed with the haunting fear that they are likely to get into perpetual difficulties, are worried by the thought that they are incompetent for the duties to which they have been accustomed, and may imagine themselves debarred from all useful work. However, they are easily reassured when the medical attendant explains to them that in ordinary life civilians are frequently subject to such experiences, and that it is only the special circumstances of army life which make such trivial lapses seem serious to them. Not only is the soldier much more scared by such things than the civilian, but it is also a very remarkable phenomenon, and certainly one which came as a surprise, that the neurasthenia of a soldier is apt to be very much more serious than that of the civilian. For when a really brave man is stricken by fear he is more seriously affected by the terror of an experience which to him not only has a larger element of novelty than in the case of the civilian, but also wounds him more deeply by convincing him that he is lacking in that very quality which is most essential for his professional work.

The Therapeutic Value of Work.

It should be unnecessary to emphasise the desirability of preventing the neurasthenic from dwelling upon his subjective troubles by occupying his mind with other things. This end may often be achieved by the provision of suitable occupation, and where possible, for many obvious reasons, this occupation should take the form of useful work. The worker then feels that he is not a mere burden upon the hospital which is treating him: the institution in its turn benefits materially. But it is necessary to sound a note of warning

against the indiscriminate prescription of work as a panacea. First of all it should be certain that the work is of such a kind as really to interest the patient and to occupy his mind. There are many varieties of work, especially of manual labour, which can be performed mechanically, and do not succeed in distracting the attention from worries and anxieties. But more important even than this is the consideration that there are some mental troubles from which no form of work will distract the patient. Especially is this the case in many of the psychoneuroses caused by the war. The sufferer is often haunted day and night by memories which torture him not merely by their horror but also by another aspect which is even worse: the ever-increasing moral remorse which they induce. A patient may be troubled not only by the terrible nature of the memory but by the recurring thought, “If I had not done” this or that, “it might never have happened.” The reader will easily see how such a thought may arise in the mind, especially of a nerve-stricken officer or “N.C.O.” after weeks of brooding in private upon the memory of a disaster. Now, such self-reproaches are frequently based upon entirely insufficient evidence, and if the medical officer is given the opportunity of calmly discussing their foundations with the patient, the result is often to reassure him and to enable him to view his past in an entirely new light. It is then, and not before then, that he will be able cheerfully to enter upon useful occupation and to benefit by it. To suppose that the mere physical fatigue induced by a day’s hard work will banish all forms of insomnia betrays an ignorance of one of the most important causes of this malady; _viz._, mental conflict. It is well known that bodily fatigue in the case of a mentally excited patient may merely increase his unrest at night. Again, anyone who has had a few months’ experience of receiving the confidence of these nerve-stricken soldiers will know that some of their troubles are so poignant that the attractions of the (apparently) most interesting kinds of occupation leave them cold.

To sum up, the physician may confidently prescribe work when, by investigating the history of any particular case, he has satisfied himself that such occupation will be likely successfully and profitably to distract the patient’s mind from his worries. But the prescription of work for the patient must be regarded as a sequel to, not as a substitute for, the performance of work by the doctor.

FOOTNOTES:

CHAPTER III.

Psychological Analysis and Re-education.

The methods of treatment which have been described in the foregoing pages: sympathy, firmness, isolation, suggestion in its various forms, and hypnosis; while all useful in their proper place, often prove to be of no avail in cases of psychoneurosis. Where the distressing symptoms lie on the surface so that both they and their causes are easily discoverable by the physician—if, indeed, they have not been known from the beginning, to the patient himself—it is sometimes possible to bring about a complete cure without any very penetrating analysis by the doctor of the mental antecedents of the patient's present condition. Thus, for example, a courageous and keen soldier who, suffering from loss of sleep and from the harassing experiences of the battlefield, eventually breaks down, the precipitating cause perhaps being shell-shock, may need little more to set him on his legs than the comfort, assiduous attention, and pleasant distractions of a Red Cross hospital. For the civilian whose chief trouble is the irritability caused by a multiplicity of minor business worries, or family jars, a few days of isolation, giving perhaps, among the other benefits which we have mentioned, the opportunity to think things out, may have excellent results. The beneficent action of hypnosis in removing the acute disturbances caused by shell-shock has already been illustrated. But a large number of cases fall into none of these categories. Sympathy merely annoys them, isolation tortures them, for besides letting them think—usually in a very unwise way—it helps to confirm their impression that they are seriously ill, just because it involves the treatment of them as special cases. Suggestive measures may be to them like water on a duck's back, and hypnosis may prove of no avail. Firmness may have merely the effect of proving to the doctor that there exist patients firmer than himself. But, fortunately, psychical methods are not exhausted. There still remains at least one—that of psychological analysis and re-education.

The employment of psychological analysis in medicine means the resolution of the patient's mental condition into its essential elements, just as by chemical analysis it is possible to determine that water, for example, is composed of certain definite proportions of oxygen and hydrogen combined in a particular way. Re-education is the helping of the patient, by means of the new knowledge gained by analysis, to face life's difficulties anew.

It is sometimes urged that if this be all that is meant by psychological analysis, alienists have been doing this ever since insanity was first treated, nay, further, doctors have been practising it since the time of Hippocrates. It is pointed out that when a patient is first interviewed by the physician, an inquiry is always made into his mental state and behaviour, and into the presence of delusions and hallucinations or other unusual mental phenomena. His relatives are questioned concerning the relation of his recent behaviour to that at the time when he was considered normal. Now the answer to this assertion is that such an investigation is useful, indispensable in fact, but it cannot be called psychological analysis.

The point may become clearer to the untechnical reader if he will imagine for a moment that a carver, skilled in separating the legs and wings from the body of a bird, should claim to be practising anatomy. The anatomist would at once object that while such separation of limbs from trunk is a small detail which sometimes forms part of the anatomist's task, it can scarcely be called more than a preliminary to his study. For first of all, while to a carver a leg is an ultimate unit, to the anatomist it is, for the naked eye, a collection of bones, muscles, tendons, skin, nerves, veins, arteries, nails and the rest, and, seen through the microscope, a tremendous organisation of infinitely more complex structures. Furthermore, it might be pointed out that merely to separate these more minute structures into their constituent parts and to name them, by no means constitutes the whole of the work of the intelligent anatomist. He wishes to study the inter-relations of these parts, the way in which they work together for the common good of the leg. And lastly, the leg must not be studied only in separation from the trunk, for its functions are subordinate to the requirements of the body as a whole.

So, in the same way, to record that a man is suffering from a delusion of persecution or an unreasonable fear of open spaces is merely to "carve up" the condition of his mind. First of all it must be ascertained how far that delusion has interpenetrated with the rest of his mental life; whether, for example, his false belief is restricted to a specific kind of persecution from a particular person, or is a general delusion that everybody and everything in the world is against him. And again, if the delusion is strictly specific, it is important to know whether it has been the cause of secondary false beliefs, produced by rationalisation, to buttress the primary delusion against the inevitable contradiction from facts which it would otherwise suffer.

Further, the nature of the delusion must be analysed. Why is it of this and not of that persecution? Why is this particular person feared or hated? Is it a constant factor in the patient's existence, or does it break out at certain times? If so, the patient's life at these critical periods must be carefully examined. The doctor must discover where the patient was at the time, what he was doing and thinking, who were his companions, and so on.

Next comes the important inquiry into the history of the delusion. And here, just as the anatomist is able nowadays to mobilise for service all his knowledge of comparative anatomy and evolution, so if the physician has really scientific knowledge, not only of the

delusions in other patients, but also of the development of ordinary beliefs in sane people,[37] he will be immensely helped in his search, and may be enabled thereby to make many short cuts to the essential facts. He will endeavour to date the important stages of development of the delusion; to find a time when, so far as the patient knows, his mind was free from it.

Thus we may say that a psychological investigation of a case of mental disorder dissects its normal as well as its abnormal phenomena into their functional elements. Compared with the procedure which merely records such gross units as delusions or hallucinations, it is as anatomy to mere carving, however skilful the latter may be.

But the psychological investigation is not merely comparable to anatomical dissection. We have also compared the mind to a chemical compound, rather than a mechanical mixture. Especially is this true not only of the normal but also of the abnormal mind, when the latter has had time to settle down into its new position of relative equilibrium and integration; when, for example, a delusion has become so fixed that the patient's life is entirely ordered in obedience to it, and he has ceased to have any doubts as to its reality or to struggle against its domination.[38] It is only when the warring elements in the mind are relatively independent, and before they have succeeded in "making terms" with each other, that the mind even remotely resembles a mechanical mixture. It follows, therefore, that psychological analysis of a case of mental disorder is usually comparable to _chemical analysis_ as well as to anatomical dissection.

Now the most striking result of chemical analysis is to show that the appearance and general properties of the elements composing a compound are different from the appearance and properties of the compound itself. This is exactly the case, too, with mental analysis. A mere dissection of an abnormal condition is sometimes sufficient in the milder cases to serve as the basis for curative measures,[39] but in more advanced cases, or those of longer standing, real analysis is necessary in order to get at the unknown factors.

It is just at this point that a number of investigators of mental disorder decline to go any farther on the path of research. Up to this stage, they say, one is relying upon ascertained facts, for one has the warrant of the patient's own memory for the data obtained. Further analysis of a mental phenomenon must inevitably involve appeal to unconscious factors. And, once one has called in the unconscious as a means of explanation, psychology becomes a mere "tumbling ground for whimsies."

Probably there are few people to whom this statement does not appear to express the universal verdict of common sense. That is precisely what it does. But it should be unnecessary to point out that common sense alone is not always the most reliable guide to the discovery of fact. Unaided common sense not only informed men for centuries that the sun moved round the earth, but told them so with such finality and conviction that extraordinarily unpleasant consequences ensued for those who did not believe in such an obvious fact. And the old belief, wholly false as it is, has still to be unlearnt by every child.

In the same way, the 'common sense' point of view which we have described is not flawless. It assumes that a patient is able not only to surmount the great difficulties of translating his experiences and beliefs precisely into words—a difficult task even for the well-educated person—but also to account for and explain them truthfully.

It may, however, be pointed out that, though this last-mentioned misleading assumption is widespread, it is by no means so universal or so tenacious in man as the "belief of his own senses" that the sun goes round the earth. In fact, quite apart from the teachings of modern psychology, we frequently find well-founded suspicions in the lay mind that a man is not always competent to give the basis of and reasons for his mental condition. This view is summed up in the famous advice to the future judge, "Give your decision, it will probably be right. But do not give your reasons, they will almost certainly be wrong."[40]

What ordinary man, unversed in the subtleties of theology or comparative religion, could give to an agnostic a satisfactory account of the reason why—being let us say, a Christian, and a Protestant Christian—he is a Primitive Methodist or an English Presbyterian? Let us complicate the matter further by supposing that this sect to which he now belongs is not that in which he was brought up by his family! Many of the factors which have contributed to his present religious beliefs may have been entirely forgotten now, recallable only with the greatest difficulty[41] and with the help of a second person skilful in such investigation.

We may take as a good example of the historical complexity of significant attitudes and actions in life, the process of falling in love—especially if it is not, or at least seems not to be, love at first sight. It is generally admitted that, in the development of this psychological phenomenon, onlookers see most of the game. In other words, the actions of the two persons who are gradually becoming more and more attracted to each other are partly determined by motives, which, unknown to them, are patent to their observant relations and friends.

Further examples may be given to illustrate this important and oft-disputed point. Let us suppose that a musical critic, after hearing a new symphony by an unconventional composer, immediately writes a lengthy appreciation of the performance. It is clear that nobody would expect him to be able to give, off-hand, an account of his reasons for every sentence of the criticism. But it is obvious that a single phrase in this account may be but the apex of a whole pyramid of memories emanating from the critic's technical training, his attitude towards the new departure, experiences highly coloured with emotion which a few notes of the music may have evoked, and his mental condition at the time he heard the performance. Nobody denies that these may have shaped or even determined his criticism. But who believes either that they were all conscious at the time of writing the article, or that he could resuscitate them without much time and trouble and perhaps the help of a cross-examiner?

Again, there are occasions when society expects that a man shall be unconscious of the reasons for some of his actions. He is expected, for example, to behave politely, attentively and chivalrously to ladies, not because at the moment of taking the outside of the pavement he remembers why he does so, but simply because he has been brought up in this way. And conversely, too conscious politeness in a man arouses in others—and often rightly—the suspicion that it is a recent acquisition.

We see then that it is rare for a man to be able to give a true account, even to himself, of the reasons underlying his important acts and beliefs, when his mental condition is relatively calm and his social relationships are normal. But when a case of mental disorder is in question it becomes quite obvious that the patient is frequently not in a position to give, either to himself or to another, anything like a complete or true enumeration and description of the antecedent experiences which have brought about his present condition.

It therefore becomes necessary to admit that unconscious factors of great importance may play an influential part in the production of mental disorder and that, therefore, some way must be found of tapping these submerged streams.

The most direct way into the complexities of the unconscious mental processes of a person is afforded by a study of his more "unusual" actions and thoughts. For few persons are so completely adapted to their environment or so perfectly balanced that moments never arise in which their mental behaviour is not surprising, either to themselves or to others. And even the Admirable Crichtons of our acquaintance are not entirely immune from errant moments—at least in their sleep. The dream, then, is the chief gate by which we can enter into the knowledge of the unconscious. For in sleep, the relatively considerable control which most of us in waking life possess over the coming and going of mental events is almost if not entirely abrogated. Thoughts and desires, which, if they attempted to dominate consciousness in waking life, would be promptly suppressed, arise, develop and expand to an astounding extent in the dream.

This statement, of course, is entirely independent of the implications of any one "theory of dreams." Its truth is evident to anyone who has honestly recorded or considered his own dreams for even a short period.

Other unusual mental processes are manifested in such events as "slips of the tongue," "slips of the pen," the mislaying of important objects, the forgetting of significant facts, or conversely the inability to get an apparently unimportant memory out of one's mind. All these phenomena, common enough in the normal individual, are usually more frequent in the abnormal mind. Besides the patient's voluntary account of, and comments upon, these events,[42] other methods of obtaining data are possible to the physician. He will note the matters about which in conversation the patient is apt to become silent, embarrassed or inexplicably irritated, to hesitate, to say he has forgotten, or even to lie. All these sidelights upon the mental make-up are carefully noted by the physician and the deductions from them compared, not only with the patient's accounts of himself on different days—narratives which when put together may show important discrepancies and thin places—but also with the information obtainable from his family. These devices serve to bring to light in an extraordinary manner a whole number of memories, many of them of immense significance for the comprehension of the patient's present mental state, which it would be utterly impossible to discover in mere conversation or even by cross-questioning.

It is sometimes felt that these methods which savour strongly of catching the patient tripping, while they may unearth some interesting details of his past life, do no more than exhibit under a strong magnifying glass a few minute excrescences upon his otherwise fair mental countenance. But it should be pointed out that nobody who has ever honestly collected together and compared the memories which have coalesced to compose a dozen of his dreams—especially if he has done so with the help and under the cross-examination of a candid friend who knows him well—will maintain that the material thus found is unimportant. As Professor Freud says, "The dream never occupies itself with trifles." It is probably just because the thoughts and desires underlying the dreams have been refused their normal outlet, that they express themselves in such bizarre forms.

Moreover, the fact should not be overlooked that in other sciences—including the most exact, the physical sciences—the most profoundly important general conclusions are often arrived at by the examination of unusual phenomena, of nature "caught tripping." The study of the thunderstorm was the foundation of our present knowledge of that great force which is active not only in thunderstorms but throughout all matter. Observation of the sporadic and relatively unusual volcanic eruptions of the mind may prove to be an important foundation of our future knowledge of general psychology. As in the inorganic, so in the organic world, there is no sharp line dividing normal from abnormal, and the unusual phenomenon is sometimes simpler and more easily studied than the usual, as "Sherlock Holmes" was so fond of demonstrating.[43] From a scientific standpoint, then, we have every justification for pressing to the utmost our study of the unusual mental phenomena exhibited by the patient, and for our belief that their nature is not unimportant, but highly significant for therapeutical purposes.

Another objection, however, is frequently levelled against such a procedure, from quite a different direction, or rather from a number of directions. This objection can be expressed simply in words, such as "One ought not to probe so deeply into a patient's innermost mental life," and is not to be met by a single argument. The reason is that it is polyhedral in form, and that each of its faces or aspects must be considered separately. For it should be obvious to everyone that such an objection cannot be flippantly waved away.

The aspects of this question which seem to have more particularly appealed to the critics of the method which we are describing, are at least four in number, which we may describe as the æsthetic, social, medical and moral.

The origin of the first, the æsthetic aspect, is easily seen. It is quite clear that in the investigation of the inmost secrets of a person's life (and particularly of a life which has become so entangled and complicated that the help of another is sought for its restoration to 'mental tidiness') there must emerge frequently much that the patient finds unpleasant to relate. When we remember that a neurosis often (perhaps always) occurs as a result of the patient's inability to adjust his instinctive demands to the opportunities of his environment, it becomes clear that in the investigation of his history discussion is inevitable of mental events in which the fundamental instincts have played a great part. Now, of those important instinctive impulses, it is obvious that in a civilised community few are so often thwarted, deliberately repressed, or otherwise obstructed as the powerful one of sex. It therefore follows that in a large number of cases the discussion of sexual matters becomes unavoidable. Some critics have seized on this point as the weak spot against which to launch their attacks, descanting upon the unpleasantness, even the nauseousness, of such discussion. Not all of them, however, make it clear whether in their opinion it is the patient or the doctor who should be shielded from such unpleasant experiences. If the latter, the verdict of society would probably be that the sooner a man requiring such protection was excused not only from these uncongenial duties, but from all medical obligations whatever, the better for the community. If the former, it may be pointed out that every reasonable person will agree that the man who does not tell the whole truth to his doctor or his lawyer is a fool. Furthermore, even under present conditions, if it be considered advisable in the interests of the patient's bodily health, the doctor does not hesitate to ask, and the patient to answer, questions about the most intimate matters, some of them literally and not merely metaphorically nauseous.

We may therefore dismiss the æsthetic objection as unworthy of the consideration either of a conscientious doctor, or of a reasonable patient.

We may turn now to what we have designated the social aspect of the objection. It should need little explanation. There has arisen a convention, subscribed to consciously or unconsciously by many, that the doctor shall ask and the patient answer quite freely questions relating to the patient's bodily well-being, but that any unusual mental occurrences must be considered the patient's private affair into which it is not the business of the doctor to pry.

It would be rash to deny that up to a certain point this convention is susceptible of defence. But, carried too far, it is productive of disastrous results. Moreover, it is impossible for a doctor to treat many varieties even of physical disease without becoming to a great extent the confidant not only of the patient but often of his family. And there is no doubt that the present unwritten law that the doctor should confine himself to the patient's physical ills is often judiciously disobeyed by very many successful practitioners. Yet it must be recognised that the convention exists, and like all social usages is extremely tenacious.

The chief medical objection, which we shall now consider, is usually expressed in some such form as the assertion that "it makes the patient worse to talk about his worries" and that one should rather "try to make him forget them." Let us examine these statements, both of which contain a certain amount of truth, but if applied without qualification to serious cases of incipient mental disorder can by their respective negative and positive tendencies do an incalculable amount of harm. They are often the result of

applying experience acquired by the successful reassuring of a certain type of “malade imaginaire,” to the consideration of far more complicated cases in which such easy and straightforward treatment is impossible. A man, let us say, visits a doctor and confesses to him his fear that he is suffering from some organic disease. The physician after a careful examination proves to the patient by objective means that there is nothing the matter with him; the sufferer is reassured and returns to his daily business and in due course forgets about this worry or ceases to be troubled by the memory of it. Here the diagnosis, treatment, and cure may be uncomplicated and “on the surface.” But even here it should be emphasised that in one sense, far from “making the patient worse” to talk about his trouble, the talking about it was the _sine quâ non_ of cure; otherwise the doctor would never have known of the fear. In another sense, however, talking about the trouble did make the sufferer worse—but for a short time only, during a confession of his apprehensions, or perhaps even for a few days, if more than one visit to the consulting room were necessary before the doctor’s verdict could be obtained.

But not all visits to the doctor end so briefly or so easily as this. The patient’s trouble, on examination, may prove to be organic and of long standing. Does the doctor consider then that it is his duty to emulate the Christian Scientist or to “make the patient forget it?” On the contrary, he does not flinch from the employment of the most searching methods of investigation, lengthy and often painful treatment, and, if it seems necessary in the patient’s interest, he will carry out or arrange for operative interference which may be difficult, expensive, by no means free from danger, and is quite likely to “make the patient worse,” perhaps for a considerable time, before its beneficial results appear.

It is therefore idle to argue that on the one hand psychological methods of treating mental disorder are unnecessary because some patients get better without their application; while, on the other, they are dangerous because they may make a patient worse. The same remarks could be applied to most of the successful operative methods of present-day medicine. All of them are fraught with grave potentiality for harm if applied by unskilled persons.

The degree to which the doctor is medically justified in probing the patient’s intimacies is obviously dependent upon the individual case. Not all patients require such drastic incisions; a fact which has been clearly shown in the special military hospitals. An intelligent man of strong will, whose social relations have hitherto been normal and happy, might be temporarily “bowled over” by the emotional stress of the campaign, but after a few inquiries into the causes of his mental anguish and a few explanations, he is often set on his feet again.

We must not forget, however, the other side of the picture. There are many patients, who, far from being made worse by the confidential recital and discussion of their mental troubles to a suitable person, experience great relief as a result of this unburdening. Men in the military hospitals have expressed this over and over again, in such phrases as, “I have been bursting to tell this to someone who would understand,” or, “I have seen many doctors since I left the front, but you are the first who has asked me anything about my mind.” Frequently the troubles prove to be caused by their ignorance of the great individual differences in minds, so that the appearance in them of a new but by no means pathological mental phenomenon frightens them unduly. We have already referred to cases of this kind in Chapter I.[44] Another frequent cause of the most intense and continuous mental anguish is the exaggerated self-reproach which the patients attach to some real, but in the judgment of others, comparatively trivial defect or delinquency in themselves. To borrow an expressive phrase, the neurasthenic has “lost his table of values.” It is in such cases that a talk with a tactful, sympathetic, broad-minded physician may produce the happiest results.

To assume that one can make the patient forget such worries as these without first discovering what they are, is obviously fatuity at its grossest. Moreover, as we have seen, it is quite insufficient merely to discover that the patient is “suffering from hallucinations” or delusions and then to tell him to dismiss them from his mind. To suppose that, without understanding the nature of and the specific reasons for the development of a particular hallucination, one can “make the patient forget” his interpretation of a real experience which has appealed to him night and day for weeks, or banish a delusion which is gradually becoming systematised and rationalised—_i.e._, intimately interwoven into the tissues of the whole of his experience—is an assumption which has no foundation in fact.

The point cannot be too much emphasised that many of these patients are quite sane, if conduct be regarded as the criterion of sanity; but they are growing afraid of the appearance of these abnormal phenomena, and take them for signs of incipient—or, more usually perhaps, of established—insanity. Hence follows the important corollary that while treatment by isolation has obvious advantages in certain cases, in the particular group of patients which we are now discussing it is often dangerous, for the reasons already emphasised in the last chapter. The presence of such mental phenomena is usually confided to the physician only after great hesitation, and such worrying experiences are common in cases of insomnia and other disorders, which, though troublesome,

do not appear to be grave. It is therefore possible that isolation may have serious effects in many cases in which its net result seems merely to be that the patient is no better.

It is granted then that in some instances (by no means all), the patient may be temporarily pained by the dragging into daylight of the causes of his worry, but it is usually a case of _reculer pour mieux sauter_. This procedure is often inevitable in the medical treatment of many disorders which have become complicated to any considerable extent.

We pass now to a difficult task; the consideration of the moral objections to the procedure of psychological analysis. The difficulty obviously lies in the circumstance that, while in the discussion of the other objections one could continually point to facts upon which at least, the great majority of civilised people are in cordial agreement, such unanimity is not so complete upon moral questions. Some of the varieties of the moral objection, however, are not based on such disputable grounds. For example, there is the argument that it is bad for the patient that he should have his inmost mental life dissected and analysed in the thoroughgoing way which we have described, since it is important for the preservation of his self-regard that, as far as possible, he should consider himself “master of his soul.” With the latter sentiment no reasonable person would quarrel. And where it is possible (as it often is) for a slight mental tangle to be straightened out without an extensive and lengthy inquisition, we hold that it is urgent in the patient’s interest that his privacy shall be respected. It should be pointed out, however, that since this procedure is equally in the interests of the honest physician—for it will save him time and trouble—it is likely to be adopted wherever possible. In the special military hospitals, for instance, it was often found unnecessary, in mild cases, to press the inquiry very far; the patient “learning his lesson” successfully at an early stage of the proceedings.

But it obviously does not follow that the fact of a man having for very sufficient reasons, admitted the physician into his confidence, must necessarily bring as a consequence a diminution in his self-respect. On the contrary, he often emerges from such an examination with increased confidence and a better opinion of himself, especially if, as so often happens, his self-reproaches have been unfounded. The civilised world contains a relatively large proportion of people who habitually confess their shortcomings to priests. One may recognise that the confessional has its defects, but the assumption that to have recourse to it inevitably promotes mental flabbiness is obviously unfounded. The business man who, when faced with the necessity of successfully meeting an entirely new situation, consults his legal adviser, is not usually blamed for his lack of self-reliance. Conducting one’s own legal transactions, like doctoring oneself, may appear (to the vulgar) to show independence, but its results are not always happy.

It is therefore perfectly fair to claim that none of the arguments against the use of psychological analysis have any very great significance. In some cases, however, they express valuable reminders that this delicate and powerful instrument, like all others with these attributes, must be used with care and discretion.

We may now proceed to take stock of our present position and briefly to summarise the contents of the foregoing remarks. Many cases of “functional nervous disorder” or “neurosis” exhibit as their most important characteristics symptoms, the underlying factors of which are demonstrably _mental_. A neurosis may be regarded as the failure of an act of adaptation.[45] The resultant mental disturbances do not seriously affect the “reason” or the “intellect” as was formerly supposed, but are in character predominantly instinctive and emotional. The neurotic’s behaviour in the face of an insurmountable difficulty presents a considerable resemblance to that of a child. The reasons why this analogy is not always obvious (though often it is quite plain) is that while in the child one can usually appreciate the cause of the emotional disturbance and watch its progress, these possibilities are often excluded in the case of the civilised neurotic adult. Both his insurmountable difficulty and the historical circumstances which have made it unconquerable may (they do not always) lie within his inmost mental life. Further, the child’s difficulty usually is caused simply by his inability to adjust himself to his environment; or perhaps more often to adjust his environment to himself. The adult neurotic, on the other hand, adds to these difficulties the further significant one of a lack of inner harmony. There are warring elements inside as well as outside him: he is trying to fight the enemy with an army which has mutinied.

It follows then that any attempt to restore equilibrium between himself and his social environment must be accompanied by a similar endeavour to bring about his inner harmony. Therefore, in such cases, a certain amount of psychological analysis is indispensable. Without such investigation the application of physical or psychical methods of treatment must inevitably be a shot in the dark.

The task of psychological analysis is rendered difficult by the fact that not all the motives of the patient’s present beliefs, attitudes and actions are conscious; the entry into consciousness of some of the unacceptable motives and memories is obstructed by various mental processes. When the action of these shielding mechanisms has been subverted by various means the real

significance and history of the patient's present mental condition becomes clear to him. In the light of this new self-knowledge he begins to cure himself. In a few cases he may require little or no subsequent assistance, but usually a process of re-education[46] is necessary. He may still require to be helped over some of the obstacles which he meets, and he may need more or less frequent encouragement and advice to an extent determined by his disposition, temperament, and character. By these means he is "freed from himself," liberated from the exaggerated emotional tone which has become attached to so many of his memories, and so enabled to face life anew with a harmonious and integrated mind.

The procedure which we have discussed is precisely that which the sensible mother adopts towards a child who exhibits sudden and unreasonable fear, anger, or any socially undesirable emotion. The same method is adopted towards the man who, having muddled his financial affairs, appeals for advice to an experienced and judicious business friend. "Firmness"—of the unsympathetic and unintelligent order—may occasionally produce good results in both these instances, but usually it only makes matters worse. Paying for the commercial muddler a few of his chief debts may remove his embarrassment for the time, but if unaccompanied by an attempt to reform his business methods, the result will usually be merely that such a treatment will enable him to incur fresh liabilities. So it is when a symptom or set of symptoms in a neurosis is unintelligently removed: new troubles frequently break out in fresh places.

We believe that there exist and can exist no serious arguments against the procedure of psychological analysis and re-education which we have just described. But now we come to speak of a procedure introduced during the last few years which has certainly not escaped criticism both of the most flattering and the most hostile kind. This is the method of "psychoanalysis" which we owe to Professor Sigmund Freud, of Vienna, who developed it as an extension and elaboration of the pioneer work of his former master, Professor Pierre Janet[47], of Paris.

Perhaps few terms in medicine have aroused so much misunderstanding, so much criticism, well-informed and ill-informed—and so much enmity as this word "psychoanalysis." This latter fact alone, however, should not prejudice the reader for or against it. He will probably remember that it is the exception, rather than the rule, for an innovation to be received without hostility, not only from the general public, but also from experts who work in provinces bordering upon the field in which the new method is introduced.

It should be pointed out that much of the heated discussion which has raged around this word psychoanalysis is due to the fact that the term has different meanings, as used, not only by its enemies, but by its friends. Psychoanalysis, according to Dr. Jung, is a _method_; "a method which makes possible the analytic reduction of the psychic content to its simplest expression, and the discovery of the line of least resistance in the development of a harmonious personality."[48]

Psychoanalysis is therefore a method of psychological analysis. Why, then, have we not used the term psychoanalysis in the earlier part of the book? It was purely to avoid unnecessary and acrimonious discussion on any particular doctrinal aspect of the question which this term may be taken to imply.

It is clear to every thinking person that, in analysing a mental state the physician should use every legitimate means at his disposal. If these means include, as they do, the valuable assistance derived from the study of the patient's dreams, his "associations" whether free or constrained,[49] and other mental phenomena, the doctor may use them freely without thereby subscribing to any one "doctrine of psychoanalysis."

The term psychoanalysis has been widely applied, not only to the diagnostic method, but also to the theories which underlie and determine the subsequent process of re-education. This seems to be a misuse of the useful word "analysis." It may be objected that in all scientific analysis there is some directive hypothesis to be confirmed or disproved, and that in this sense all analysis is based on theory. This is true, but it seems inadvisable to confuse the analytic process with the theory which directs one form of it.

When we come to consider the theoretical presuppositions which underlie the different methods of re-education adopted by various physicians, it is not surprising, at this early stage of our knowledge, to discover differences of opinion. The physician will find at every step that in "tidying up" the disentangled functions of the patient's mentality he will need not one theory but many, for his problem is life itself.

All his own human sympathy, with its indispensable basis, a knowledge of his own strength and weaknesses, all his learning in physical science and psychology, all his knowledge of morality and religion must be available for immediate and efficient use. In one interview he may have to lay down the law for the benefit of some ignorant and distressed patient who is desperately anxious to follow his advice unquestioningly; in the next he may be at close grips with a mind more flexible and independent than his own,

knowing well that his every little victory must be consolidated, and that every position won may be subsequently counter-attacked by his patient. He must be ready to suggest, discuss, persuade as the time and the conditions indicate.

While, therefore, the ultimate lines on which an ideal diagnostic analysis and curative re-education will be possible are as yet undefined, it would serve no good purpose in a book of this length to raise discussion on the question of psychoanalysis. Its future will be settled, not in the heated atmosphere of the debate, not in the acrid polemics of the correspondence columns, but in the calm, careful examination by the individual worker of his own actual findings and the honest comparison of them with those of others.

FOOTNOTES:

[37] Such development involves a complicated set of processes the nature of which is by no means obvious to unaided common sense.

[38] "... for example, a patient may maintain that he is the king, but that an organised conspiracy exists to deprive him of his birthright. In this way delusions are sometimes elaborated into an extraordinarily complicated system and every fact of the patient's experience is distorted until it is capable of taking its place in the delusional scheme." Bernard Hart, _The Psychology of Insanity_, Cambridge, 1914, p. 32.

[39] _Cf._ p. 15_f._

[40] _Cf._ Hart, _op. cit._, p. 66_f._

[41] The reader may pass an interesting time in trying to give himself or others an historical account of the events in his life which caused him to choose his present profession. He will probably find that memories emerge of incidents and conversations which have been forgotten for years. Yet he may find that they have influenced his present life and his action at any moment of the present, to a very great extent. Their present action clearly has been unconscious.

[42] It should not be forgotten that when a patient in an early stage of mental disorder voluntarily seeks the doctor, his _active co-operation_ in the task of tracing the causal factors of his trouble is of the greatest value. This assistance cannot be relied upon after the patient has been certified as insane and removed to an asylum, or even after he has been taken to the doctor at the instance of others. For obvious reasons he is then more likely to hide than to reveal his eccentricities. The simulation of insanity is comparatively rare: it is difficult and usually easily detected. It is dissimulation—the concealment of symptoms of disease—which is the doctor's greatest enemy. The deluded man may hide his delusions because "everyone knows that these beliefs are mad:" the melancholic may pretend for the time to be cheerful in order that his liberty may not be interfered with. (_Cf._ K. Jasper's _Allgemeine Psychopathologie_, Berlin, 1913, p. 317.) Such attitudes of the patient are obviously strengthened by our present custom of delaying the treatment of mental disorder.

[43] In his account of the wonderful exploits of "Sherlock Holmes," Sir Arthur Conan Doyle was merely applying, with inimitable skill and literary resourcefulness, the methods of clinical diagnosis in medicine to the detection of imaginary crimes. The unusual phenomenon in medicine or in crime often affords the most obvious clue to the expert who can appreciate its significance, whereas a simple dyspepsia or a commonplace murder may present insoluble problems, because they reveal no distinctive signs to guide the investigator.

[44] p. 17_f._

[45] Dr. C. G. Jung's view, _Analytic Psychology_, p. 234.

[46] It is of importance to remember that successful re-education utilises the emotional factors in the patient's mental make-up, by helping him to realise the value of the things which will make life once more attractive and worth living. In this process the more the physician knows of the patient's social, moral or religious relations, the earlier and more satisfactory will be his success.

[47] CORRECTION.

An unfortunate error in the second paragraph on page 73 escaped our notice during the correction of proofs. Professor Pierre Janet was not formerly the teacher of Professor Freud, but his fellow pupil when they were studying under Charcot in Paris.

CHAPTER IV.

Some General Considerations.

It is instructive to compare the public attitude towards insanity with that adopted in the case of another serious disease, tuberculosis.

There is nowadays a general conviction, not only amongst the medical profession but also amongst a large proportion of the educated public, that tuberculosis is a curable disease. It may exist in a mild and incipient form in many persons regarded as healthy, and, if properly treated in its early stages, with due regard not only to the actual disease in the bodily organism, but also to the healthy environment of the individual, it is almost certainly conquerable. Not many years ago, however, this happy belief did not obtain. A person “in consumption,” especially if “consumption was in the family,” was regarded as being in a very serious and almost hopeless condition. The patient, shielded from fresh air, inappropriately and insufficiently fed, often succumbed, supplying one more example to support the unscientific conception then prevalent of the inheritance of the disease. But such conditions are passing away. In our medical schools and hospitals special attention is paid to the diagnosis and treatment of early forms of tuberculosis; the importance of preventive measures is emphasised; the influence of the patient’s environment in favouring or combating the disease is explained; and the future medical practitioner is afforded frequent opportunities for personal investigation of tubercular patients. The old ideas about the “inheritance of consumption” are greatly modified. No longer is a patient’s disease explained as “in the family” and left at that. Preventive measures, early treatment, an attempt justly to appreciate the relative influence of heredity and environment are the watchwords of the modern medical attack upon tuberculosis.

If, however, we consider the attitude of the general public in this country towards the malady of insanity we find a mixture of ignorant superstition and exaggerated fear. From these there springs a tendency to ignore the painful subject until a case occurring too near home makes this ostrich-like policy untenable. The sufferer is removed to a “lunatic” asylum, neither himself nor his relatives being spared the gratuitous extra wrench to their feelings aroused by this name, which has long struck terror into the uneducated mind. He is taken away by the relieving officer of the district, often under the pretence of being given “a few weeks in a convalescent home at the sea-side,” and eventually finds himself under lock and key. Here, as is well known, he is treated with great kindness. Neither public money nor the exertions of the staff are stinted in the effort to render his lot as pleasant as possible—“the asylum to-day has become a model of comfort and orderliness.”[50] But the proportion of doctors to patients is on the average, one to 400, and it is exceedingly difficult to ensure that all patients, once inside the “lunatic” asylums, shall be regularly visited by friends from the outside world.[51] The attitude of the general public is not deliberately cruel, but it appears to be far more benevolent than it really is. The community treats the sufferer well, when, _but not before_, he has become a “lunatic.” It allows his delusions to become fixed, his eccentricities and undesirable acts to harden into habits, his moods of depression to permeate and cement together the whole of his life—and then interns him and treats him kindly for the rest of his life, but does not give him facilities for gratuitous treatment while he is still sane. _That is the British procedure to-day._

Lest we should be accused of exaggeration, or worse, we will quote here from published articles and reports.

Dr. Bedford Pierce says:—

“Let me state in a few words the defects of our present system. At present, broadly speaking, no person unable to pay its cost can receive adequate treatment until he is certified as of unsound mind. This practically means that no special treatment is possible until he has utterly broken down, and is so seriously affected as to convince a magistrate that he is decidedly insane. No general hospital will receive such a patient; the public asylums are all closed to any one who begs for protection or treatment, for county asylums cannot receive voluntary boarders even when the cost of their maintenance is forthcoming.

Consequently there is no alternative but to apply to the Poor Law authorities, who, under certain circumstances, provide treatment for a period of two weeks in the workhouse infirmary. The whole system is radically wrong. When the wife of an artisan becomes depressed after confinement, surely it is cruel in the extreme to make her a pauper and send her to the workhouse infirmary, pending a decision as to whether she is insane or no. It is obvious in such a case that this course will not be adopted until the last possible moment, and consequently much valuable time is lost.

Every practitioner will be able to call to mind patients travelling steadily towards insanity in unfavourable surroundings. This question is brought even more prominently before consulting physicians, especially those interested in nervous and mental diseases." (_Op. cit._, p. 42.)

In the words of the report of the Medico-Psychological Association:—

"The present system, which compels all persons, except those able to pay adequately for their maintenance, to apply to the Poor Law authorities in order to secure treatment, is unsatisfactory and unjust. In doubtful and undeveloped cases temporary care can be given only in workhouses or Poor Law infirmaries, which, with very few exceptions, lack proper facilities for treatment.

A system which artificially creates paupers in order to obtain medical treatment necessarily acts as a deterrent, so that too frequently there is serious and even disastrous delay."[52]

This is not exactly locking the stable door after the horse has gone; it is double-locking him thoroughly, expensively and often unnecessarily, in someone else's stable.

Let us, for a moment, compare this state of affairs with that existing in the case of tuberculosis. Nobody now believes that the scientific way of treating this disease consists in waiting until the patient has become a positive danger to others, and then locking him up. This point needs no elaboration. But another fact in this connection should not be forgotten. The tubercular patient usually seeks the doctor _of his own free will_, often obtaining treatment in a relatively early stage of the disease.

There are, however, many reasons that deter the mental sufferer from seeking medical help. One of the strongest of these is the wish to cure himself by his own unaided efforts. This is a laudable desire and one which is extremely helpful and important in mild and uncomplicated cases of relatively recent occurrence, but of which, as we have seen,[53] the gratification is not always possible. Another factor is the natural disposition which the patient shares with the rest of conventional humanity, to conceal his worries, not only from his friends, but perhaps above all from those of his own household. This tendency to concealment, however, often only aggravates his mental distress. Particularly is this the case in adolescents. As is well known, a talk with a kindly, sympathetic and wise person, or even a confession to such an adviser, frequently means the end of many painful mental conflicts.

But in addition to these very natural reasons for deferring recourse to medical help, there are in our own country special causes for delay. These are due to the prospects imagined by the sufferer to be awaiting him if he discloses his trouble.[54] The treatment of incipient mental disorder is often a long and complicated process for which the average general practitioner has seldom either the time or the special training. In very few hospitals in this country is out-patient attendance for such maladies practicable. For the mental sufferer whose means are not considerable, there exists nothing if the efforts of the general practitioners fail, but trying to cure himself, or, if he becomes worse, admission to an asylum. Unfortunately, however, the average asylum, with its one doctor to 400 patients, does not and can not meet his needs. The successful treatment of mental disease usually requires individual care, often lasting over long periods. When it is remembered that the asylums contain a considerable percentage of patients whose bodily diseases, apart from their mental troubles, require the doctor's attention, and further, that by the time the patient reaches the asylum, his disorder has usually passed through its initial stages, it is easily seen that our asylum system in its present state—to put it mildly—is far from conducive to recovery from mental disease. Considering that, in spite of these drawbacks, 33 per cent. of the patients are discharged,[55] we can only gladly recognise the efforts made by the asylums; we are, however, bound to ask: _What percentage of the inmates need ever have entered the asylum?_ It may be objected that it is easy, but unfair, to ask such a question seeing that no satisfactory answer can be given. To this objection there are two replies: first that, judging from the present state of affairs, this question cannot be publicly asked too often; secondly, that materials for an answer are already forthcoming. It is conclusively proved by the experience of other countries that a large proportion of the patients might have been cured without being sent into an asylum. Thus, for example, in Germany, in the province of Hesse, by reason of suitable treatment during the early stages of mental illness the authorities were able to postpone for ten years the erection of a new asylum.

"The Psychopathic Hospital at Boston, Massachusetts, ... was built by the State expressly to deal with recent acute cases. No fewer than 1,523 patients were received in its first year, and of these 590 were received under a temporary care law, which provides for a week's detention only; large numbers were also received on a voluntary basis, so that during the year _48 per cent. of all patients escaped the usual lunacy procedure_.

On reading the reports of work done, one is struck with the enthusiasm of the medical staff and the vast field of research undertaken. During the two years eighteen medical men describe their work covering almost every department of psychiatry:

juvenile crime, tests for feeble-mindedness, incidence of syphilis, alcoholism, hydropathy in its influence on red blood cells, treatment of delirium, prophylaxis, analysis of genetic factors, salvarsan treatment, tests of cerebro-spinal fluid, and last, but not least, the value of out-patients' departments and after-care. There is a special social service department for the purpose of following up cases in their homes, and it was found that of every 100 admissions 20 needed supervision on discharge, 24 needed advice, 3 required assistance in arranging their discharge, and 10 showed a need for prophylactic work in their families.

This bald statement of the activities of the Boston State Hospital shows plainly what an important service it renders in providing treatment apart from ordinary asylum associations. It shows how it is possible at such a hospital to organise a medical service which covers all departments of psychiatry; and further, that when the mental symptoms clear up, a patient need not be thrown back into old associations without help or supervision.

This hospital at Boston is but one of many that have been established in the United States in recent years. Some of the others are due to private munificence; in particular, reference may be made to the Henry Phipps Psychiatric Clinic at Baltimore, the medical staff of which consists of a director, assistant director, a resident physician, two assistants, and five [resident medical officers]. In addition to these are the heads of three research laboratories dealing (1) with clinical pathology and bio-chemical investigation, (2) with neurological research, and (3) with psychopathology." (Bedford Pierce, _op. cit._, p. 42.)

In advocating the establishment of separate pavilions for nervous and mental disease in direct association with the general hospitals, Dr. Bedford Pierce says:—

"At La Charité Hospital in Berlin, the visitor enters a small park, and Dr. Ziehen's clinic is but one of many detached buildings devoted to special diseases. It is as easy and simple for the patient suffering in mind to get advice there as for another with eye and lung trouble."

Let it be noted that none of these German patients, on returning to their relatives and friends, suffer from the stigma of having been to an asylum. In our country some of those same friends during the patient's absence would often have been engaged in "sympathetically" spreading the news of the sufferer's absence and his whereabouts to everybody in the district. To a certain type of mind there is a ghoulish fascination in gloating over the illnesses and afflictions of neighbours. Even though people addicted to such habits may salve their own consciences by exclaiming "poor fellow" at the end of their narrative, the effect of their conduct is none the less brutal and offensive. This is not the place for the discussion of so remarkable and important a phenomenon of social psychology. Nevertheless it plays a great part in the causation of the prevalent dread of treatment for mental disorder.

For many reasons the psychiatric clinic is not regarded by the public as a "lunatic" asylum. In the Giessen clinic in Germany, for instance, both nervous and mental diseases are treated. The patient afflicted with tremor or a paralysed finger visits this institution as well as the sufferer whose troubles if neglected might develop into mental disease. Difficult medico-legal cases resulting from such incidents as those arising from the claims by workmen and others for compensation after accident are sent to this clinic for observation and opinion. "Rest-Cures" and similar treatment are also carried out there. The official title of the institution, displayed at the entrance, is "Clinic for Mental and Nervous Diseases." The institution is therefore regarded by most people in quite a different light from the asylum, and it is not spoken of by the general public with bated breath. One of us, while working in the laboratory of a German psychiatric clinic, was introduced to a visitor who made some remark about "when I was here." To the question, "Were you on the staff, then?" the visitor answered quite naturally, "Oh no, I was here as a patient."

With this experience may be contrasted another incident, this time from our own country. Delegates from a certain Board of Guardians paid a visit to the county asylum to inspect the arrangements made for the comfort of the inmates from their own district. In the next week's local newspaper a report of the visit appeared in the form of the chief delegate's speech at the subsequent board meeting. This report consisted of "funny" stories of the eccentricities of the patients the visitors had seen, and of the delusions from which some of the victims were suffering, with sufficient detail to enable many of the relatives, and possibly some of the friends, of these "lunatics" to identify the afflicted ones. The newspaper account of this humorous effort was punctuated at suitable intervals with "laughter."

It is obviously not claimed that these two accounts are typical either of Germany or of England. But what is claimed is that of these two public attitudes the clinic system promotes the one, the "lunatic" asylum the other.

Before leaving the comparison of insanity with tuberculosis we must remind the reader of some other facts that are important in this connection. We have seen[56] that the scientific study of tuberculosis has materially modified the earlier views concerning its

hereditary transmission. It is now held that tuberculosis is not inherited as such; but that a child of tuberculous parentage may begin life with a subnormal power of resistance to the disease and perhaps greater risk of exposure to infection. If later he develops the disease, it is traceable directly to his environment. The corollary is that if his environment be improved, and his body's power of resistance increased meanwhile by all the means in our power, he has a considerable chance of living a life free from the disease. Thus the old pessimistic view is replaced by a distinctly optimistic one.

In the mental disorders that are indubitably traceable to organic disease of the central nervous system, heredity doubtless plays a great role. But two points should be remembered in this connection. First, among asylum patients the number of mental disorders which cannot, _post-mortem_, be traced to organic causes is very great as compared with those that can be so related. For example, of 1,325 patients received at the Burgholzi Central Asylum and University Psychiatric Clinic, Zürich, Dr. C. G. Jung states:—

"... in round figures a quarter of our insane patients show more or less clearly extensive changes and destruction of the brain, while three-fourths have a brain which seems to be generally unimpaired or at most exhibits such changes as give no explanation of the psychological disturbance.... We must take into account the fact that those mental diseases which show the most marked disturbances of the brain end in death; for this reason the chronic inmates of the asylum form its real population, and among them are some 70 to 80 per cent. of cases of dementia præcox, that is of patients in whom anatomical changes are practically non-existent."[57]

In a great number of mental disorders our present knowledge of anatomy, physiology and pathology is of little help as a means of throwing any light upon the patient's condition. While in no way attempting to belittle the magnificent work in these subjects during the past century, it should be pointed out that its very success has brought about, especially in this country, an unfortunate tendency to regard these methods as the only ones suitable for attacking the problems of insanity. But nothing is more certain than that in the psychoneuroses: hysteria, neurasthenia, psychasthenia and the rest, anatomical and physiological knowledge has not yet passed beyond the theoretical stage[58]. But it is equally indisputable—and the statistics of shell-shock cases have strengthened the evidence for this assertion—that the psychological mode of attack, the treatment of mental disorder by mental means, is now firmly established as a practical method.

It appears, therefore, that precisely in those cases of psychoneurosis which yield to psychical treatment, there is no anatomical, pathological or chemical evidence of inheritance.

But while the contributions of anatomy, physiology and pathology to the treatment of psychoneuroses have not yet gone beyond theoretical and mutually conflicting suggestions, the psychological method of investigation and treatment on the other hand has proved itself of practical use in restoring patients to a normal state of mental health. What scientific justification therefore have we, when considering the action of heredity, for lumping together the organic and the functional mental disorders? The psychoneurosis is often simply a progressive state of mal-adaptation to environment; a mental twist which can be corrected if treated suitably at a sufficiently early stage. Its specific nature is frequently explicable almost entirely in terms of the peculiar educational, family or social relations of the patient's environment. The war has shown us one indisputable fact, that a psychoneurosis may be produced in almost anyone if only his environment be made "difficult" enough for him.[59] It has warned us that the pessimistic, helpless appeal to heredity, so common in the case of insanity, must go the same way as its lugubrious homologue which formerly did duty in the case of tuberculosis. In the causation of the psychoneuroses, heredity undoubtedly counts, but social and material environment count infinitely more.

To some readers the above argument may seem so obvious as to be superfluous. To ascribe a patient's entangled state of mind to heredity without attempting to discover how far his own personal experiences have tended to bring about that mental condition, would seem as fatuous as attributing to heredity the financial muddles of a son who has inherited from his unbusinesslike father a badly managed estate. The trade-adviser called in to help might for a moment consider the possibility that the son may have inherited his father's unpractical character, but surely his first serious efforts would be to discover where the business methods were wrong or antiquated and to improve on them. So it is with the mental patient; his own history is the important desideratum. That of his parents may cast valuable light upon his trouble, but even then it is often just because their own difficulties have contributed to the making of his environment.

One of the most dangerous and misleading terms in our language is the word "neuropathic;" for it is made to signify so many things that it ends by meaning nothing. Etymologically, it should mean "afflicted with disease of the nerves," a conception the precision of

which we shall discuss below. Yet on the return from the front of patients afflicted with “shock” one heard the opinion at first that the cases were those of “neuropathic” men: that the soldiers who became affected by shock were weaklings or were descended from mentally afflicted or nervous parents. It is, of course, unquestionable that in a large army there must be many soldiers with tainted family histories; and it is probably equally certain that such factors play some part in determining the greater susceptibility of certain men to shock. But it would be a gross misrepresentation of the facts to label all the soldiers who suffer from mental troubles as weaklings. The strongest man when exposed to sufficiently intense and frequent stimuli may become subject to mental derangement. It is quite common to find among the patients suffering from shock senior non-commissioned officers who have been in the army fifteen or twenty years (much of which time has been spent in foreign service under trying circumstances, such, for example, as the South African War), and have stood this severe strain. Such men can hardly be called weaklings or “neuropathic.”

Even in those cases where there is a definite history of a neurotic parent, it would be a mistake hastily to conclude that when the son of such a man or woman becomes a victim of shell-shock it is due to heredity. For when the detailed history of such patients is obtained the fact comes out quite clearly that the social disturbances in the household of such a nervous person may be amply sufficient to inflict severe psychical injuries upon young children.

Further, in many cases the histories themselves clearly and definitely reveal the real etiology of the mental condition, and point to emotional disturbances in children, due to the cruelty of drunken parents, a rankling sense of injustice, a terrifying experience, which may have been an accident or deliberate maltreatment by some human being, or again, to the appalling conditions created in some of these homes by nervous and irritable parents, as the real trauma which the “shock” has served to re-awaken.

But when we come to ask _what_ disease of the nerves, or, more strictly, of the nervous system, is implied in speaking of the “neuropathic” we find no satisfactory answer. Certainly no one disease is regarded as being the causal factor. And the list of theories is overwhelming. Disturbances of the genital, vaso-motor, or digestive systems, demineralisation, chemical disturbances of nutrition of hepatic or cholæmic origin, visceral ptosis, cerebellar disturbance, thyroid disorder, complex disturbances in functioning of the blood vessels, intoxication, exhaustion[60]: these are some of the numerous theoretical suggestions proposed to account for neurasthenia only. Whether the unfortunate neuropath is supposed to be afflicted by one or all of these is a matter which we certainly cannot decide; for the theories proceed from many different sources.

But we must not lose sight of another important fact in this connection. The neuropathic person’s mental troubles, or those at least for which he seeks relief from the physician are by no means in the clouds of theory. They are real enough, and as a rule not to the patient only, but also to his relatives and friends, with whom he finds it difficult to live amicably. Those troubles are based upon fear, anxiety, anger, and excessive curiosity concerning matters about which the normal person would not bother his head. They find expression in outbursts of pugnacity or of unusual self-assertion with its emotion of elation, often followed by self-abasement and subjection, inordinate desires either to be alone or never to be alone, floods of tender emotion, possibly following close on the heels of a mood of blatant self-assertion with no regard for the feelings of others. These relatively simple processes of mind, occurring sometimes in comparative isolation, sometimes inextricably blended or kaleidoscopically transient, are the real marks of the so-called neuropath or neurotic. Bodily troubles may, and often are, added to these. But as every physician knows to his cost (and sometimes to the patient’s), and as faith-healers know to their advantage, these bodily diseases are usually exaggerated by the neurotic sufferer, and frequently prove to have but a slight material basis. In other words, the real marks of the “neurotic” are mental.[61] And one need not be a technical psychologist to see that the above list is nothing but an enumeration of the instincts and emotions possessed in common by all men.[62]

If then, the neuropath is merely displaying instincts which are common to all mankind, what is the difference between him and the normal human being? The difference is psychologically slight, sociologically immense. While his normal brother reacts instinctively and emotionally to his physical and social environment in such a way and to such a degree as to promote his own welfare and that of others, the neuropath does not. Nobody calls the townsman a neuropath who before crossing the street waits on the pavement until the stream of traffic has thinned. If he did not wait we should rather call him a fool. But the instinct of fear is largely at the bottom of his so-called intelligent caution—especially if he has ever witnessed a distressing street accident. But what do we say of the man who waits and waits until finally he is too afraid to advance, eventually stealing down to another place so that he may cross in safety? He is very likely to be called a neuropath. Or what shall we say of the unfortunate man whose caution has gone so far that he cannot cross _any_ open space whatever, and is said to be suffering from agoraphobia?

Or again, take the case of a man whose personality, family or country, is grossly and publicly insulted. If he strikes at the aggressor, do we call him neuropathic? But we seldom hesitate to apply this term to the man who is inordinately touchy, ever on the watch for

the least suspicion of insult towards himself or anything even remotely connected with him. The emotion of fear underlies both the attitude of caution and of “funk,” that of anger, the righteous indignation of the stalwart and the querulous, peevish irritability of the neurasthenic. The difference between the behaviour of the normal man and the neuropath lies primarily in the circumstances that provoke emotion in them, and secondly in the violence and duration of the emotion itself.

We should remember also that many varieties of animals display the kind of behaviour we have described, and regard as so unusual, if not utterly eccentric, in our friends. Professor William James reminds us of the chronic agoraphobia of our domestic cats; and the tamer of wild animals has good reasons to respect the incessant touchiness of some species of the genus _Felis_. Do we invoke theories of visceral ptosis, intoxication and the rest to explain the behaviour of the average cat or mule? Scarcely. We say that these animals are actuated by instinct. Our arrogance makes it difficult for us to suppose that our suffering human brothers are also acting instinctively. Yet this is undoubtedly the case.

It has been said of the neurasthenic with aptness and truth that he behaves like a child. But if a child, normal in its behaviour up to a certain day, suddenly manifests fear of being left alone for a moment in a room with closed doors, or in a street, do we rush for our “Liddell and Scott” and forthwith proceed to babble of claustrophobia or agoraphobia?[63] Do we follow this up by solemnly invoking complicated physico-chemical theories concerning the state of his blood or other bodily fluids? Finally, do we brand him as “insane” or at least “neuropathic?” What we do in this case, if we have any sense, is carefully to investigate the causes of the emotional outbreak. We try sympathetically to understand and re-educate the child to meet such situations without fear. In other words, we use a method precisely similar to that which proves to be of such great use in treating the psychoneuroses.

The analogy—if it be an analogy and not perhaps an identity—between the two cases goes still farther. The child who manifests extreme fear at “inadequate” causes, such as we have described, not infrequently agonises his mother—perhaps soon after his outburst of fright—by an exhibition of foolhardiness which, if we did not know of the previous sign of weakness, would cause one to look upon him as fearless. In short, the child’s fear is restricted to one or two special situations. So it is with many neurasthenics. Some, for example, may be driven through traffic in a fast motor car without experiencing the slightest fear, though they cannot bring themselves to enter an ordinary slow suburban train; others may surprise us not only by their exhibition of anger at what we should consider an absurdly slight provocation, but by their tolerance and self-control in other (to us) much more annoying situations. Their exaggerated emotional reactions are excited not by general but by specific stimuli; and a little tact, insight and patience on the part of the physician often reveals in their past experience, psychological factors which explain the tremendous personal importance and overweighting of these stimuli. If for neuropathic we write: “unduly hampered by instinct and emotion”—and this is all we have the right to do[64]—we represent the matter more truthfully.

Among the laity, before the war, the justification of an attitude of inertia towards the treatment of mental disorder (more particularly of the psychoneuroses) was often based upon two statements. The first was that many of the phenomena reported were not real, but were the imaginings of hysterical women. If to this it was objected that men were not immune to hysteria[65] one was met by the retort: “But they are ‘neuropaths.’” This war has, however, removed from honest people’s minds the possibility of regarding these phenomena in such a shamelessly unscientific light. In the military hospitals there have been hundreds of patients suffering from psychoneuroses, who are demonstrably neither women nor neuropaths, in any of the legitimate senses of these terms. And many of these men have suffered intensely. Their fears and other emotional troubles are such as they usually conceal as long as possible, until further endurance is intolerable. Their troubles are real enough to them. “But they are unreasonable,” the healthy philistine may object. Some (by no means all) of the fears _are_ unreasonable, if by that is meant that the actual danger (as the healthy man estimates it) and the emotion which it evokes in the patient are entirely disproportionate. But who among us has “sized up” life’s dangers so accurately that he can say he knows the precise degree of fear which each one _ought_ to evoke?

In some country places the inhabitants to-day are more afraid of the presence in their houses of peacock’s feathers or of hawthorn blossom than of scarlet fever. Their fears are unreasonable. But we do not call these people neurasthenics. As a matter of fact, neurasthenia is one of the last diseases likely to attack these rustics. If they vouchsafe any reason for their fear, it is safe to assert that it will be a rationalisation, for its real sources are hidden from them. And if we really wish to discover the cause of their fear we turn for help to the records of folk-lore and ethnology. In other words, we investigate the history of the fear. This history may go back many centuries and the process of recovering it from a series of clues will prove a task of infinite fascination. Now the history of the neurasthenic’s fear is likewise obtainable and much more easily, for it is of much more recent date. Its discovery often means the freeing of a mind from torment, the restoration of a useful member to society, and the enrichment of the science whereby other similar liberations may become possible. But how few investigators, as yet, have been attracted by this tremendous unfilled field of knowledge!

However, our philistine, while agreeing to this, may, and often does, change his ground. He may add: “When I said that the phenomena were not real I had in mind rather the pains and the paralyses from which the hysteric and neurasthenic suffer—or say they suffer.” To this we may answer in the words of Dr. Purves Stewart:—

“... we must recognise that the neuroses are real diseases, as real as small-pox or cancer. A sharp distinction must be drawn between a hysterical or neurasthenic patient and a person who is deliberately shamming or malingering.... The hysterical or neurasthenic patient usually has no knowledge of the disease which he or she may unconsciously simulate. The various paralyses and pains from which hysterics and neurasthenics suffer are as real to the patient as if they were due to gross organic disease.”[66]

There is a view which, while eminently useful and sensible in so far as it concerns neurology alone, is apt, by virtue of these good qualities, to retard the progress of psychical treatment of the neuroses. For it tends to focus the attention of the medical world on their physical basis alone. Such a view is expressed by Dr. Purves Stewart in the manual from which we have just quoted. In his chapter on the neuroses he says:—

“The old definition of a neurosis as a nervous disease devoid of anatomical changes is inadequate. _Disease is inconceivable without some underlying physical basis._[67] The lesion need not be visible microscopically: it may be molecular or bio-chemical.”[68]

Now from the purely material standpoint such a statement is above reproach. But some important reflections occur as one thinks over the paragraph, and especially the statement: “Disease is inconceivable without some underlying physical basis”—as applied for example, to neurasthenia. What are the important signs of disease in the neurasthenic, or what unusual phenomena are there which cause him to seek the doctor? Chiefly, as we have seen on p. 91, the undue dominance in his mental happenings of instinct and emotion. But we cannot say that this by itself is a sign of disease. Otherwise we shall arrive at the paradoxical conclusion that wild animals, savages and children form the diseased class _par excellence_.

The behaviour of the neurasthenic differs from that of the normal person only in degree, and some sane men might be unhesitatingly regarded as neurasthenic by one class of society, normal by another.[69]

Moreover, it is perfectly clear that if we adopt any of the usual views as to the relation between body and mind, not only disease, but health too is “inconceivable without some underlying physical basis.” Yet of the molecular or bio-chemical aspects of that basis we know practically nothing which would help us to understand even ordinary mental occurrences. So when a normal, physically healthy mother bursts into tears of joy on her son’s return from the front, is sleepless when she knows he is in the trenches, forgets some of her daily duties in perpetually thinking of him, is “on edge” and irritable when she has had no letter from France—though we may be perfectly justified in believing that there are molecular or bio-chemical nervous changes underlying her behaviour, we do not dream of invoking these as explanations of her condition, for of them we know little. Neither do we call her neurasthenic. We understand her condition in that we correctly refer it to the action of instinct and emotion. Its cause is clear to us, and if we attempted to treat it we should know beforehand that the best cure would be the restoration of her loved one, the next best, sympathetic help in facing her worries, the removal of unfounded fears and the production of a serener outlook on the future. In other words, the diagnosis, the tracing of causes, and the treatment would be entirely mental, with no reference whatever to the physical basis, the existence of which we obviously should not deny. Similarly, if a man is troubled by a great moral conflict which produces in him sleeplessness, irritability, abstraction and the rest, the physical basis of his emotional condition may be “materially” treated. His sleeplessness may be reduced by bromides, his irritability and depression by alcohol; but who, if he knew of the great mental conflict, would dare merely to prescribe these?

And this, in the case of many of the psychoneuroses is the crux of the whole matter. The root of the trouble is mental conflict, the complete details of which can seldom be found on the surface of the complex of symptoms. To palliate them one by one is often to provoke new ones. The conflict is sometimes clearly apprehended by the patient, but even then is often jealously guarded from everyone else. Sometimes, however, it is not clearly conscious in all its details, even to him. This is especially the case, if as so often happens, he habitually shuns the thought of it. Faced with an inability to adapt himself to his circumstances, he instinctively relapses into a more childish way of meeting the situation—hence the tears, the irritability, the mental distraction and the rest. This phenomenon, we repeat, is not new. We all acknowledge its existence when we say that the “nervy patient behaves childishly,” though perhaps we do not realise what a true conception of the matter we are expressing.

To sum up, while it is indisputable that the psychoneuroses, like all mental phenomena, have a material basis, we should clearly distinguish between fact and theory in our existing knowledge. Every doctor will naturally seek to make the fullest use of his

learning in building up the bodily health of the neurasthenic. But to sit with folded hands and wait for the advancement of our knowledge of microscopic anatomy, physiology or bio-chemistry would be fatuous when there are other and more direct means of treating the numerous and often pathetic cases, which urgently call for cure. The view that “disease, like health, is inconceivable without some underlying physical basis” is sound and useful, but must not be allowed to blind us to the vital significance of the mental factor and its corresponding importance in the diagnosis and treatment of “functional” disease.

It is an indisputable fact that many modern physicians are apt to concentrate their attention almost exclusively upon the bodily ills of their patients. Yet the majority of doctors, especially those who in general practice get to know their patients intimately, admit readily, even eagerly, that not a small number of the maladies which come under their notice are seriously complicated, if not dominated, by mental factors. To take a simple and obvious example, insomnia may be caused by distressing mental conflicts quite as often as by physical disease. The doctor, however, even if he suspects this fact, often hesitates to proceed further in the light of such knowledge.

For this there are several reasons. In the first place, his arduous, lengthy and expensive medical course has usually never vouchsafed him five minutes’ specific training concerning the manifold ways in which human nature may succeed or fail in adapting itself to the complex environment which we call civilisation. Any wisdom of this kind that he has picked up is due to his own interest and insight in social matters. The university’s contribution to his psychological knowledge usually consists in showing him a handful of comparatively hopeless caricatures of mentality in his short series of visits to the asylum.[70] It is as if one tried to teach electrical engineering by a few exhibitions of broken-down dynamos, navigation by half-a-dozen cursory inspections of wrecks, finance by a short series of visits to the bankruptcy courts.

The result of this strange conception of medical education is different according to the mental make-up of the particular physician. There are many whose insight and sympathy enable them to penetrate successfully for some distance into the Cimmerian darkness of the patient’s mental troubles. But do we believe that insight and sympathy alone are sufficient for the successful diagnosis of disorder or disease of the heart or lungs? Mental disorder is subtler, more varied than these, but like them it proceeds along definite lines in definite situations, and it is capable of description even as they are. It is therefore insufficient even for the talented doctor to rely entirely upon his natural gifts. But in what other branch of science would it enter his head to do so?

But not all doctors happen to be of the type we have described. There exist many excellent practitioners who are temperamentally so constituted that to them these unaided excursions into the investigation of mental trouble would never suggest themselves. Predominantly objectively-minded,[71] “without a nerve in their bodies,” calm and confident, practical and quick to apply their knowledge in the physical sphere, they have no natural inclination towards the study of such disorders as we have mentioned; and their teachers have too seldom done anything to supplement the exclusively materialistic studies[72] of their medical course. When, as not seldom happens, he is faced by a case of hysteria or neurasthenia, such a practitioner is inclined to regard the malady, if it does not prove tractable by rest, change, drugs and diet, massage, electricity, etc., either as “fanciful” and requiring firmness unveiled or veiled,[73] or as the beginning of a lamentable and grave attack of mental disorder. Unfortunately the number of cases yielding to firmness is not gratifyingly large. The hysterical patient, too, has a will of his own, and frequently proves this fact in a disconcerting manner. The neurasthenic, knowing long before the doctor tells him, that he ought not to worry, that he ought to “buck up,” frequently becomes acutely critical of his physician, and his powers of judgment are all the keener for their frequent whetting upon his own deficiencies. Not that he should not worry, but _why and how_ he should not worry is what he wants to know.

This criticism of the brusque, cheery way in which such a physician may treat mental troubles is not meant to be one-sided or unfair. For some patients, the “firmness” treatment is the right one; others may be so impressed by the doctor’s cheery personality that they recover. But it is safe to say that these are seldom serious cases. The intelligent, highly moral, over-worked business man must not be given the same treatment as the society lady suffering from lack of honest labour—and nobody knows this better than the patient.

This objective way of regarding cases of neurasthenia readily tends on the one hand to make the physician underrate their importance (as when he expects to cure them with “firmness”) and on the other, when they prove impregnable to such attacks, to cause him to exaggerate their seriousness. For, he may argue to himself, if they are beyond cure in this way, what is to be the future of the patients except permanent eccentricity or even insanity? Only a deeper knowledge of the subject can save him from this top-heavy oscillation from unfounded optimism to equally baseless pessimism.

We have noted two of the common obstacles which obstruct the path of the physician anxious to treat mental disorder: his own lack of training and, in not a few cases, his temperamental inclination to look exclusively for visible and tangible material evidence of disease. There is, moreover, at present another serious obstacle consisting in a widespread social convention. This is the unwritten law which commands a person to hide any troubles of a mental nature not only from his friends, but even from his doctor, though he may speak of his physical disabilities to everybody with unblushing frankness. Much could be written on this subject, but the inconsistency of the current attitude has been satirised with inimitable wit and humour by Samuel Butler.

His whimsical fancy has created a civilised country in which this convention does not exist; in which, in fact, the opposite belief obtains. In that land, while a man's bodily ills are counted a disgrace, and not to be mentioned, his mental troubles are regarded as physical illness is with us. The name of that country is _Erewhon_. In _Erewhon_, we are told, physical illness is not only considered shameful but is punishable by imprisonment. Mental trouble, on the other hand, even irritability or bad temper, is regarded as illness requiring the attention of physicians, known as "straighteners." And the consequences of this are that a man will dissimulate the existence of indigestion, giving out that he is being treated for dipsomania, while in answer to questions about his general condition another will quite freely and truthfully say that he is suffering from snappishness. We in England, says the explorer,

"never shrink from telling a doctor what is the matter with us merely through the fear that he will hurt us. We let him do his worst upon us and stand it without a murmur, because we are not scouted for being ill, and because we know that the doctor is doing his best to cure us and that he can judge our case better than we can; but we should conceal all illness if we were treated as the Erewhonians are when they have anything the matter with them; we should do the same as with moral and intellectual diseases—we should feign health with the most consummate art till we were found out...."

This convention inevitably influences the "straightener's" attitude towards his patients, as we are told by the traveller in a description of an interview between his host and an Erewhonian doctor:—

"I was struck with the delicacy with which he avoided even the remotest semblance of inquiry after the physical well-being of his patient, though there was a certain yellowness about my host's eyes which argued a bilious habit of body. To have taken notice of this would have been a gross breach of professional etiquette. I was told, however, that a straightener sometimes thinks it right to glance at the possibility of some slight physical disorder if he finds it important in order to assist him in his diagnosis; but the answers which he gets are generally untrue or evasive, and he forms his own conclusions upon the matter as well as he can. Sensible men have been known to say that the straightener should in strict confidence be told of every physical ailment that is likely to bear upon the case, but people are naturally shy of doing this, for they do not like lowering themselves in the opinion of the straightener, and his ignorance of medical science is supreme. I heard of one lady, indeed, who had the hardihood to confess that a furious outbreak of ill-humour and extravagant fancies for which she was seeking advice was possibly the result of indisposition. 'You should resist that,' said the straightener, in a kind, yet grave voice, 'we can do nothing for the bodies of our patients; such matters are beyond our province, and I desire that I may hear no further particulars.' The lady burst into tears and promised faithfully that she would never be unwell again."

[58] “Everybody agrees,” say Déjerine and Gauckler (_op. cit._, p. 214_f_), “that neurasthenia is a neurosis, _i.e._, a nervous disease without any known lesions.... Neurasthenia is due wholly to psychological factors which are essentially, if not exclusively determined by emotion.” They then proceed to compare the “materialistic” theories of neurasthenia, showing that they are all still merely speculative.

[68] p. 355.

[69] This was seen repeatedly in the treatment of the relatively uneducated soldiers who had become slightly neurasthenic as a result of the war, especially of those whose life had been spent in open-air manual work, or in the strict and healthy routine of the regular army. They complained of emotional irritability, minor lapses of memory such as the forgetting of relatively unimportant names or of errands, disturbed sleep, soon “getting fed up” with their amusements (_e.g._, “jig-saws,” or billiards for hours every day, month after month in a converted schoolroom or outhouse!). Not only did these phenomena disturb them, but in a great many cases they seemed to prove to these unfortunate men that they were insane, or rapidly becoming so. They would anxiously ask such questions as, “What is it that makes me so irritable at a slight noise, or at being brushed against by another patient? I used not to be like that.” Their conduct was also regarded as unusual by their companions. Now would not the head of a business firm, an over-worked medical man, a university professor or an army officer in a position of responsibility, confidently expect to be allowed _ex-officio_ a certain number of these eccentricities without being called “diseased?” But let him drop the privileges and shelter of his rank, live for a few weeks as a private in a barracks with a number of high-spirited and thoroughly healthy soldiers and his behaviour might certainly be considered by them to be queer, if nothing worse.

[70] Reform of this state of affairs is urgently needed. The matter is of such fundamental and far-reaching importance that we have devoted part of the next chapter to the further consideration of its bearings.

[71] “Tough-minded,” “matter-mongers,” modern writers have called this type, contrasting it with that of the “tender-minded,” “reason-mongers.”

[72] Of a brilliant teacher of physiology, one who was himself intensely interested in the sciences bordering on his own subject, it was related that when, in lecturing upon the functions of the nervous system in man, he approached difficult problems, he used to say, “But that is a matter for the psychologist.” Whereupon the class heaved a sigh of relief and prepared to take notes upon the next subject.

[73] “... strong electric shocks, cold douches, and other decorous substitutes for a sound birching.” W. McDougall, _Psychology_, London, 1912.

CHAPTER V.

Some Lessons of the War.

Are we, as a nation, doing all that we should for the mentally afflicted? This is the question—no less urgent and important now than it was a century ago—to which we call the serious attention of the reader.

It is no new discovery to recognise the immediate importance of its proper consideration, of the honest facing of the present conditions, and of the urgency for such reform as shall lead to an affirmative answer to our question. Already it has been the subject of considerable discussion in recent medical literature, and in the medical press numerous efforts have been made to bring it to the attention of the general public. In July, 1914, the Medico-Psychological Association of Great Britain and Ireland, a body composed chiefly of the medical officers of our asylums, issued the report of a special committee which had been appointed, in November, 1911, to consider the "status of Psychiatry as a profession in Great Britain and Ireland, and the reforms necessary in the education and conditions of service of assistant medical officers." Unfortunately, within a few weeks of its publication, the outbreak of war prevented that discussion of the question which would otherwise assuredly have followed the publication of so momentous a statement. For in the report stress was laid on the "absence of proper provision for the early treatment of incipient and undeveloped cases of mental disorder," on the lack of adequate "facilities for the study of psychiatry and for research" and upon "the unsatisfactory position of assistant medical officers" in the asylum service. Clearly the stressing of such points by a committee, thoroughly competent to form a judgment in such matters, compels a negative answer to our leading question. The report makes it perfectly clear that this country has grievously lagged behind most of the civilised nations in the treatment of mental disease.

Yet all attempts in the way of important and far-reaching reform have been frustrated, at least during times of peace, by a strange state of indifference and inertia and by lack of knowledge. Thus, even so recently as January 15th, 1916, the _British Medical Journal_ was responsible for the statement "The only hope that our present knowledge of insanity permits us to entertain of appreciably diminishing the number of 'first attacks' lies in diminishing habitual and long enduring drunkenness and in diminishing the incidence of syphilis."[74] This statement would have been sufficiently amazing if it had been made three years ago; but when the hospitals of Europe contain thousands of "first attacks" of insanity, which are definitely _not_ due either to alcohol or syphilis, the only conclusion to be drawn is that its author must have been asleep since July, 1914, or have become so obsessed by a fixed idea as to be unable to see the plain lessons of the war. Syphilis, no doubt, is responsible for a considerable number of cases of insanity, and drink perhaps for some more[75]; but the incipient forms of mental disturbance which the anxieties and worries of warfare are causing ought to impress even the least thoughtful members of the community with the fact that similar causes are operative in peace as well as in war, and are responsible for a very large proportion of the cases of insanity. But—and this is still more important—it is precisely these cases which can be cured if diagnosed in their early stages, and treated properly. The chief hope of reducing the number of patients in the asylums for the insane lies in the recognition of this fact, and in acting on it by providing institutions where such incipient cases of mental disturbance can be treated rationally, and so saved from the fate of being sent into an asylum. We may refer the reader to p. 82 _et seq._, on which was given a short account of the success of these reforms. We reiterate some of the advantages of the clinic system—treatment of the patient without the necessity of the ordinary asylum associations and the consequent social stigma; and the considerable reduction in the number of patients requiring internment in asylums which has followed upon the establishment of the psychiatric clinic.

In this country insuperable obstacles in the way of this urgent reform have been raised by our distinctive national obstinacy, and our blind devotion to such catch-phrases as "the liberty of the subject,"—even when this involves the eventual incarceration of the patient whose liberty to escape treatment and to become insane, is the issue jealously defended. Now, however, the stress of war has compelled us to see matters in another light. The present war, which has been responsible for destroying so many illusions, has worked many wonders in the domain of medicine.

The rational and humane treatment of early cases of mental disturbance has now been inaugurated on precisely those lines which have been so long urged, with such little success, by the more far-seeing members of the medical profession.[76]

A good example of this reform is the splendid work now being carried out, at the Maghull Military Hospitals, near Liverpool, for officers and men, organised and superintended by Major R. G. Rows. The institutions are specially devoted to the treatment of soldiers suffering from "shock" and other psychoses. The success already achieved there is sufficient evidence of the great value of these special hospitals for the treatment of nervous and mental disorders in their early stages.

But if the lessons of the war are to be truly beneficial, much more extensive application must be made of these methods, _not only for our soldiers now, but also for our civilian population for all time_. We have before us the practical experience of those countries which have undertaken this great experiment in preventive medicine, yet apart from the encouraging results of its treatment practised in our special military hospitals, its present position in this country is only too accurately described in the report to which we have referred. With few exceptions[77] “the subject (of mental disease) is left severely alone.”[78] Our arm-chair writers direct their attention to safer subjects, such as eugenics, for example, and here they can be happy in feeling they are on secure ground, because they are aware that their neighbour knows little more about it than they do. Or they inspire reports, and I quote a sentence from a recent report as a contrast to the encouraging sound of the word ‘recovering.’[79]

In the _Standard_ newspaper a few days ago, (_i.e._, in 1914) there was a reference to a report issued by the London County Council in which one paragraph began with the statement, ‘Once a lunatic, always a lunatic.’ This is the message sent in this country to our sufferers, a message as brutal as it is unjustifiable. Again, in the _Standard_ of February 11th in the year of grace 1913, there appeared the statement that ‘the Camberwell Guardians have issued instructions that the use of “anklets” on violent lunatics in their institutions is to be discontinued.’

With reference to the dictum “Once a lunatic always a lunatic” we should like to call attention to another statement in this report. “The fact that, _even under the present conditions of delayed treatment, about 33 per cent. of those admitted to the asylums of England and Wales are discharged recovered_, demonstrates that the feelings of helplessness and hopelessness, with which such illnesses are usually regarded, are by no means justified. The evidence of many authorities who have had practical experience of the value of treatment during the incipient stages of the illness, shows conclusively that the exercise of scientific care during the early phases of mental disorder would save many from such a complete breakdown as would necessitate certification and removal to an asylum. In all other branches of medicine facilities for dealing with disease in its initial stages are recognised as indispensable and therefore the Committee regard it as essential that, in the large centres of population at any rate, means should be provided to obviate the delay that now exists in providing adequate treatment for mental disorders. It is, therefore, recommended that psychiatric clinics should be established.”[80]

Again, at the International Congress of Medicine in London, in August, 1913, an important discussion of these problems was introduced by an account of the Henry Phipps Psychiatric Clinic which has been established in Baltimore for the treatment of mental disorders, and for teaching and research in this subject. In the course of the discussion special emphasis was laid upon “the necessity for _teaching the medical profession and the public_ that many mental disorders are absolutely recoverable, that good hospital and scientific treatment save many, that the mere economy of our monster institutions represents a sham economy paid for by the patients and their families, and that psychiatry must extend beyond the asylums.”[81]

Emphasis was also laid upon the importance of making these hospitals, for the care and cure of those suffering from mental illness, centres for scientific education and research and for the development of prophylactic measures. For, unless medical students are provided with facilities for the study of these early cases the present deplorable condition of affairs will be perpetuated. All honest medical work is essentially research; for every individual patient presents problems which need investigation; and facilities should be provided for making such enquiries under the most favourable conditions. As Dr. Flexner has well said,[82] it is impossible “to develop two types of physician, one to find things out, the other to apply what has been ascertained. For the same kind of intelligence, the same sorts of observation, knowledge and reasoning power are needed for the application as for the discovery of effective therapeutic procedure.”

This last consideration leads us to the examination of another potent factor in the present situation, _viz._:—

The Attitude of the Medical Profession. When it is remembered that mental factors play an important rôle in the causation and continuance not only of obviously mental disorder but also of bodily troubles, and that therefore successful diagnosis and treatment must inevitably take these factors into account, it may seem remarkable that the medical profession as a whole should take so little interest in, and know so little of psychology. Even when the psychological aspect of their problems becomes the outstanding element in diagnosis and treatment, the vast majority of medical practitioners show little or no inclination to satisfy their scientific curiosity and to endeavour to understand the condition of their patients.

But this attitude becomes more comprehensible, and in a certain measure more excusable, when we look into the courses of instruction provided for students in our medical schools. What training in psychiatry—to say nothing of psychology and psychopathology—have they received in the schools? How many hours have been spent in lectures or demonstrations upon

mental diseases? And how has this modicum of time been spent? How many hours are devoted to actual _personal investigation_ of patients suffering from early mental disorder? All the instruction in such matters that our students get at present in most of the medical schools is given in a few hours during one term, when they visit an asylum where demonstrations are given of _advanced_ cases of mental disease: “melancholia,” “mania,” “dementia,” etc.

Lest we may be accused of wild statements, let us quote again from the Medico-Psychological Association’s report. (The italics are ours.):—

“... the attention given to mental diseases before qualification is much less than that given in many other countries. Owing to the absence of clinics, the medical student _has no opportunity of observing borderland or undeveloped cases_.” (p. 6.)

“To this absence of teaching facilities is due the lack of knowledge of the general practitioner, who should be competent to recognise, and possibly to deal with, some of the earliest symptoms; _to this we owe the lack of real equipment in those who enter the lunacy service_.” (p. 21.)

In this connection it is interesting to quote from a comparatively recent report on medical education. Four years ago the Carnegie Foundation for the Advancement of Teaching published a report on “Medical Education in Europe.” This work was remarkable both for its perspicacity and thoroughness and for the frankness and detachment with which its author, Dr. Abraham Flexner, expressed the opinions he had formed after a detailed study of the medical schools of this country and on the Continent. This valuable and important document was barely noticed by the medical press in this country. But this is not the place for a discussion of the psychology of this conspiracy of silence. For it certainly does not imply any reflection upon the impartiality or the thoroughness of Dr. Flexner’s research; on the contrary, it is a silent tribute to the seriousness of the exposure of the weaknesses of our medical schools. But the report is also a most valuable appreciation of the strength of our methods of medical education. It provides a minute analysis and comparison of the methods of teaching clinical medicine in Great Britain and on the Continent. The summary clearly defines the distinctive merits of the British system, and has such an important bearing upon the questions we are considering in this book that we will quote its most essential paragraph.

“The limitations by which medical education in Great Britain is hampered have now been candidly exposed. It is nevertheless true that in respect to the student, nowhere else in the world are conditions so favourable. In our discussion of Germany we pointed out that its clinical instruction was overwhelmingly demonstrative; that the student _saw_ and _heard_ but almost never _did_. Clinical education in England has completely avoided this wasteful error. It is primarily practical. It makes, indeed, the huge mistake of assuming that a more scientific attitude towards the problems of disease is in some occult way hostile to practicality; for it protests against the adoption of modern methods of investigation, as though practical teaching would be in some inexplicable fashion endangered thereby. However, that may be, the English are indubitably correct in holding that sound medical training requires free contact of the student with the actual manifestations of disease. It is the merit of English and, as we shall also perceive, of French medical education that the student learns the principles of medicine concurrently with the upbuilding of a veritable sense-experience in the wards, and that he acquires the art of medicine by increasingly intimate and responsible participation in the ministrations of physician and surgeon. The great contribution of England and France to medical education is their unanswerable demonstration of the entire feasibility of the method of instruction which the end sought itself imposes.”[83]

We have quoted at length this vivid and accurate portrayal of the distinctive feature of British methods of clinical instruction in order to emphasise the fact that in the teaching of psychological medicine the British utterly neglect this excellent method of instruction which Dr. Flexner considered so admirable a feature of our medical schools. The British method of teaching psychological medicine, so far as the subject is taught at all,[84] is that of class-demonstration, but, as we have seen, the avoidance of exclusive reliance upon this method is the feature on which Dr. Flexner congratulates the British schools. On the other hand, while the Germans are criticised for their adherence to the class-demonstration, it should be remembered that, although this source of weakness appears in their undergraduate classes, it is they and not we who provide facilities, in their clinics, to the post-graduate student for free contact with patients in incipient stages of mental illness.

Therefore we have neglected to apply, in the case of mental diseases, the very methods which in all other branches of medicine have been so conspicuously successful as to be selected by an impartial critic as the distinctive merit of British medical training.

We have indicated briefly the type of instruction in psychiatry obtaining in our medical schools at present. Its educational value is certainly very slight; and—what is worse—it serves to give the future doctor a hopeless outlook on insanity. For the instruction of students in the nature and treatment of tuberculosis we do not send them to some sanatorium to gaze upon patients dying from the

disease. They personally examine patients in the early stages and learn to recognise the subtler manifestations of the onset of the tubercular attack, when there is some hope of giving useful advice and saving the sufferer. Why cannot mental disease be dealt with in the same way? Why cannot our students be afforded, in general hospitals, the opportunity of personally examining patients in the incipient stages of mental disturbance? They would then not only acquire a knowledge of the real nature of insanity, but would also learn, in the school of experience, the individual differences which are exhibited in the working of the normal mind, a lesson which would be of the utmost value to them in dealing with _all_ their patients, whether their ailments be bodily or mental. But in addition such a training would impress on them, in a way that nothing else could do, the vitally important fact that mental disease is curable, and is not the hopeless trouble which is likely to be suggested by the spectacle of a few asylum patients in advanced stages of lunacy.

Even, however, if the asylums afforded better facilities for the proper study of mental disease than unfortunately is the case in most institutions in this country, they are usually not sufficiently near the medical schools to permit the student properly to acquire his knowledge, as he does of other diseases, by frequent and regular attendance for a considerable period of time. Nor, as yet, have many of the medical officers in our asylums sufficient up-to-date knowledge of psychiatry to enable them usefully to co-operate with the medical schools and the teaching staffs of the general hospitals in achieving the desired aim. We know that there are some exceptions to this general statement, and fortunately they are becoming more numerous. But viewing the condition of affairs in the country as a whole, in respect of this important matter, one can only accurately describe it as deplorable. These are hard words, and we are well aware that their use may expose us to the charge of superficial, uninformed and even spiteful criticism. Let us, therefore, turn to the gratifyingly frank and honest statements of the asylum workers themselves, embodied in the report from which we have quoted.

“_The tendency of routine to kill enthusiasm and destroy medical interests._

The promotion or advancement of a medical officer depends so little upon his knowledge of psychiatry that he has no inducement for that reason to devote himself to an earnest study of the subject. His work is apt to begin and end with the discharge of essential routine duties to the exclusion of careful clinical and scientific investigation.

The work assigned to junior medical officers is, in the majority of cases, monotonous, uninteresting and without adequate responsibility. For those whose personal enthusiasm keeps alive in them the desire to extend their knowledge, such opportunities as that of study-leave are rarely afforded them. The existing system, therefore, leads to the stunting of ambition and a gradual loss of interest in scientific medicine. It tends, therefore, to produce a deteriorating effect upon those who remain long in the service.”[85] (pp. 8 and 9.)

Methods of Making Appointments.

“Appointments are made by lay committees, which, though they are generally wishful to appoint the best candidate, are in most cases without expert advice, and without adequate knowledge of the factors involved. The results are, therefore, generally haphazard in character, often dependent upon influence or personal consideration, as they frequently bear out little relation to the actual claims and qualifications of the candidate.” (p. 7.)

We submit then, that our expression of opinion is but a paraphrase of the authorised report. The study of this publication as a whole will only deepen this impression in the reader.

In the foregoing paragraphs we have pointed out the vital importance of research in relation to mental disease. All properly conducted clinical work is of the nature of original investigation; and in the examination of patients suffering from mental disturbance this is particularly the case. But a vast amount of research work must be carried out in properly equipped hospitals and laboratories if we are to deal with the problems of lunacy in the same efficient manner as we have learnt to treat tuberculosis. In this connection it is important to emphasise the lack of an adequate knowledge of normal psychology among many of the medical officers and the absence of psycho-pathological research in so many of our asylums.

It must not, however, be inferred that the only reform needed is an increase and improvement of the _mental_ treatment of mental disease. It is not merely the psychological side that is neglected. The most depressing aspect of the present state of affairs _is the comparative absence of all research_. Investigations into the material basis of mental disease, while certainly more numerous than psychological investigations, are at present few in number. Hosts of problems concerned with the nervous system are awaiting investigation, and the admirable results obtained by the small band of energetic workers in our country serve to show how sadly our

nation is neglecting its golden opportunities for accomplishing much more in this respect. Important problems in connection with the normal and morbid anatomy of the nervous system, its pathology and its bio-chemistry, suggest themselves to the worker at every step. The physiological and psychological effects of different diets, of drugs like the hypnotics, _et cetera_, how little we know of them! Are we to rest content in leaving this vast unknown land to be charted by other nations?

Original research is thus urgently needed in all those departments which should be included in asylum work. But it is also necessary for the researches to be co-ordinated. Not a few individual doctors in our asylums, usually members of the junior staffs, are endeavouring to carry on original investigations; but in the majority of cases the absence of any prospect of direct or indirect personal benefit from this work damps their enthusiasm, if it does not make such work wholly impossible. And, of course, without the willing co-operation of the asylum authorities co-ordinated researches cannot be carried out.

We shall again quote from the report of the Medico-Psychological Association in justification of our statement:—

“Research is largely dependent on individual enthusiasm, but can certainly be stimulated and maintained by the co-operation of the senior medical staff. There is reason to fear that such work is undertaken in some quarters without any guidance or encouragement from seniors, and laborious original investigations have received little or no recognition from those in authority.... Although there is no uniformity of practice, report is made that in many asylums junior medical officers are placed in charge of chronic cases only, and have no duties in reference to the treatment of newly-admitted cases. This appears to be most undesirable. Junior medical officers, in addition to their statutory routine duties, should be given the opportunity of co-operation with their senior colleagues in clinical work. Consultation between the various members of the medical staff in doubtful and interesting cases is very desirable....” (p. 30.)

If the reader will pause for a moment, and in imagination put himself in the position of a junior medical officer, “_placed in charge of chronic cases only_,” he will not only come to understand the “stunting of ambition and the gradual loss of interest in scientific medicine” of which he has read, but may admire the self-restraint of a report which can speak in temperate language of such a state of affairs.

Another difficulty that stands in the way of this urgently needed reform in medical education is the inadequacy of the text-books available for the student. In many of these text-books the introductory chapters contain some, often irrelevant,[86] morbid anatomy, and the remainder deals with “psychology.” The latter frequently consists largely of anecdotes, often “funny” and sometimes more appropriate to the “after-dinner” hour than the text-book, and enumerations of the mental _symptoms_ of the cases. In practically every available English text-book the latter are depicted only as they appear after they have become fixed, habitual, hardened and rationalised. Such “units” of terminology as “delusions,” or “delusions of persecution,” “hallucinations,” etc., are freely used. In other departments of clinical medicine the text-book writer does not describe a patient as suffering from a cough, and leave it at that; yet the phrase “suffering from delusions” is the veriest commonplace in the text-books. Yet just as a cough may be due to tuberculosis of the lung, pharyngeal irritation, hysteria, or a variety of utterly different causes, each class of case requiring a different treatment, so the causes of delusions are even more infinitely varied.

But the gravest defects of these text-books is that few of them make any attempt whatever, except in the case of such forms of disease as have an organic cause, to explain the _development_ of the trouble, the precise nature of the primary cause or causes and the way in which the disturbance of the patient’s personality has been gradually effected.

Unfortunately there are serious defects in many of the works upon general psychology which render them almost useless to the student of psychological medicine. This may explain, if it does not excuse, the quaint selection of subjects, often wholly irrelevant or inappropriate, which form the contents of the psychological section of many English books on mental disorders. But this deficiency is not a sufficient excuse for the neglect of the kind of instruction that is of vital importance for the proper understanding of such disorders. When books such as those written by McDougall, Stout, Hart, Shand, and Déjerine and Gauckler, are available, it is possible to use the facts of normal psychology as the natural, rational and necessary means of explaining and interpreting departures from the normal state.

We may summarise here some of the chief defects of our national system of treating mental disorder. First and foremost is the serious waste of time which almost invariably occurs before the mental sufferer comes under medical care. This is due to a variety of causes—all of them preventable. The chief is that, lying in the path of patients who would _voluntarily_ seek help, there is the insurmountable obstacle of the asylum system and its restrictions. The men in the asylum service, who have the opportunity of acquiring an intimate knowledge of mental diseases, are _forbidden_ to carry that knowledge into the outside world for the benefit

of the mental sufferer. If a patient, suffering from a mental disorder in its earliest and easily curable stage, should voluntarily go to an asylum and ask for advice, all that can be done for him is to suggest that he should consult a medical man outside, or to recommend him to call and see the relieving officer. Now, unless the patient has considerable means, it is practically certain that he will be able to consult no medical man who is conversant with—much less expert in—the treatment of early mental disorder. And, though the relieving officer's intentions may be of the best, it is just his 'help' and all that it means, that the unfortunate is so desperately striving to avoid. In short, all that the officials under our present system can say to such a man is, "Go away and get very much worse, and then we shall be allowed to look after you!" Can stupidity go farther than this?

Even, however, if the doctor were allowed to help such a person in the asylum, this would be far from an ideal solution of the difficulty. Entry into such an institution, even if voluntary, would entail the serious social stigma which has been so often mentioned. Furthermore, the asylum, with its associations and implications, particularly the assumption of the irresponsibility of the patients interned in it, would destroy one of the chief therapeutic agents in the treatment of such cases. We mean the conviction of the patient that he is still responsible for his actions, and that he is still able, under direction, to cure himself.

The place to which such a patient should be able to go is obviously one which is exempt from any stigma; one in which of his own free will he may stay for a time under care, or if this be unnecessary, as is very frequently the case, which he may visit at frequent intervals for advice and treatment. It should be staffed by skilled specialists who are familiar with the diagnosis and treatment of _early_ and _incipient_ mental disorder, not only with that of advanced insanity. For years such institutions have existed in other countries and form an important part of their contribution towards the alleviation of human suffering.

The chief functions of such a psychiatric clinic would be:—

(1) Attendance on the mentally sick.

(2) The provision of opportunities for personal intercourse between patients and the psychiatrists in training.

(3) The theoretical and practical instruction of students.

(4) Advising general practitioners and others who are faced with difficult problems arising in their daily work.

(5) To serve as a connecting link between investigation in the large asylums and that in the anatomical, pathological, bacteriological, bio-chemical, psychological and other laboratories of the universities.

(6) The scientific investigation of the mental and bodily factors concerned in mental disease.

(7) The furtherance of international exchange of scientific knowledge concerning mental disorder, by the welcome accorded to visitors from other countries.

(8) The dissemination of medical views on certain important social questions and the correction of existing prejudices concerning insanity.

(9) When necessary, the after-care of the discharged patient.

We have already given some details of the activities of a few of the clinics abroad[87] and have pointed out their valuable function in saving a high percentage of patients from the fate of an asylum, while at the same time relieving the community of the serious expense of keeping these patients for life as pauper lunatics.

We may quote from an article by Dr. R. G. Rows[88] describing the psychiatric clinics at Munich and Giessen:

"They are carried on upon the lines of 'freely come, freely go,' as far as is consistent with the safety of the patient and of the public. In neither of these clinics is any legal document necessary for the admission or discharge of patients. But where the character and severity of the mental disturbance require the longer detention of the patient in the clinic or in an asylum, such detention can be exercised only under a legal procedure which carefully safeguards the rights of the patients.

In this way it is possible to avoid the stigma which is attached to certification and seclusion in an asylum. That this is appreciated by the general public is demonstrated by the number of people who make use of the opportunities offered them. To the clinic at Giessen, with its seventy beds, between three and four hundred patients were admitted in 1907. From the report of the clinic at Munich for the years 1906-7 we learn that there were 1,600 admissions in 1905 (the first complete year after it was opened), 1,832 admissions in 1906, and 1,914 admissions in 1907. At the present time admissions go on at the rate of ten or twelve per day. It

should be mentioned that at Munich the clinic is open night and day for the reception of patients, so that they can be brought under the care of an expert at the earliest possible moment, and the painful impressions produced often by detention and restraint by unskilled persons and unsuitable surroundings are reduced to a minimum. This immediate treatment at the hands of men experienced in insanity is a matter of the greatest importance, from the point of view of a favourable termination of many of these cases.

Let us now consider the actual treatment of those admitted into these institutions. What most strongly impressed us in these clinics was the absence of noise and excitement amongst the patients; it was certainly an ample demonstration of the value of the means of treatment adopted. It is recognised in the first place that patients must not be crowded together: none of the wards contain more than ten beds.... For the patient who is too excited to be kept in bed or who disturbs the others too much, experience has shown that prolonged warm baths provide the best means of quieting him and bringing him into such a condition as will allow of his being kept in the ward. The extent to which the bath treatment is employed may be judged from the fact that besides the baths used for ordinary purposes of cleanliness there are in the clinic at Munich eighteen baths for prolonged treatment, five movable baths, one electric, and one douche bath. The wet pack is occasionally used. The baths are so arranged that the patient can remain in the bath for days or weeks as the case demands, sleep there and take his food there. The result of the treatment is that hypnotic drugs and confinement to a single room have come to be regarded as evils to be used only on rare occasions; in fact, the single rooms are occupied by convalescent and quite quiet patients and not by recent and acute cases.

Treatment on these lines will of course necessitate the employment of a large medical and nursing staff. At Giessen, with 70 beds and between three and four hundred admissions a year, there are five medical officers including the director. At Munich, with one hundred and twenty beds and three or four thousand admissions, there are fifteen medical officers to carry on the work of examination and supervision of the patients. The nursing staff must be provided in the proportion of at least one to five. This is of course a high figure, but there are two conditions to be remembered: first, the very large number of admissions dealt with, and secondly, that these clinics are established not for the housing of the insane, but for the care and cure of those suffering from incipient mental disturbances—a most important distinction, and one not yet fully appreciated in this country.

Besides the patients admitted into the clinics for treatment, a large number obtain advice and help from the out-patients' department."

It should be mentioned that in Germany there is a psychiatric clinic attached to every university.

Among the most important functions of a clinic are instruction and research. Each assistant in the Munich clinic carries on some chosen line of study. In order that he may have better facilities for becoming acquainted with the literature on the subject and finishing his selected work, he is given, besides his annual month's leave, two months of each year for this purpose. Frequent evenings are set apart for discussions of original work carried on in the clinic and elsewhere. Besides this, numerous short courses in special subjects are provided, so that it is possible to enter the clinic for instruction in matters requiring a special knowledge of delicate technique and diagnosis.

Of very special importance in the Munich clinic is the course for qualified medical men. In 1907 this was attended by _sixty men, of whom one third were foreigners_. What can we, in Great Britain, show in comparison with this? Our physical, chemical, physiological, and pathological laboratories attract distinguished foreigners from the universities of other countries, though twenty would be a number on which even our most celebrated laboratories would pride themselves. But how many foreigners come to us to study insanity? Very few indeed, and the reason is not far to seek.

In the Munich clinic, again, we find well equipped rooms for clinical examination, for the deeper investigation of mental life by experimental psychology, for the study of morbid anatomy and pathology and for the finer examination of the blood and other fluids of the body. Furthermore, these laboratories are not only spacious and well-equipped, but are occupied by busy, keen and skilled workers. Testimony to their activity is afforded in abundance by their frequent publications.

We submit, then, that the clinic system is a decided advance in the treatment of mental disorder which other countries have adopted while for years we have stood by with folded hands.[89] From the humanitarian and the scientific point of view there is everything to be said in favour of the clinic. The practical Englishman will, however, ask "What about the financial aspect? Are not these institutions, with their heavy proportion of doctors and nurses to patients, prohibitively expensive?"

The answer to this question is that certainly the clinic is relatively more expensive than the asylum. But since the function of the clinic is to save as many patients as possible from entering the asylum, it is obvious that its expense must be judged from a special standpoint. The maintenance of a repair shop is always comparatively costly, whether the material to be mended be human or not. The cost per day of repairing a motor car is usually distinctly higher than the daily charge for garaging it in its broken-down state. Yet we gladly pay the higher charge for the simple reasons that a motor car in its garage is of no use to us, and that the daily charge for housing the car would amount to a colossal figure if paid for many years. Cannot we apply the same reasoning to the case of the mentally disordered human being? This is to take the very lowest view of the value of the individual to the community. Yet it would seem that the British public, so far, has been impervious even to this financial consideration.

But, it may still be asked, cannot the doctors in the asylums carry out the work suggested? The answer to this is, that apart from the undesirability of allowing a patient suffering from a mild mental disorder to be associated with an institution housing the definitely insane, it is a physical impossibility for the asylum doctors to do this work so long as the present proportion of doctors to patients remains unchanged. How many members of the British public realise the fact that it is quite usual for an asylum doctor to be in charge of at least 400 patients, and that this number sometimes rises to 600? When it is remembered that insane patients are even more prone than the average person to suffer from physical ailments, and that their mental disorders are infinitely complicated by the delay incurred before they come under medical care, it becomes clear that the doctor who would succeed in treating such patients individually would require titanic energy and the addition of at least twenty-four more hours to each of his working days. We cannot therefore compare the staff of a clinic with that of a British asylum, for the staff of the latter is lamentably and obviously too small.

Regarding the financial aspect of the question we may quote again from Dr. Rows' article:—

"... we shall no doubt be met with the objection that the provision of such institutions will involve the expenditure of such an immense sum of money. I believe we spend in Great Britain about £3,000,000 a year on those suffering from various forms of mental affliction. That, certainly, is an immense sum to spend while getting so little in return. A large proportion of this money is spent in housing, feeding, clothing, and taking care of the 97,000 inmates of the county and borough asylums of England and Wales. We learn from the commissioners' report, published in 1910, that 20,000 patients were admitted into these asylums during the previous year, and of these, over 30 per cent. were discharged after a longer or shorter detention. Now it may safely be said that very few of these 20,000 fresh admissions did obtain, or could have obtained, any advice for their mental illness at the hands of anyone who had had experience of mental disorders, before they reached the stage when certification and seclusion in an asylum became necessary. When we visited Giessen we were informed by Professor Sommer that in the province of Hesse, by reason of suitable treatment during the early stages of mental illness they had been enabled to postpone for some years the erection of a new asylum in the province. Is it not therefore fair to assume that, if facilities were provided whereby expert advice and treatment in a well-organised psychiatric clinic could be obtained by those threatened with a mental breakdown, we should save enough of the £3,000,000 to justify the expenditure involved in the establishment of such clinics? Further benefits would be derived from them in that we should be able to avoid the breaking-up of the home, which now, in so many instances, follows the removal of the bread-winner of the family to an asylum and his long detention there."

And

"... it may be suggested that we should attempt to demonstrate the possibility of saving money in order to carry the public with us in the matter. I do not think that is necessary. The value of treatment of the early stages of mental disorder cannot be expressed in pounds, shillings and pence. Moreover, I submit that our duty as medical men is to guarantee the satisfactory treatment of the patient, and we have no right to allow our action to be dominated by monetary considerations. I feel sure that the more this question is placed before the public in an intelligent manner, the more we insist upon the necessity for early treatment and for scientific knowledge as a basis of any treatment, the less will the public grumble about expense. We have ourselves to thank if the public refers so constantly to money matters. Do we ever encourage the public to regard the question from any other point of view? Do we point out that insanity is a product of civilisation? Do we encourage people to regard insanity as an illness for which something can be done and which should be treated with intelligent and humane consideration? Do we not rather say with the public, "Lock him up, put him where he can neither harm himself nor his neighbour?" Do we not talk of sterilising the unfortunate sufferers and preventing marriage and procreation before we have made an honest effort to investigate what insanity really is, what is the mechanism of its production, and how we can teach those so afflicted to help themselves? How then can we expect the public to do anything but grumble at the expense? The public has not objected to spend money in other branches of medicine when the necessity has been demonstrated, and there is no reason, if the members of the lunacy service in this country will develop

confidence in themselves, why they should not be able to instil confidence into those outside the profession."

Suggested Reforms. After the depressing picture of the present state of affairs in this country it will be asked, "What should be done to remedy it?" The answer to this question is clear and definite.

For the relief of the mentally afflicted amongst us, and especially for the prevention of insanity, it is our bounden duty as a nation to take measures such as most civilised countries have adopted some time ago. For this purpose it is necessary that there should be hospitals to which patients in the early stages of mental disturbance can go, without any legal formalities, and receive proper treatment from physicians competent to diagnose their troubles and to give them appropriate advice. It is important that such special hospitals should be attached to general hospitals, so that sensitive patients may not be deterred from resorting to them by the fear of the stigma which in this country, unfortunately, is so inseparably linked with the idea of a "lunatic asylum." It is also important that such institutions should be affiliated to medical schools, not merely to ensure the adequate education of the coming generations of medical practitioners, but also to afford the staffs of such hospitals the proper opportunities for carrying on the work of investigation which is essential for the success of the scheme we have sketched out.

No less important and urgent a reform than the foregoing, however, is another consideration—the _legal_ aspect of the treatment of the mentally deranged.

The glaring defects of the present system have been well and briefly pointed out by Dr. Bedford Pierce in his article from which we have quoted, published in the _British Medical Journal_ of January 8th, 1916.

Again, Sir George Savage, writing in Allbutt's _System of Medicine_ (Vol. VIII, p. 429) states:—

"The lunacy legislation of this country, despite the Acts of 1890 and 1891, remains in an unsettled state; and the care and treatment of the insane are burdened with vexations and unnecessary restrictions. Not only are the steps required for the placing of a person of unsound mind under legal care complicated and clumsy, but they result in many cases in a delay of that early treatment which is so important in cases of mental disease."

Dr. F. W. Mott writes:—

"There is yet one point which it is desirable to mention, as the result of both hospital and asylum experience, and that is the necessity of some earnest attempt being made to establish a means of intercepting, for hospital treatment, such cases of incipient and acute insanity as are not yet certifiable. It is probable that many would not come into the asylums, and a certain number of cases thus come under observation willingly, and in time to retard the progress of the disease. Practitioners could send doubtful cases for observation and treatment to such hospitals, where, moreover, the opportunity would be afforded of improving their own knowledge as to the early signs of insanity."[90]

He urges the desirability of the establishment of special wards in connection with general hospitals, pointing out that a mental case coming from such a ward would not thereby be stigmatised as insane. He quotes from 'an American writer on psychiatry':—"Fortunate would be the community in which there was a fully equipped and well-organised psychiatrical clinic under the control of a university and dedicated to the solution of such problems. The mere existence of such an institution would indicate that people were as much interested in endeavouring to increase the public sanity as they are in the results of exploration in the uttermost parts of the earth, or in the discovery of a new star."[91]

The Medico-Psychological Association's report says:—

"The lunacy law does not permit of the establishment of clinics on the lines which have been recommended, nor does it provide for the admission of uncertified cases to the public asylums. This, for the present at any rate, renders nugatory the suggested schemes for affording treatment for incipient and non-confirmed cases of mental disorder, and with that, to a large extent, fail the opportunities for study on which stress has been laid for adding to the knowledge and increasing the efficiency of asylum medical officers." (p. 10.)

Such weighty opinions as these serve to emphasise a further factor in the urgently needed reform—the necessity for a thorough overhauling of the law of lunacy, so that, while guarding the liberty of the subject, every obstacle should be removed that obstructs patients threatened with the dire calamity of insanity from securing preventive treatment at the earliest possible moment.

In the _Lancet_ of August 5th, 1916, Dr. L. A. Weatherley writes:—

“The great fact that must be continually brought forward in all these discussions is that, according to the reports of the Commissioners in Lunacy, the _recovery-rate of mental diseases is to-day no higher than it was in the ‘seventies’ of last century_. The ever-increasing difficulty in getting mental cases with small means quickly under skilled care must, I feel sure, account to a great extent for this lamentable fact.”

“Marking time” since the seventies of the last century—how does this condition compare with that of most of the other branches of medical science? Heart disease, diphtheria, tuberculosis, tetanus, sepsis of all kinds, all these troubles and many others have shown unmistakable signs of yielding to the incessant and many-sided assaults of medical research. And, of insanity, all we have to report in this country is “little or no progress for fifty years.” Verily we have buried our talent deep in the ground.

Finally, we may quote from an article the opening sentences of which might have been written yesterday, yet it was published in 1849! It was the fourth report of the visiting committee of Hanwell Asylum. The committee say:—

“In the constitution of the Hanwell Asylum we are also struck by the paucity of the medical officers attached to it. There appear in round numbers to be about 500 patients on the male and 500 on the female side, yet there is only one resident medical officer attached to each department, and one visiting physician for the whole establishment. The inefficiency of so small a medical staff is obvious. If we look across the Channel we find in Paris that the Salpêtrière, with its thousand patients, has four times the number of visiting physicians and ten times the number of resident medical officers. The disproportion between the sane and the insane is here so great that it is impossible under such a system to bring any moral influence to bear upon the afflicted multitude.”

“... There ought to be a more numerous medical staff _and a permanent clinic_ attached to such an institution.... The County Asylum of Hanwell, supported largely as it is by county rates and parish assessments, is as much a hospital as St. George’s or St. Bartholomew’s, and ought to have a medical staff as numerous and efficient as those of any other metropolitan hospitals. While charity might thus be administered upon the highest principles of Christian benevolence, something ought to be done to advance our knowledge of science and thereby enable us to relieve the afflictions of suffering humanity.”

The dust lies thick upon this volume, published a short time before the _Crimean_, not the present war. And to-day, like this early Victorian committee, we still ask for clinics, we still ask for scientific work to be carried out by a more numerous and better equipped staff, we still look across the Channel with admiration—in short, approving the better, we follow the worse. We have dawdled away half-a-century and more in comparative idleness. Now the war has taught us our lesson. Are we to forget it again?

Excuses for inertia, brought forward before August, 1914, can be accepted no longer. The thousands of cases of shell-shock which have been seen in our hospitals since that time have proved, beyond any possibility of doubt, that the early treatment of mental disorder is successful from the humanitarian, medical and financial standpoints. It is for us, not for our children, to act in the light of this great lesson.

FOOTNOTES:

[74] p. 105.

[75] It should not be forgotten, however, that resort is often made to alcohol as an easy means of drowning the worry of an incessant mental conflict. In other words, it is clear that in treating alcoholism, as in treating insanity, we are not absolved from the plain duty of seeking its mental cause or causes. “Drink” then, in many cases, appears rather as a secondary complication than as a primary factor.

[76] _Cf._ W. Aldren Turner, _op. cit._

[77] One of the most gratifying of these is the generous gift of a clinic to London by Dr. Henry Maudsley. Up to the present this institution has been rendering valuable service to the country as part of the 4th London General Military Hospital.

[83] p. 202.

[84] “... at present we have few facilities for teaching the subject, and the subject is not taught.” (_Medico-Psychological Association’s Report_, p. 20.)

[85] Concerning this sentence the _British Medical Journal_ wrote, on Nov. 29th, 1914, “A more severe indictment of the existing system than is contained in this report it would be difficult to frame.... We can add nothing to this strongly worded condemnation except an expression of agreement with the opinion that the statement of the facts submitted demands the earnest attention of public authorities and all interested in the welfare of the insane.”

[86] Irrelevant because such books give an account of the morbid anatomy of the nervous system only as it presents itself after disease of very long duration.

[87] pp. 82 _et seq._

[88] “The Development of Psychiatric Science as a Branch of Public Health,” _Journal of Mental Science_, January, 1912.

[89] The gratifying establishment of the Maudsley clinic and the provision of facilities for out-patient treatment at a few hospitals in England and Scotland are signs that matters are at last improving. But we are sure that the physicians in charge of such out-patient departments would be the first to admit their inadequacy and to urge the desirability of the psychiatrical clinic of the kind described in this book.

WHOSE APPRECIATION OF THE HARMONIES OF ART, AND WHOSE HIGH IDEALS OF ARCHITECTURE HAVE FOUND EXPRESSION IN MANY ENDURING FORMS, THIS BOOK IS RESPECTFULLY INSCRIBED.

[Illustration: Decoration]

PREFACE

The temptation to wander, with all the recklessness of an amateur, into the traditions of the best architecture, which necessarily could be found only in the history of early Hellenic art, awakened in the author a desire to ascertain who were the individual artists primarily responsible for those architectural standards, which have been accepted without rival since their creation. The search led to some surprise when it was found how little was known or recorded of them, and how great appeared to be the indifference in which they were held by nearly all the writers upon ancient art, as well as by their contemporary historians and biographers. The author therefore has gone into the field of history, tradition and fable, with a basket on his arm, as it were, to cull some of the rare and obscure flowers of this artistic family, dropping into the basket also such facts directly or indirectly associated with the architects of ancient Greece, or their art, as interested him personally. The basket is here set down, containing, if nothing more, at least a brief allusion to no less than eighty-two architects of antiquity. The fact is perfectly appreciated that many fine specimens may have been overlooked; that scant justice has been done those gathered, and that the basket is far too small to contain all that so rich a field could offer.

This book, therefore, aims at nothing more than a superficial glance at the subject, and the author will be content if he has accomplished anything toward bringing those great geniuses of a noble art into a little modern light, who have been left very much to themselves in one of the gloomiest chambers of a deep obscurity.

CHAPTER I.

THE POPULAR APPRECIATION OF ARCHITECTS.

Of all the fine arts none more completely answers for its _raison d’être_ than architecture. In this art alone do we find the harmonious mingling of æsthetical fancy with utilitarian purpose. It is this feature of usefulness that completes its well-rounded perfection, rather than detracts from it, and dignifies its mission of existence. Architecture, in its capacity to draw to its enrichment the other arts, may be compared to the polished orator, whose purpose is to sway the judgment of his audience by forensic effort, embellishing his language with the flowers of rhetoric, adapting his gestures to graceful emphasis, and controlling his voice to suit the light and shade of his thought. So sculpture has been stimulated by architecture and has contributed to its ornamentation; painting has been invoked to the highest accomplishments, and music has awakened within its walls voice and harmony. “The progress of other arts depends on that of architecture,” Sir William Chambers very truly says. “When building is encouraged, painting, sculpture, gardening and all other decorative arts flourish of course, and these have an influence on manufactures, even to the minutest mechanic productions; for design is of universal advantage, and stamps a value on the most trifling performance.”

It is perhaps not a little odd that despite its pre-eminent importance, and the high rank which it has ever assumed, from that early time when the first rays of dawning civilization began to warm the latent germs of culture and refinement in human nature, to the present day, it is the only art that has not, with very rare and isolated exceptions, stamped renown upon those who have practised it as a profession, and lifted the artist into the lasting remembrance and gratitude of the admirers of his works. How greatly the painter, the sculptor, the musician, are identified with their arts, and the products of their brush, chisel or pen! how great has been their praise, how lasting and unstinted the esteem in which they have been held! but how reserved has been the applause that has encouraged the architect who has given to the world the grand and noble results of his skill and genius, and how soon he himself has been forgotten! It happens only too often that it is the name of the distinguished painter that stamps the value of his canvas rather than the merits of the picture itself. The title of a beautiful piece of sculptured marble is not asked with greater eagerness than that of the artist who created it. Bach and Beethoven and Mozart are played and sung to the popular audiences rather than their fugues, their sonatas and their symphonies.

But what is known of the artists who have reared the greatest monuments of enduring architecture? Their personality, and even their names, appear to have faded from popular recollection. This seems to have been the fact from the earliest days of the art in Greece and Rome to the present time. The exceptions are so rare, throughout all the intervening ages, and the waving prominence of the art, that they might almost be numbered upon the fingers of a single hand.

The reader, if he is not a professional architect, or an amateur who has read deeply in his favorite subject, can arrive at the truth of this seemingly exaggerated statement, if he will lay aside this book for a moment and try to recall the names of the designers of some of the more conspicuous monuments of architecture he has visited at home or abroad.

“I will erect such a building, but I will hang it up in the air,” exclaimed Michael Angelo when he saw the dome of the Pantheon at Rome. The reader may remember this boast of the great Renaissance genius, the fulfilment of it in the colossal dome of St. Peter’s, and be satisfied that his memory has captured one architect of celebrity. If the beautiful Florentine campanile of Giotto looms up in his recollection he will think at once also of that early artist, but perhaps not more so in connection with that ornate tower than in association with the Pre-Raphaelites. Of course, he will not overlook Inigo Jones, whose very name is stamped upon the memory

by reason of its peculiarity, or Sir Christopher Wren, the creator of St. Paul's, and the British idol. If he is an admirer of the picturesque architecture of Venetian churches and palaces, the Italian Palladio may not escape him; and if of French Renaissance, the Louvre façade will possibly suggest Perrault, and the Parisian roofs Mansard. If he is a native of our "Modern Athens," of course, the peril in which the classic front of the State House rested for a time, at the hands of a _fin de siècle_ legislature, will not permit him to forget Bulfinch, and Trinity Church will bring to memory the only Richardson. But aside from a few names such as have been mentioned, with possibly a sprinkling of others fixed in the memory, by incident or association, the average reader, however well acquainted he may be with the numerous luminaries of the other arts, will be unable to say who was responsible for the beauty and nobility of many buildings that have individualized the cities and towns of their location to the art-loving world. Who, for example, can tell of the authors of the cathedrals at Milan and Siena, Cologne and Strassburg, Rheims and Amiens, Wells and Litchfield; the Giralda at Seville; the Church of the Invalides at Paris; the Strozzi Palace at Florence; the Henry VII. chapel at Westminster Abbey; the much and justly admired south façade of the old City Hall in New York; Grace Church in that city; the Capitol building in Washington, or that model of colonial architecture in America, the Executive Mansion?

It is not, however, the purpose to here speculate too extensively upon the apparent lack of justice on the part of the general public which has been done the architects of all climes and times, but to gather together a few facts concerning the Old Masters of early Grecian architecture that are not popularly known, and recall some of the leading lights of that art so inimitably practised by the Hellenic people during their progress from archaic darkness to the zenith of their æsthetic culture.

It is but repeating a well-worn truth to say that the influence of the early Grecian architects upon the followers of their art in all countries of recognized civilized enlightenment, throughout the ages that have succeeded them, has been an almost dominant one. Robert Adam, the architectural authority in the time of George III., says, in the introduction to his work on the ruins of the palace of the Emperor Diocletian: "The buildings of the ancients are in architecture what the works of nature are with respect to the other arts: they serve as models which we should imitate and as standards by which we ought to judge; for this reason they who aim at eminence, either in the knowledge or practice of architecture, find it necessary to view with their own eyes the works of the ancients which remain, that they may catch from them those ideas of grandeur and beauty which nothing, perhaps, but such an observation can suggest."

It is equally true that no country that has experienced an evolution in intelligence and culture, during the twenty-five hundred years that have fled since the time of Pericles, has succeeded in introducing any new school of architecture, that has not been compelled to draw upon ancient Greece for many of the most important and essential features of the art it could only modify, but never wholly re-create.

The Gothic, or pointed-arch style, that sprung into such beautiful being in the thirteenth century, and reigned a queen within the Christian countries of Europe for several centuries thereafter, came more nearly answering for an original scheme of architecture than perhaps any other of equal importance, and yet had it been deprived of the Grecian props that helped to sustain it, it must have fallen to the ground.

In the Gothic the effort was made to incline the inherited principles of architecture more closely toward the spiritual progress of the people, but when at last it had run its course, and was dethroned, owing to a realization of the fact that even a closer allegiance to classic models could be made to answer still better spiritual requirements, how completely did the artistic temperament of the people revert to Greece and Rome, as the light of their returning inspiration and truth appeared with the dawn of the sixteenth century. Renaissance architecture and Renaissance art swept Europe like a wave, and the people turned with reactionary enthusiasm to the ancient standards of art, as they did to the study of classic authors, and to the writing of even Greek and Latin verses.

The debt of gratitude, therefore, which posterity has owed the originators in ancient Greece of the three noble orders of architecture—namely, the Doric, Ionic and Corinthian—can scarcely be overestimated, for it is to those three orders or styles that all subsequent architects have turned for the fundamental truths of their art. They may not have followed each or all with conventional strictness; but they have not succeeded in escaping from borrowing many of the features there everlastingly fixed by the unerring geniuses of classic times.

"Famous Greece! That source of art, and cultivated thought, Which they to Rome, and Romans hither brought."

The uses to which the Greek and Roman architectural forms, principles and ornaments have been put since the birth of the Renaissance have broadened largely, and would seem to preclude any possibility of their ever again falling into even partial

desuetude. It is not only in the more pretentious buildings, monuments and ornamental structures that abound so plentifully in the populous and wealthy cities that classic models and features are so liberally employed, but even the unpretentious and simple rural homes cannot escape their use. What is more common than the Doric mutule or Corinthian modillion, so frequently seen in the cornices of modern houses, or the Ionic dentils that show their teeth below a piazza roof or over the door casing of a colonial dwelling? The various combinations of the fret, the egg and dart, the bead and fillet, the honeysuckle, the acanthus and many other Grecian _motifs_ of ornamentation, are met with constantly, not only in buildings of a public or private nature, but in furniture and fresco, in interior decoration, and in enhancing the attractiveness of almost any article of use or ornament. Even the simple ogee moulding, which is employed, if nowhere else, about the door panels of the humblest abode, is classic in its origin, and had its archetype in the entablatures of those stately and beautiful temples dedicated to the pagan gods of ancient Greece.

It must not be inferred, however, that all the individual features employed in the Greek orders found their birth in the brains of Hellenic architects. Sir Jeremy Bentham says:

“From Egypt arts their progress made to Greece, Wrapt in the fable of the Golden Fleece.”

This statement, however, though poetical, is much too sweeping to be literally correct as to architecture. The Greeks borrowed a little—a very little—not only from the Egyptians, but from the Assyrians, the Chaldeans, the Persians, and other western Asiatic races as well; but so altered what they had borrowed, so refined it and entwined it with original conceptions of their own, that the captive features could have returned again to their native lands without fear of detection. Indeed as to the origin of some of the architectural features which the Greeks are supposed to have taken from the countries of a more unrefined people to the south and east of them, and especially as to the volute, so conspicuous in the Ionic capital, which is supposed to have been a Persian conception, there is much dispute.

Professor T. Roger Smith, of London, very truly observes: “We cannot put a finger upon any feature of Egyptian, Assyrian or Persian architecture the influence of which has survived to the present day, except such as were adopted by the Greeks. On the other hand, there is no feature, no ornament, nor even any principle of design which the Greek architects employed that can be said to have now become obsolete.”

In discussing the three primary orders of which mention has been made, and to which he adds the Tuscan and Composite, both of Italian or Roman origin, and closely dependent upon the original three, Sir William Chambers remarks: “The ingenuity of man has hitherto not been able to produce a sixth order, though large premiums have been offered, and numerous attempts been made by men of first-rate talents, to accomplish it. Such is the fettered human imagination, such the scanty store of its ideas, that Doric, Ionic and Corinthian have ever floated uppermost, and all that has been produced amounts to nothing more than different arrangements and combinations of their parts, with some trifling deviations scarcely deserving notice; the whole tending generally more to diminish than to increase the beauty of the ancient orders.... The suppression of parts of the ancient orders, with a view to produce novelty, has of late years been practised among us with full as little success; and although it is not wished to restrain sallies of imagination, nor to discourage genius from attempting to invent, yet it is apprehended that attempts to alter the primary forms invented by the ancients, and established by the concurring approbation of many ages, must ever be attended with dangerous consequences, must always be difficult, and seldom, if ever, successful.” Thus is seen the marvellous discretion and judgment exercised by the Grecian architects in selecting from contemporary art that alone which was best to perpetuate, and thus is well expressed in the statement of indisputable fact, a tribute to their originality and creative genius.

And who were these Old Masters of classic architecture—older in point of service to their art by thousands of years than Giotto and Raphael and Michael Angelo and Inigo Jones and Sir Christopher Wren, and many others who might be mentioned, and who in campanile and cathedral, in public building and private palace, in monument and mausoleum, have proved themselves justly entitled to the laurels with which they have been crowned, but who nevertheless are but disciples of Hellenic and Roman masters? Where do we find the biographies of the original Old Masters of architecture recorded? Where can we turn to read of their lives, of their deeds and achievements, of their aspirations and ambitions, of their shortcomings and their foibles? Where are written down those anecdotes and incidents of personal interest, so entertaining in association with their works or their art? What, in fact, were their names? There is comparatively little recorded of the lives of the Greek and Roman architects with which to answer these questions; strange as it may appear, even their names are unfamiliar, and in many important instances are forgotten altogether. Among that large galaxy of brilliant men which Greece in her prime produced, who figured prominently in almost every walk of life, who were great in war and in peace, in philosophy and poetry, in satire and history, in oratory and valor, and as great, if not greater than in all, in statuary and sculpture—a galaxy clinging to the memory in all ages of human progress, because never excelled, the

name of a Grecian architect is a strange sound, and does not ring in tune, if it is ever heard at all, with the names enrolled upon the list of Greek immortals.

The sculptors and statuaries of ancient Greece are especially well remembered in the popular mind, and Myron and Phidias and Praxiteles and Polycletus call for no introduction to the ordinarily informed lover of art; not so the designer of the Parthenon or the Temple of Theseus, or the Erechtheum, or the Choragic monument of Lysicrates. It is strange that the artist who modelled or chiselled a bull or a cow or a Faun or a nude Venus, or any pagan god or goddess, however much we may praise the excellence of his skill, should be remembered by posterity, while the artist, his contemporary, who designed the most beautiful and graceful buildings of all time, which in their glory were the pride of their people, and which in their decay and ruin are still the loadstones that attract pilgrims from the most distant lands, is forgotten, and, it would appear, denied almost the humblest mention. Can it not be said of the Grecian architects, as well as the Grecian sculptors, that under the magic of their touch “Stones leap’d to form, and rocks began to live”? Were not the temples they reared in all the pride of surpassing beauty, which tempted the sculptor’s caress on frieze and pediment, and which gave shelter to those works of the statuary’s art which Shakespeare recalls so vividly when he draws the simile:

“They spake not a word. But, like dumb statues, or unbreathing stones, Stared at each other, and look’d deadly pale,”

as much entitled to give immortality to their creators as the works, however competitive, of other branches of art to their authors? And still so incidentally and indifferently have the historians and biographers of their time alluded to the Grecian architects, that little or nothing is to be found to quench that desire to know of them personally, which an interest in their grand achievements may well awaken.

Did we not know it to be otherwise, we might think that they, too, were like the poor architect of whom Goethe speaks: “He is employed in lavishing all the luxury of his fancy upon halls from which he is to be ever excluded, and display his ingenuity in bestowing the utmost convenience upon apartments he must not enjoy.” But it does not appear that any social discrimination was exercised against the Greek architects to cast a shadow upon their present or future fame.

It is popularly believed that the great buildings of the ancient world were very long in the process of construction—that they, in fact, took many decades and sometimes even hundreds of years to complete. If this were true it might in a measure explain the obscurity in which their architects have been left, inasmuch as the original designer of the building might have been forgotten ere the last of his successors had finished the work he had undertaken. But this is not altogether the fact. Even the pyramid of Cheops—that colossal marvel of the creative genius of man—we are informed by some authorities took but thirty years to construct, ten of which were given to the building of a road leading to the site of the pyramid, for the greater facility in handling the huge blocks of stone to be used. Neither were the temples and public edifices of Greece and Rome, as a rule, long in building, being generally undertaken and finished during the influential period of a public man’s career, or the reign of a single emperor. There were, of course, exceptions to this rule, as, for example, the temple of Apollo at Delphi, that erected to Diana at Ephesus, and that dedicated to Jupiter at Athens; but in nearly all such instances it will be found that the temples were destroyed and rebuilt during the long interval which is supposed to have passed from the time when their foundations were first laid, to that which found them again in all respects completed structures; or, if not destroyed and the work undertaken anew, the delay was caused by some political influence which contributed to check the continuous prosecution of the work, implying no procrastination on the part of the original builders. But even in the most of such cases the names of the various architects who were from time to time associated with the work are at least known, if their biographies are not more fully recorded.

It may be stated broadly that both the Greeks and the Romans were rapid builders when the size of their edifices is taken into account. Especially is this true of the time of Pericles, if we are to believe the testimony of Plutarch: “Every architect strived to surpass the magnificence of design with the elegance of execution, yet still the most wonderful circumstance was the expedition with which they [the buildings] were completed. Many edifices, each of which seemed to require the labor of successive ages, were finished during the administration of one prosperous man.” And the great biographer also adds: “... Hence we have the more reason to wonder that the structures raised by Pericles should be built in so short a time, and yet built for ages, for each of them as soon as finished had the venerable air of antiquity; so now they are old they have the freshness of a modern building. A bloom is diffused over them which preserves their aspect untarnished by time, as if they were animated by a spirit of perpetual youth and unfading elegance.”

Another mistaken idea is that the sculptors of ancient times were also architects. Some instances occur where, like the Italian, Michael Angelo, a prominent sculptor of Greece or Rome, made architecture one of his accomplishments, but they were not as numerous as they are supposed to have been, and the rule seems to be the reverse: that the sculptors of antiquity had no technical knowledge of architecture, and that the arts were quite as distinctly practised as professions in early times as they are to-day.

There remains to be presented only one other reason for the indifference shown the early architects by their contemporary writers and public, which is so well expressed by an English historian in his discussion of the Coliseum at Rome, that it may well be quoted as a type of the excuse offered by apologists of the same class: “The name of the architect to whom the great work of the Coliseum was entrusted has not come down to us.[1] The ancients seem themselves to have regarded this name as a matter of little interest; nor in fact do they generally care to specify the authorship of their most illustrious buildings. The reason is obvious. The forms of ancient art in this department were almost wholly conventional, and the limits of design within which they were executed gave little room for the display of original taste and special character.... It is only in periods of eclecticism and Renaissance, when the taste of the architect has wider scope and may lead the eye instead of following it, that interest attaches to his personal merit. Thus it is that the Coliseum, the most conspicuous type of Roman civilization, the monument which divides the admiration of strangers in modern Rome with St. Peter’s itself, is nameless and parentless, while every stage in the construction of the great Christian temple, the creation of a modern revival, is appropriated with jealous care to its special claimants.” In other words, the pupil is a fitter artist to awaken the personal interest of those who admire his works than his master; and the revived imitation of more consequence to the public than the original model. If this were true, why should the Coliseum, “the most conspicuous type of Roman civilization,” upon which the pilgrims of the North, as we are informed by Gibbon, based the longevity of Rome itself, when in their rude enthusiasm they gave expression to the proverb, “As long as the Coliseum stands, Rome shall stand; when the Coliseum falls, Rome will fall; when Rome falls, the world will fall,” _divide_ the admiration of the stranger with St. Peter’s? Should it not, rather, be subordinate to the Christian cathedral of Bramante, Raphael and Michael Angelo? Is there not a touch of the _reductio ad absurdum_ in this argument? Such reasoning does not seem to be quite obvious upon other grounds as well. If it is the fact that the ancients regarded the names of their architects as of little interest, and their buildings as wholly conventional, why does Vitruvius speak of four of the principal temples of Greece as “having raised their architects to the summit of renown”? Why is it that Rhœcus and Theodorus, Ictinus, Mnesicles, Dinocrates, Detrianus, Apollodorus and many other architects—to whom more particular mention will be made later—are remembered in ancient history with more or less circumstantiality, not only in association with their works—all conventional, if we are to accept this writer’s judgment—but also on account of their individual merit, while the architects of the buildings which departed most from that same conventionality, both in plan and detail, as, for example, the Erechtheum, the original Odeon of Pericles and even the Coliseum itself, where:

“Firm Doric pillars formed the solid base, The fair Corinthian crown the higher space, And all below is strength, and all above is grace,”

are lost in the ocean of oblivion?

Do not our modern authors overlook the fact that the architects of their own age share, as a rule, in the same popular indifference, and that the period of revival is no exception to the period of inception; that the one has inherited from the other not only the forms and principles of its art, but the same neglect of its artists?

Whether this is true or not, the fact must remain and be accepted with patience or impatience, as we please, that there is little preserved for us by the ancient writers in respect to their architects. Two rather conspicuous exceptions, however, occur to this general rule in respect to Pausanias, the Lydian, and Vitruvius Pollio, the Roman.

Pausanias lived toward the close of the second century after Christ. He was a great traveller and a close observer, his observations having been confined principally to works of art, such as public buildings, temples and statues, which he mentions in direct and simple language. He visited most of the states of Greece at a time when that country was still rich in her treasures of art, and what he has to say of what he saw there would tend to indicate that while he was by no means a critic or a connoisseur, he was still a faithful and minute recorder of what appealed to his taste or excited his curiosity.

Vitruvius, however, was not only a writer on architecture, but a professional architect as well, who resided in Rome about a century earlier than Pausanias, or in the time of Augustus. He is practically the only writer of his time who has given us technical information concerning the ancient buildings. Vitruvius wrote his treatises upon architecture at a very advanced age, and, it would appear, much in defence of the pure Greek models which were even in that time being corrupted. The frankness with which he hopes for

fame by reason of his book, and exposes his poverty as well as the unprofessional practices of his brother architects, is not the least attractive feature of his discourse: “But I, Cæsar,” he exclaims, “have not sought to amass wealth by the practice of my art, having been contented with a small fortune and reputation, than desirous of abundance accompanied by a want of reputation. It is true I have acquired but little, yet I still hope, by this publication, to become known to posterity. Neither is it wonderful that I am known to but few. Other architects canvass and go about soliciting employment, but my preceptors instilled into me a sense of the propriety of being requested and not of requesting to be entrusted, inasmuch the ingenuous man will blush and feel shame in asking a favour; for the givers of a favour, and not the receivers, are courted. What must he suspect who is solicited by another to be entrusted with the expenditure of his money, but that it is done for the sake of gain and emolument? Hence, the ancients entrusted their works to those architects only who were of good family, and well brought up, thinking it better to trust the modest than the bold and arrogant man. These artists only instructed their own children or relations, having regard to their integrity, so that property might be safely committed to their charge. When, therefore, I see this noble science in the hands of the unlearned and unskilful of men, not only ignorant of architecture, but of everything relative to buildings, I cannot blame proprietors who, relying on their own intelligence, are their own architects; since, if the business is to be conducted by the unskilful, there is at least more satisfaction in laying out money at one’s own pleasure rather than at that of another person.”

Vitruvius also epitomized in his books on architecture much that had been written prior to his time by his professional brethren of Greece and Rome, and so preserved something of what otherwise might have been entirely lost.

Allusion has been made to these two writers with some particularity, for the reason that they will be more quoted than any others in the course of this volume, but it must not be inferred that they are alone responsible for all the knowledge which has come down to us respecting the Greek and Roman architects, little and unsatisfactory as it is.

Although it has been shown that the historians and biographers of ancient Greece made no attempt to treat architects with especial favor, it would not be just, however, to close this chapter without quoting from Homer to prove that lie, at least, could rank them as among those who, by serving the people in the highest sense, were entitled to unusual hospitality:

“... What man goes ever forth To bid a stranger to his house, unless The stranger be of those whose office is To serve the people, be he seer, or leech, Or architect, or poet heaven-inspired, Whose song is gladly heard?...”

FOOTNOTES:

[1] There is an old ecclesiastical tradition, which is much doubted, that the architect of the Coliseum was a Christian by the name of Gaudentius, who suffered martyrdom in its arena, and that the services of thousands of Jews contributed to its erection.

CHAPTER II.

THE MYTHICAL AND ARCHAIC ARCHITECTS AND BUILDERS.

History does not probe so deeply into the earliest annals of the races that inhabited the Peloponnesian peninsula, that it does not show them to have been pre-eminent as builders; nor does it follow the ancient Greek people throughout the long ages that spanned their evolution and decadence, that it does not find them in all the stages through which they passed, leaving at least some of their walls, temples or monuments to resist the ravages of all time, and the decaying influences of the elements. They built, therefore, not only well, but perhaps better than they knew, and have proved that if the creations of their intellects were immortal, as we know, the works of their hands were not altogether perishable.

The Pelasgic tribes, who were the first of which there is any record to have inhabited Greece, were great wall-builders, and past-masters of defensive architecture in those early ages. Although we may not have the names of the individual architects among them, we have their racial works still before us to evidence the fact that whoever the architects were, they knew their business eminently well. The Acropolis at Athens possesses the finest example that remains of Pelasgic mural work, in the fortified retaining wall which surrounds it, and which is sometimes called after the race that built it, the Pelasgicum.

It is claimed also by some authorities that the Pelasgi were the original architects and builders of the “Long Walls” that connected Athens with her seaport gates, and of such parts of the peribolus as were not the authentic work of the builders under Themistocles and Cimon, and subsequent architects to be hereafter mentioned.

The Cyclopes, who belonged to Pelasgic times, were likewise remarkable wall-builders, lending their name to a kind of mural work in a manner original with them, and having the attributes of great solidity and endurance. The ruins of houses and other structures erected by them have been found also at Tiryus and Mycenæ, on the plain of Argos.

Speaking of the circuit wall at Tiryus, Pausanias describes it as being “composed of unwrought stones, each of which is so large that a team of mules cannot even shake the smallest one;” and of Mycenæ, the more important city, a short distance from Tiryus, where the circular treasury of Atreus and other evidences of Cyclopean architecture have been excavated by Dr. Henry Schliemann, Euripides asks the question: “Do you call the city of Perseus the handiwork of the Cyclopes?”

Modern archæologists are inclined to the opinion that the Cyclopean builders were not, as originally supposed, the one-eyed giants whom Ulysses encountered in his voyages, as related in the Homeric legends, but an entirely distinct Thracian tribe, which derived its name from king Cyclops. After being expelled from Thrace, where were their early homes, they migrated to Crete and Lycia; thence following the fortunes of Prœtus, and giving him protection with the gigantic walls which they constructed as against Acrisius, his twin brother, who was very quarrelsome, as twin brothers not often are.

These Cyclopean walls, which are still to be found throughout Greece, as already stated, and also in some parts of Italy, were made of huge, uncut polygonous stones, sometimes twenty or thirty feet wide, piled upon each other without cement, frequently irregularly, with smaller stones filling up the interstices, but occasionally in regular horizontal rows. There were, in fact, not only several kinds of these walls, but several eras in which they were built as well.

It is not, however, the intention here to discuss the nature and extent of the Pelasgic and Cyclopean constructions, it being sufficient to recall the fact that so far as the Pelasgians generally are concerned, they were not only the progenitors of most of the early architectural monuments of eastern Europe, but were skilled in the arts and learned in the fables of the gods as well, bequeathing both religious rites and many arts to their children, the Greeks. It remains only to add, also, that so closely were they identified with the art of building that it is believed their very name is derived from their leading pursuit, for it is thought that the term Pelasgi may be interpreted to mean “stone-builders” or “stone-workers.”

In this allusion to the Pelasgians as builders, it was stated at the outset that the names of the individual architects among them are not known; this was perhaps unfair to Æacus, if he can be ranked as an architect, and who is classed as a Pelasgian, although of divine parentage.

Æacus was a son of Jupiter by Ægina, daughter of the river god, Asopus, and, like the Cyclopeans, he was particularly expert in the matter of walls. He was as well a very just and pious individual or myth, who was frequently called upon to hold the scales of justice, not only as between mortals, but also immortals. He was born on the Island of Ægina, the temporary residence of his mother, after whom it was named. At the time of his birth the island was uninhabited. This very unpleasant condition of isolation for the mother and son was quickly remedied by Jupiter, who changed the ants that abounded there into men, placing Æacus over them as king.

Æacus always kept on the very best of terms with the gods, propitiating them in many ways, and at last becoming a great favorite with them. Indeed, so strong was his influence in celestial circles that at one time when Greece was afflicted with a drought, in consequence of a murder that had been committed, the Delphic oracle declared that the only person who could help the situation at all was Æacus. He was accordingly appealed to and persuaded to petition the gods for relief. The result was that his petition was favorably answered. Æacus thereupon erected a temple to Zeus Panhellenius on Mount Panhellenion to show his gratitude, and possibly to keep himself in that position where he might trespass upon the good-nature of his heavenly friends again at some future time, should there be necessity.

Æacus surrounded his island with high walls to protect his people against pirates. It is probable that these walls attracted the admiration of Apollo and Neptune, and prompted them to retain the professional services of their builder to assist them in erecting the walls of Troy. But here it was that Æacus failed, for as one diamond can only be accurately judged when placed in comparison with another diamond, so Æacus, however successful he may have been as a wall-builder by himself, was outclassed when he came into competition with the occult knowledge of Apollo and Neptune.

The story is that when the Trojan walls were completed, three dragons appeared and rushed upon them to test their strength. The two dragons which attacked those parts of the walls built by the celestial associates of Æacus had their heads broken for their pains, but the one which flew at the mortal’s share of the work made a hole in the wall which let it into the city. Apollo at once

prophesied that Troy would eventually fall through the hands of the Æacids, which prophecy, of course, proved true. Whether this failure had anything to do with the future of Æacus or not, it would be difficult to say, but the fact is that after his death he became one of the three judges in Hades, with special jurisdiction over the Europeans, which necessarily insured his being overworked until the end of time.

With a people possessed of so large and varied an assortment of deities, suited to every possible human need and shade of mortal endeavor, it would be strange indeed if there was not some mythical or legendary character among the Greek gods to preside over architecture, if not as a distinct art, at all events in association with some of its kindred branches. That the Greeks did not ignore such a necessity is found to have been the case, and the great Dædalus rises most admirably to the occasion in personifying the early infancy of architecture as well as sculpture and wood-carving.

Dædalus, like most of his spiritual relations and associates, led a life of much romance and adventure, not unmixed with hardship and trial. He was either a native Athenian or Cretan, a point upon which there is some dispute, as well as upon another involving his parentage. It is perhaps sufficient to know that Dædalus flourished in the age of Minos and Theseus, and was introduced more or less into the legends pertaining to those two early characters.

It is upon Dædalus that responsibility must rest for the first introduction of jealousy into the personality of artists, a vice, by the way, which they have never been quite able to shake off from his time to the present. Dædalus was rather sorely afflicted with this unfortunate trait, and to its early exhibition is due much of his subsequent misfortune. It was in connection with his devotion to sculpture that his jealousy first involved him in trouble. He became very expert as a carver generally, and undertook to instruct his nephew Perdix in the art. In due time and under the careful tutorage of his uncle, Perdix also became proficient, and in a moment of inspiration is said to have invented that very useful tool of the mechanic, the saw. This it was that excited Dædalus, who, in a fit of jealous rage, threw his nephew over the Pelasgic walls of the Acropolis, killing him instantly as he supposed.

Dædalus was, of course, condemned to death for this unseemly and cruel manifestation of envy, but managed to escape and fly to Crete. There his professional reputation had preceded him, and he obtained the friendship of king Minos. In Crete he developed his latent architectural skill, and built a very elaborate and intricate dwelling for the hideous monster Minotaur, since known as the celebrated labyrinth at Cnossus. The story of how Theseus, with the connivance of Ariadne, the charming daughter of Minos, slew this monster, is one of the most thrilling of the mythological legends, and is quite familiar.

Just how Dædalus incurred the displeasure of Minos does not seem to be very clearly stated by the early authorities. It appears that he was in some way entangled with the creation of a wooden cow, also with Pasiphaë, the wife of Minos, and even with the birth of the horrible Minotaur. Possibly it may have been Minos who this time became jealous. However that may be, the friendship which had existed between Dædalus and the king finally became strained, and the former was compelled to fly the country, which he did in a very literal way, as king Minos had seized all the ships on the coast of the island, cutting off, in consequence, the only means of escape. The architect, however, possessed much ingenuity and inventive genius of his own, even to a more marked degree than that manifested by the nephew he had dropped over the Athenian precipice, and with the aid of some feathers, a little wax, and Pasiphaë, who secretly contributed her assistance, he manufactured a pair of wings for himself, and another pair for his son, Icarus, who was with him at the time. Thus it will be seen that the first flying machines were invented by an architect.

[Illustration: THE FLIGHT OF DÆDALUS AND ICARUS.]

When the father and son started for Sicily, over the Ægean sea, like a pair of huge birds, Dædalus flew conservatively and cautiously, being careful not to rise too near the sun, where it was supposed by the ancients to be very hot; but Icarus, with the spirit of youth and the enjoyment of the exhilaration consequent upon the novelty of his method of locomotion, gave a deaf ear to the protests of his father, and, in emulation of Apollo, soared so high that the sun melted the wax in his wings. His feathers flew off, and down he dropped into the waves below. He was drowned, and that part of the Ægean sea into which he fell was afterward called the Icarian sea, in commemoration of this unfortunate accident, which Darwin has so well described in verse:

“... With melting wax and loosened strings, Sunk hapless Icarus on unfaithful wings; Headlong he rushed through the affrighted air, With limbs distorted and dishevelled hair; His scattered plumage danced upon the wave, And sorrowing Nereids decked his watery grave. O’er his pale corse their pearly sea-flowers shed, And strewed with crimson moss his marble bed; Struck in their coral towers the passing bell, And wide in ocean tolled his echoing knell.”

Dædalus, who could not stop to rescue his son, continued steadily on his course, and, attempting no experiments with his frail wings, finally landed safely in Sicily, where he established himself again, professionally, under the royal patronage of Cocalus, king of the Sicani. Here he did most excellent work, until king Minos, his old enemy, found him out, and began to make it unpleasant for him again. Minos, hearing that Dædalus was in Sicily, sailed with a great fleet to that island, but fortunately for the architect, his enemy was murdered as soon as he arrived there by Cocalus or his daughter. In the mean time Dædalus, anticipating the trouble that was in store for him, again made an escape, this time to Sardinia, where he tarried a while, but finally visited other countries, notably Egypt.

These are the substantial facts of Dædalus's career, as contained in the earlier legends, but later Greek writers tell a much more fanciful and improbable story of his life, which there is no urgent necessity to believe, as the one mentioned is quite fanciful enough and probably more authentic. They say, among other things, that Dædalus was an astrologer, and that he taught his son that science, who, soaring above plain truths, lost his wits and was drowned in an abyss of difficulties.

Dædalus may have been an astrologer and may have been other things as well, but that he was an architect cannot be doubted from the fact that so many buildings are ascribed to him. Among his works may be mentioned the Colymbethra, or reservoir in Sicily, from which the river Alabon flowed into the sea; another an impregnable city near Agrigentum, in which was the royal palace of Cocalus; still another a cave in the territory of Selinus, in which the vapor arising from a subterranean fire was received in such a way as to answer for a vapor bath. He enlarged the summit of Mount Eryx for a foundation for the temple of Venus, and he is said to have been the author of the temples of Apollo at Capua and Cumæ, and the temple of Artemis Britomartis in Crete. In Egypt he was the architect of a very beautiful propylæum, or vestibule to the temple of Hephæstus at Memphis, for which he was rewarded by being permitted to erect in it a statue of himself, the work of his own hands.

As a sculptor he also executed many works of art—but the architectural side of his career can only be considered here. It will not be out of place, however, to mention some of the inventions ascribed to him to assist the mechanic. It is claimed for him that he was an expert carpenter, having been taught that trade by Minerva, and that he originated the axe, the plumb-line, the auger and glue.

Dædalus, in fact, seems to have personified the earliest Grecian art, and his name, which, when translated, signifies "ingenious," or "inventive," stands for that period in Greece when form and shape and expression were given inanimate substances by the use of tools and mechanical appliances.

When Dædalus threw his nephew over the high walls of the Acropolis, and naturally thought that he had killed him—an opinion in which it is apparent the people of Athens shared—he was very much mistaken, for Minerva, the patron goddess of the city, realizing what a great mistake it would be to allow so bright and promising a young man to go to an early death, exercised her magic, and saved him by changing the falling artisan into a bird, which was given his name, "Perdix," or, as translated, Partridge.

To Perdix, who was especially skilful as a worker in wood, is attributed, in addition to the invention of the saw, suggested to him by the backbone of a fish or the teeth of a serpent, it would be difficult to say which, the chisel, the compasses and the potter's wheel. Whether he invented any of these things after he became a partridge or not is another mythical uncertainty, but probably not, as his changed condition and feathers would have made it very awkward for him to have done so, although most anything was possible in those days.

Perdix is also called Talos by some writers, and Pausanias mentions him by still another name, Calos, and states that after his death he was buried somewhere on the road leading from the theatre in Athens to the Acropolis.

It might be interesting, but certainly a task beyond the scope of this book, to mention all the mythical personages of the archaic or early period of Grecian art, who were in a way more or less remote, responsible for special features of artistic treatment that graced the buildings of that time, such, for instance, as Dibutades, who was the first to make masks on the edges of gutter tiles. Dibutades was a sculptor, and the idea which he originated is said to have been suggested to him by seeing his daughter trace the lines of her lover's profile around the shadow which it cast upon a wall. He filled in the lines with clay, and, moulding it to the face, gave to the world the art of modelling.

Among the artists belonging to the Dædalien, or legendary period of Greece, who may be classed more distinctively as architects, however, were Polycritus, who had to do with the building of the town of Tanagra by Poemander, and Pteras, who was supposed to have been the architect of the second temple to Apollo at Delphi. The legend is that the first temple was made of branches of the wild laurel from Tempe, and that Pteras constructed the second of wax and bees' wings—rather an unsubstantial building material,

it might be inferred. Eucheir, a painter, and Chersiphron and Smilis, architects and statuaries, are also of this traditional period, and were representative of skill in their arts.

All these names, however, although supposed to have been originally purely mythological, were probably later assumed by or given to mortals who were specially expert in the particular branch of art which the name taken suggested. These individuals, to complicate matters, no doubt, became entangled with the early mythological stories, and finally lost their identity completely, or to such an extent as to make it quite impossible to separate the fact from the fiction in their respective cases.

An illustration of such a confusion is to be found in respect to the architects, Rhœcus and Theodorus, who had to do with the building of the temple of Hera at Samos, for the worship of which goddess Samos was celebrated, and who, in association with Smilis, were the architects of the labyrinth at Lemnos.

The writers who have mentioned these artists are quite numerous, and have so differed in respect to their dates, and confounded the accounts of their careers and achievements, that it is difficult to sift anything like a satisfactory story from the confusion created. The most probable deduction that has been made, however, is that Rhœcus flourished about 640 B.C., and was a son of Phileas of Samos; that Theodorus, the architect, was his son, and that another Theodorus, a statuary, sometimes mistaken for the architect, was a nephew of the architect Theodorus, the son of Telecles, also a gifted sculptor, and a grandson of Rhœcus.

The temple of Hera, alluded to as the work of the father and son, was three hundred and forty-four feet long by one hundred and sixty feet wide, and, according to the “Antiquities of Ionia,” a decastyle, dipteral structure, or possessed of a double row of columns composed of ten columns in each row. Pausanias thinks that the temple was of very great antiquity, a fact apparent to him from the statue of Hera which it contained, which was made by Smilis, of wood, as were the early statues of Greece.

The Lemnian labyrinth, according to Pliny, contained fifty columns and innumerable statues, and had very remarkable massive gates, so delicately poised that a child might open or shut them. Modern travellers have had difficulty in finding any trace of this labyrinth, although there is little doubt that it once existed. It is not to be classed with the more visionary labyrinth in which the Minotaur was caged.

It is claimed for both Rhœcus and Theodorus that they were the first to invent the art of casting statues in bronze or iron, but as this art was known before their time by the Phœnicians, it is likely that they were responsible for nothing more than having introduced it into Greece. This is probably true also of other early mythical characters of Greece, to whom is attributed certain inventions in the arts which have been found since to have existed much earlier than their time in Egypt or elsewhere.

Theodorus is also credited with having been the architect of the old Scias at Sparta, and of having advised the use of charcoal beneath the foundation of the temple dedicated to Artemis, at Ephesus, as a remedy against the dampness of the site. Theodorus was a great admirer of his father and of the temple to Hera, which they built together. He attested his appreciation of the latter by writing a book descriptive of it.

As for Smilis, who belongs to the mythical period, and whose name when translated stands for “a knife for carving wood,” or “a sculptor’s chisel,” he is also accredited with having been the first to devise the art of modelling in clay. He is to be classed more as a sculptor than an architect, but of an inferior standing to Dædalus. In fact, his only connection with architecture, according to Pliny, seems to have been his association with Rhœcus and Theodorus in the building of the labyrinth at Lemnos. It is possible that even here he was employed more in the line of a sculptor than in lending any professional assistance as an architect.

Pausanias mentions a pupil of Theodorus of Samos, who, it would appear, achieved considerable distinction both as an architect and sculptor, but more especially in the latter capacity. His name is given as Gitiadas, and his birthplace as Lacedæmon, where he flourished about 724 B.C., as stated by some authorities, but much later according to others. The architectural work for which he receives credit was the temple of Athena Polionchos at Sparta, which, it is said, was constructed entirely of bronze. It also contained a bronze statue of the goddess of Gitiadas’s own workmanship, and many bas-reliefs representing the labors of Hercules, the exploits of the Tyndarids, Hephæstus releasing his mother from her chains, the Nymphs arming Perseus for the expedition against Medusa, and other mythological subjects, all executed in the same metal. This extensive use of bronze suggested the name “Brazen House,” which was given the temple. It would seem that Gitiadas was possessed of other accomplishments, and served Minerva with equal distinction as a poet, writing his poems all in the Doric dialect.

A still stranger _compôte_ of fact and fable, of hypothesis and conjecture, of celestial and terrestrial biography, is to be found in the accounts of the brothers Agamedes and Trophonius, who were the architects of the great temple of Apollo at Delphi, and of the

treasury of Hyrieus, king of Hyria in Bœotia.

The temple to the beautiful and accomplished son of Jupiter and Latona, the god of music and prophecy, as well as other things of equal or less consequence, was the fourth to be erected upon the same site on Mount Parnassus, in the ancient city of Delphi, known to the older poets as Pytho, a name derived from the serpent Python which Apollo slew. In this temple, which was the first of the four to be built with stone, the others having been constructed out of the branches of the bay tree and other equally perishable materials, dwelt the much respected and frequently consulted Delphic Oracle. The spot in the temple from which the prophetic vapor issued to inspire the priestess with second sight was said to be the central point of the earth, and that where the two eagles despatched by Jupiter to ascertain that point met and fell.

Pythia, the priestess of Apollo, who gave mouth to the oracles, sat on a sacred tripod placed over the opening from which the vapor issued, and gave forth her words of wisdom in prose or poetry as the occasion demanded. If in prose, her prognostications would be immediately verified, and if in verse some time must elapse before they could be fulfilled. Pythia was not always on duty, but could be consulted only on certain days during the month of Busius in the spring.

There is no doubt but that she made some very remarkable prophecies, but, alas! it is also recorded that, like some of the political oracles of these degenerate times, her prophetic vision was not infrequently influenced by “a previous interview.” A notable case of this kind was that in which the Alemæonidæ were entangled; who for political reasons and effect rebuilt the same temple after it was destroyed by fire in the year 548 B.C., as we shall see later.

But we have drifted from the subject. It is claimed by some that Agamedes was the son of Stymphalus, who was murdered and had his body cut up in pieces, and a grandson of the old ancestor of the Arcadian Arcas, who in turn was a son of Zeus. Others say that the father of Agamedes was Apollo, and his mother was Epicaste, and still others are of the opinion that his parents were none other than Zeus himself and Iocaste, another name for Epicaste, and that Trophonius was his son. All this genealogy is, however, disturbed if we accept the more probable one, that he was a son of Erginus, king of Orchomenus, and that he was a brother of Trophonius. By the way, Trophonius is also said to have been a son of Apollo. When these two young men attained to manhood they became very expert in the art of building temples to the gods and palaces for kings. Thus having established enviable reputations in their profession, they were retained to plan and supervise the works mentioned.

It is in respect to these architects that the first authentic account of a misunderstanding as to professional compensation is related. It must not be thought that because some of the early architects were related to the nobility of Mount Olympus, they were any the less mercenary than are architects in our own time, or were any more inclined to work for nothing than are their professional descendants of to-day.

Plutarch tells us that Agamedes and Trophonius, after working hard upon the Delphic temple, and not receiving any pay, began to lose faith in the mortals who were backing the undertaking. As they grew more and more dubious about their compensation, and possibly having notes or bills to meet, they finally decided to appeal directly to Apollo, in whose glorification the shrine had been built.

Apollo, who was consulted through the Delphic Oracle, informed them that he must have time to think the matter over. In other words, he could not be hurried in his decision, but would give them an answer at the end of seven days. It is not unlikely that the Oracle saw an occasion here where it might be a matter of financial prudence to consult with the other side before rendering a decision. However that may be, the two architects were told that Apollo wished that they should spend the intervening time in “festive indulgence.” Thinking from this, quite naturally, that they were in the good graces of the god, and suspecting no ungodly duplicity, Agamedes and Trophonius set about to enjoy themselves according to the most liberal interpretation of their instructions. The result was that at the end of the seventh day they were found dead in their beds, whether from too much festivity on their part or too much duplicity on the part of the Oracle, no one knows, but the inference is conclusive that as they were dead it was not necessary to give them the professional compensation they had been so anxiously demanding.

Cicero tells the story a little differently, and eliminates the question of compensation from it. He says that they consulted Apollo to know what in his opinion was “best for man”? This being a much easier question to handle, Apollo took but three days to answer it, but the consequences of the consultation to poor Agamedes and Trophonius were quite as disastrous. It may be that, taking everything into consideration, it is best for man to be dead, but most architects don’t think so, and had Agamedes and Trophonius anticipated such an answer, it is probable that they would have asked no questions.

Pausanias relates an altogether different legend and connects it with the treasury of Hyrieus, which Agamedes and Trophonius built, instead of with the temple of Apollo. The story by Pausanias would tend to show that these architects were even more mercenary than Plutarch has given us to understand they were.

It seems that in constructing the treasury they contrived to have a stone so placed that it could be taken away from the outside of the building at any time, and thus offer an entrance to the vaults. No one of course had any knowledge of this secret entrance but themselves. In consequence, after the building was finished, and it was used for the purpose for which it was intended, these two covetous brothers carried away from time to time goodly portions of the treasure as it was deposited. The king soon heard that there was a leak in his treasury, and that he was losing money rapidly. He was naturally annoyed and much perplexed when he found that the locks and seals of his treasure house remained intact and uninjured. He thereupon set a trap to catch the thief. Just what kind of a trap it was is not explained, but after some little time Agamedes was caught, and Trophonius, finding his brother ensnared, cut off his head, to save his own, doubtless, and prevent the discovery of his association in the robbery. This very unfraternal act of Trophonius was not allowed to go unpunished, however, and Apollo, or some other god, caused him to be swallowed up in the grove of Lebadea.

Pausanias further states that Erginus, the father of Agamedes, was known as the “Protector of Labor,” that Trophonius was called the “Nourisher,” and that Agamedes had the reputation of being the “Very Prudent One.” There can be no doubt about Agamedes’s prudence, such as it was.

Trophonius, it appears, had a still further career after his death, as an oracle, conducting his business from the spot where he was swallowed up in Lebadea. He was especially prophetic in matters relating to futurity. Those desiring to consult him were conducted to a cavern, and furnished with a ladder, by means of which they could descend into it. They were then given the information for which they were in quest, either by means of their eyes, or their ears, or such of their senses as the occasion seemed best to suggest. Some say that one of these visitors, after having gone into the cave, and being treated in this way by the oracle, returned never to smile again; but Pausanias contradicts the story.

There is another belief in regard to these architects which must be simply alluded to. It is that Agamedes and Trophonius were deities of the Pelasgian times; that Trophonius was a giver of food from the bosom of the earth, and for that reason was worshipped in a cavern, and that Agamedes was not the wretched thief of Pausanias, but, on the contrary, a very generous character, who gave liberally from underground granaries.

A parallel to the story of the robbery of the treasury of Hyrieus by Agamedes and Trophonius is told by Herodotus in respect to the two sons of the builder of the treasury of the Egyptian king Rhampsinitus. These two young men, it seems, were also caught, while pilfering, in a trap, described with great circumstantiality by the “Father of History.”

CHAPTER III.

THE ORIGINATORS OF THE THREE ORDERS.

Who were the originators of the three great and primary orders of Grecian architecture is still a question which the discussion of the legendary and mythical architects, which has been briefly entered into, has not answered. It may be assumed inferentially that as the earliest of the Greek temples which have been referred to as the works of the progeny of the gods were in the Doric style, the pagan deities of Greece may claim some share of credit for having introduced that noble design to the world. The Ionic and Corinthian styles, however, are still to be accounted for, and as there is good ground to assume that they made their advent into architectural art at much later dates no celestial origin can be claimed for them.

Vitruvius, in relating his account of the origin of all three orders, alludes more directly to the birth of the Doric, and tells a story so picturesque and entertaining of the other two that although recognizing how well it may be known to the professional architect, it is difficult to resist the temptation to give it here entire:

“Dorus, the son of Hellen, and the nymph Orseis, reigned over the whole of Achaia and Peloponnesus, and built at Argos, an ancient city, on a spot sacred to Juno, a temple which happened to be of this order. After this many temples similar to it sprung up in the other parts of Achaia, though the proportions which should be preserved in it were not as yet settled.

“But afterward when the Athenians, by the advice of the Delphic Oracle in a general assembly of the different states of Greece, sent over into Asia thirteen colonies at once, and appointed a governor or leader to each, reserving the chief command for Ion, the son

of Xuthus and Creusa, whom the Delphic Apollo had acknowledged as son, that person led them over into Asia, and occupied the borders of Caria, and there built the great cities of Ephesus, Miletus, Myus (which was long since destroyed by inundation, and its sacred rites and suffrages transferred by the Ionians to the inhabitants of Miletus), Priene, Samos, Teos, Colophon, Chios, Erythræ, Phocæa, Clazomenæ, Lebedos and Melite. The last, as a punishment for the arrogance of its citizens, was detached from the other states in a war levied pursuant to the directions of a general council; and in its place, as a mark of favor toward King Attalus and Arsinoë, the city of Smyrna was admitted into the number of Ionian states, which received the appellation of Ionian from their leader Ion, after the Carians and Lelegæ had been driven out.

“In this country, allotting different spots for sacred purposes, they began to erect temples, the first of which was dedicated to Apollo Panionios, and resembled that which they had seen in Achaia, and they gave it the name of Doric, because they had first seen that species in the cities of Doria. As they wished to erect this temple with columns, and had not a knowledge of the proper proportions of them, nor knew the way in which they ought to be constructed, so as at the same time to be both fit to carry the superincumbent weight and to produce a beautiful effect, they measured a man’s foot, and, finding its length the sixth part of his height, they gave the column a similar proportion—that is, they made its height, including the capital, six times the thickness of the shaft, measured at the base. Thus the Doric order obtained its proportion, its strength, and its beauty from the human figure.

“Under similar notions they afterward built the temple of Diana, but in that, seeking a new proportion, they used the female figure as the standard; and for the purpose of producing a more lofty effect they first made it eight times its thickness in height. Under it they placed a base, after the manner of a shoe to the foot; they also added volutes to its capital, like graceful, curling hair, on each side, and the front they ornamented with cymatia and festoons in the place of hair. On the shafts they sunk channels, which bear a resemblance to the folds of a matronal garment. Thus two orders were invented, one of a masculine character, without ornament, the other bearing a character which resembled the delicacy, ornament and proportion of a female.

“The successors of these people, improving in taste, and preferring a more slender proportion, assigned seven diameters to the height of the Doric column and eight and a half to the Ionic. That species, of which the Ionians were the inventors, has received the appellation of Ionic.

[Illustration: THE ORIGIN OF THE CORINTHIAN CAPITAL.]

“The third species, which is called Corinthian, resembles in its character the graceful and elegant appearance of a virgin, in whom, from her tender age, the limbs are of a more delicate form, and whose ornaments should be unobtrusive. The invention of the capital of this order is said to be founded on the following occurrence: A Corinthian virgin, of a marriageable age, fell a victim to a violent disorder. After her interment her nurse, collecting in a basket those articles to which she had shown a partiality when alive, carried them to her tomb, and placed a tile on the basket for the longer preservation of its contents. The basket was accidentally placed on the root of an acanthus plant, which, pressed by the weight, shot forth, toward spring, its stems and large foliage, and in the course of its growth reached the angles of the tile, and thus formed volutes at the extremities. Callimachus, who for his great ingenuity and taste was called by the Athenians Catetechnos, happening at this time to pass by the tomb, observed the basket and the delicacy of the foliage which surrounded it. Pleased with the form and novelty of the combination, he constructed from the hint thus afforded columns of this species in the country about Corinth.”

The comments of Sir Henry Wotton in his “Elements of Architecture,” written in England during the latter part of the sixteenth century, upon this legendary account of the source of the three orders given by Vitruvius, are sufficiently attractive and quaint in language and spelling to warrant their being quoted also:

“The Dorique order is the gravest that hath been received into civil use, preserving in comparison of those that follow a more _masculine aspect_ and little trimmer than the Tuscan that went before, save a sober garnishment now and then of _lions’ heads_ in the _cornice_ and of _triglyph_ and _metopes_ always in the _frize_.... To discern him will be a piece rather of good _heraldry_ than of _architecture_, for he is knowne by his place when he is in company and by the peculiar ornament of his _frize_, before mentioned, when he is alone.... The _Ionique order_ doth represent a kind of feminine slenderness; yet, saith Vitruvius, not like a housewife, but in a decent dressing hath much of the _matrone_.... Best known by his trimmings for the bodie of this _columne_ is perpetually _chaneled_, like a thick-pleighted gowne. The _capitall_, dressed on each side, not much unlike women’s wires, in a spiral wreathing, which they call the _Ionian voluta_.... The _Corinthian_ is a columne lasciviously decked like a courtezan, and therefore in much participating (as all inventions do) of the place where they were first born, Corinth having beene, without controversie, one of the wantonest towns in the world.”

As for the Composite order, which, as has been already stated, is but a mixture of the Ionic and Corinthian, it would seem that Sir Henry has very little patience. He says with a contempt which he makes little effort to conceal: “The last is the _compounded order_, his _name_ being a briefe of his _nature_: for his pillar is nothing in effect but a _medlie_, or an _amasse_ of all the preceding _ornaments_, making a new kinde of stealth, and though the most richly tricked, yet the poorest in this, that he is a borrower of his beautie.”

There are those who in relentless search for truth at the expense of sentiment and poetry would spoil the pretty story which Vitruvius tells of the invention of the Corinthian capital by claiming for Egypt the distinction of being the mother-country of the order, and ascribing to that form of the Egyptian capital that bells out toward the abacus, and which is surrounded by open lotus leaves, as the archetype of the last of the three Grecian orders. There is, however, more probability to the story of Callimachus than there is similarity between the Egyptian and Corinthian capitals, in our opinion.

If we accept Callimachus as the originator of the Corinthian, although there does not appear any name of an architect to receive the individual credit for the invention of the Doric order, we may as well accept the deduction which Vitruvius draws in respect to Hermogenes, an Ionian architect, who is said to have flourished about 600 B.C., and credit him at the same time with being the first to introduce the feminine proportions and attributes into his art, and with having perfected, if he did not originate, the queenly Ionic order.

“When Hermogenes was employed to erect the temple of Bacchus at Teos,” says Vitruvius, “the marble was prepared for one in the Doric style; but the architect changed his mind, from the idea that other proportions, afterward called Ionic, were more suitable for the purpose, almost inducing the inference that Hermogenes was the inventor of those delicate proportions; he appears unquestionably to have displayed great skill and ingenuity in all his designs, and to have entertained the opinion that sacred buildings should not be constructed with Doric proportions, as they obliged the adoption of false and incongruous arrangements.”

Another fact which Vitruvius does not touch upon might tend to point to Hermogenes as the originator of the Ionic order. He was a native of Alabanda in Caria, and if it is true, as some authorities believe, the volute was an ornament in early use in Asia Minor, he was doubtless familiar with it; and, appreciating its graceful possibilities, introduced it into the matronly Ionic.

Hermogenes is conceded to have been one of the most celebrated architects of antiquity. In addition to the temple of Bacchus which he designed for Teos, one of the eastern Ionian cities, and the birthplace of Anacreon, as well as other noted ancient characters, he erected in the city of Magnesia, in Lydia, a temple to Diana in the Doric order. About each of these temples he wrote a book, both of which were still in existence in the time of Augustus. In one he described the temple to Diana as a pseudodipteral, or false dipteral temple, a form which he invented. It is called false or imperfect because of the economy of the inside row of columns on each of the long sides of the cell, the outside row being allowed to remain. The effect from a distance was the same as a double row, while considerable expense was saved. The temple to Bacchus he described as a monopterus, or a round temple, having neither walls nor cell, but merely a roof sustained by columns.

Hermogenes’s great ambition appears to have been a desire to foster and encourage the use of the Ionic order in preference to the Doric for temple construction. In this opinion he was later sustained by Tarchesius, another writer on architecture, who may be dated as sometime later than 470 B.C., and by Pytheus, whom we shall meet again as one of the architects of the tomb of Mausolus.

Although Vitruvius mentions the origin of the Corinthian order in close connection with that of the Doric and Ionic, it must be borne in mind that Callimachus, whom he credits with the Corinthian, was a much later artist than Hermogenes. The use of the Corinthian column by the architect Scopas in the temple of Athene at Tegea in 396 B.C., has led to the inference that Callimachus must have lived prior to that date, and the fact that he gave to that style of architecture the appellation of Corinthian, that he was a native of Corinth. Lübke, in his “Outlines of the History of Art,” however, does not give to Callimachus the full and undisputed credit for originating the Corinthian style, claiming that the order existed before his time, although he does not mention when or where. Lübke would interpret the story of Callimachus and the basket as meaning that it was he who gave to the capital its final perfection. It is somewhat strange also that although Callimachus is conceded to have been the first to develop this order, if he did not absolutely invent it, there is no mention of any building having been designed by him in the Corinthian style.

There seems to be little dispute over the fact that Callimachus was neither as a sculptor nor an architect to be placed in the van of the distinguished artists of early Greece. As a sculptor, in which capacity he is best known by his works, his style was stilted and artificial, rendered so by the artist’s disposition to be finicky and fastidious in his execution. Indeed, he is said to have been

unwearied in polishing and perfecting, and to have sacrificed the grand and sublime in the exercise of too great refinement and purity. Callimachus was never satisfied with himself, and possibly on that account others were not satisfied with him, as a certain degree of self-esteem is necessary to invite public approval. The Greeks gave him a name, based upon his peculiarities, which Pliny has translated as "_Calumniator Sui_." His faculty for invention was evidenced in other respects also, as he is credited with having originated the art of boring marble, and Pausanius describes a golden lamp which he invented, and which he dedicated to Athene, which when filled with oil burned exactly a year without going out.

It may be said broadly of the Grecian people in their employment of the three grand orders of architecture that the first two—namely, the Doric and Ionic—more closely harmonized with the dignity and nobility of their national character. In fact, Greece arrived at the pinnacle of her civilization and brought her philosophy of human existence not only in theory, but in practice, to its highest ideals before the Corinthian order of architecture appeared to claim a share in her artistic reputation. The stately solidity of the Doric and the graceful purity of the Ionic lent the perfection of architectural framework to the mental strength and loftiness of ideal of the Hellenic people. They seemed to accord with the philosophy that was originally preached from under the shadow of their pediments and entablatures. We can almost see the doubting and mystified Theon stepping from the Doric portico where Zeno held forth, to compare that philosopher's stoical dogmas with the doctrines of Prudence preached in the Ionic-encompassed garden of Epicurus, by a philosopher ever destined to be misconstrued and wrongfully interpreted.

"All learning is useful," taught Epicurus; "all the sciences are curious; all the arts are beautiful; but more useful, more curious and more beautiful is the perfect knowledge and perfect government of ourselves. Though a man should read the heavens, unravel their laws and their revolutions; though he should dive into the mysteries of matter, and expound the phenomena of the earth and air; though he should be conversant with all the writings and sayings and actions of the dead; though he should hold the pencil of Parrhasius, the chisel of Polycletus or the lyre of Pindar; though he should be one or all of these things, yet not know the secret springs of his own mind, the foundation of his opinions, the motives of his actions; if he hold not the rein over his passions; if he have not cleared the mist of all prejudice from his understanding; if he have not rubbed off all intolerance from his judgments; if he know not to weigh his own actions and the actions of others in the balance of justice, that man hath not knowledge, nor, though he be a man of science, a man of learning or an artist, he is not a sage. He must sit down patient at the feet of Philosophy. With all his learning he hath yet to learn, and perhaps a harder task, he hath to _un_learn."

The Corinthian order, on the other hand, notwithstanding all its charm, beauty and variety, seemed to lack that steadfastness of character which bound so firmly the other two orders to the hearts of the Grecian people, and was never admitted into their fullest trust and confidence. Indeed, it is generally conceded that the Corinthian model grew in favor as the architectural art of Greece declined; and only when Greece, losing her autonomy, began to lose her ambition and intellectual greatness and independence. It reached its fullest vogue with the later or Greco-Roman architects, who sacrificed much of purity in art for lavish and sightly display. With the Greeks the Corinthian was sparingly employed, and generally called upon for their smaller and less important buildings; on the other hand, with the Romans, enriched by additional features and ornamentation of their own, it became the favorite order, not alone for portico and temple, but for public and private buildings of every nature.

[Illustration: Three columns]

CHAPTER IV.

EARLY GRECIAN ARCHITECTS.

In the year 548 B.C. the great temple to Apollo at Delphi, the work of the legendary architects Agamedes and Trophonius, was destroyed by fire. Of the four temples to the same deity that had been reared upon the same site, this was the first in which marble was employed as a building material. Naturally the question will present itself, how could a temple built of marble be destroyed by fire? The answer is, that while the main walls of the cell and the columns, entablatures, pediments and other exposed parts of the early Greek temples were built of marble, stone or sun-dried bricks, the roofs were generally of wood, and were heavily timbered, sometimes calling for great strength to support marble tiles. Much of the interior building material was also of wood, as well as the statuary with which the earlier temples were lavished and enriched. Thus if fire was started within the building, either by accident or, as not infrequently happened, by the hand of an incendiary, there was sufficient combustible material for it to feed upon and to heat the entire structure, reducing the otherwise enduring marble to crumbling lime.

The temple of Apollo having been thus destroyed, the much revered and highly respected Oracle was left without shelter and a place of business. This state of things of course could not long be allowed to continue, and the Amphictyons, a legislative body, having under its special care the Delphic temple, at once came to the front and ordered a new temple built at a cost of about $300,000. One-fourth of this sum was to be paid by the Delphians and the remaining three-fourths were to be contributed by the other cities of Greece and those nations which were in the habit of consulting the Oracle—a very proper distribution of the expense, considering how extensive and widespread was the renown and appreciation of the priestess. Amasis, King of Egypt, volunteered a thousand talents of alumina, thus showing what his feelings were in the matter, and the Alcmæonidæ, one of the oldest and most aristocratic families of Athens, undertook the contract, it is hinted, mainly for political reasons. This may be true, as they were much involved in local politics, especially with the banishment of Pisistratus, the tyrant, and they may have seen an opportunity in the rebuilding of this temple to make themselves very popular. They certainly went about it in the right way to achieve such a result, and did actually gain much influence by their generosity and the broadminded manner in which they disregarded the strict terms of the contract to do handsomer and better work than it called for. One particular illustration of their liberality has attracted the attention of the historian: it was the building of the temple in Parian marble, instead of Porine stone. While the Alcmæonidæ were prosecuting the work in this generous spirit, they did not neglect their fallen enemies, the Pisistratidæ, and threw out occasional innuendoes to the effect that the Pisistratidæ could tell more about the origin of the fire that destroyed the late temple than they evidently cared to, thereby intimating a crime as against their rivals that it might have been difficult to have proved. They even won the Oracle to their side by similar simple and ingenuous methods, with the result that ever afterward the Oracle did not hesitate to speak a kind word for the Alcmæonidæ and favor their native city, Athens.

The architect of this new temple was Spintharus, a Corinthian. As nothing further seems to be known of him, we have been somewhat particular to mention the importance of this work, to show that Spintharus was an artist who stood very high in his profession at the time. But as the temple was one of the longest in process of construction, taking about seventy-two years to complete, it is not likely that Spintharus lived to enjoy the full fruition of his work.

It may be of interest to add that no structure of its kind throughout all Greece was made the depository of richer or more extensive treasure than this temple to Apollo at Delphi, a fact not to be marvelled at if we do not lose sight of the Oracle. We have already seen how it excited the cupidity of the brothers Agamedes and Trophonius. What they appropriated to themselves from the rich vaults of its predecessor was, however, comparatively insignificant to the wholesale robberies that went on from time to time of the fifth temple designed by Spintharus. Herodotus says that the wealth of Delphi was better known to the Persian Xerxes than were the contents of his own palace, and that after forcing the pass of Thermopylæ he detached a portion of his army to capture Delphi. It failed to do so, only through the interposition of the Oracle or some other deity. Many years afterward the Phocians plundered the temple of what might be represented by $10,600,000 of our money. Still later the Gauls also made a rich haul, which the Romans afterward found in their city of Tolosa unexpended, probably because there was so much of it; and Nero is said to have taken from it five hundred bronze statues at one time.

But these robberies fade into insignificance when the insult heaped upon the Delphians and their Oracle by Constantine the Great is recalled. This Roman vandal not only removed the sacred Tripod and Brazen Column which supported it, but degenerated their use to the adornment of the hippodrome of the new city he built on the Bosphorus. The Brazen Column may still be seen in Constantinople, but the sacred Tripod has disappeared forever. There is a little story connected with a first disappearance of the Tripod that may be worth the telling. It was lost at sea, but afterward recovered by some fishermen. When Pythia was asked to decide to whom it should be given, her answer was that it should be bestowed upon the wisest man in Greece. Accordingly it was sent to Thales of Miletos. He, however, was too modest to retain it, and passed it over to Bias as a wiser man; Bias was also embarrassed by the selection, and presented it to another of the Grecian sages; he to still another, and so on, until it had made the circuit of pretty much every person in Greece with any claim at all to superior wisdom. Finally, however, it came back once more to Thales, who successfully ended its itinerary by dedicating it to the Delphic Apollo.

One of the earliest of the great temples to be erected in the Ionic order was that begun in the Ionian city of Ephesus in Asiatic Greece by Ctesiphon, a Cretan architect born in Cnossus, and his son, Metagenes. This temple was erected to the glory of the many-breasted and mummy-like appearing Artemis, a goddess peculiar to the Ephesians, whom the Greek colonists there doubtless inherited from the Asiatic races that preceded them in their Ionian settlement. There was nothing of the graceful, virgin-like characteristics of Apollo's sister, the Arcadian Artemis, in this Ephesian goddess, but the Ionian Greeks were quite partial to her, attended her with eunuch priests, and built in her honor this temple, so grand and magnificent that it was regarded as one of the seven wonders of the world.

Before alluding to some of the interesting facts that have been preserved concerning the early history of this great temple it may not be out of place to touch upon a custom which prevailed in Ephesus in respect to the employment of architects, which Vitruvius relates. He says: “In the magnificent and spacious Grecian city of Ephesus an ancient law was made by the ancestors of the inhabitants, hard in its nature, but nevertheless equitable. When an architect was entrusted with the execution of a public work, an estimate thereof being lodged in the hands of a magistrate, his property was held as security until the work was finished. If, when finished, the expense did not exceed the estimate, he was complimented with decrees and honors. So when the excess did not amount to more than a fourth part of the original estimate, it was defrayed by the public, and no punishment was inflicted. But when more than one-fourth the estimate was exceeded, he was required to pay the excess out of his own pocket.”

The honest Vitruvius almost sighs as he adds: “Would to God that such a law existed among the Roman people, not only in respect to their public, but also of their private buildings, for then the unskilful could not commit their depredations with impunity, and those who were most skilful in the intricacies of the art would follow the profession! Proprietors would not be led into an extravagant expenditure, so as to cause ruin; architects themselves, from the dread of punishment, would be more careful in their calculations, and the proprietor would complete his building for that sum or a little more, which he could afford to expend. Those who can conveniently expend a given sum on any work with the pleasing expectation of seeing it completed would cheerfully add one-fourth more; but when they find themselves burdened with the addition of half or even more than half of the expense originally contemplated, losing their spirits and sacrificing what has already been laid out, they incline to desist from its completion.”

There are, perhaps, some people even at the present time who can be found to echo these sentiments of Vitruvius, and exclaim: Would to God that such a law existed among the American people, especially in New York and Chicago!

Theodorus of Samos, it will be remembered, laid the foundation of the temple to Artemis of Ephesus in the year 600 B.C. To guard against the destruction of the temple by earthquakes, a marshy site was chosen, and Theodorus insured a firm foundation, by using charcoal, which was rammed down solidly, and then covered with fleeces of wool. Ctesiphon and his son did not, however, begin the superstructure until about forty years later.

The dimensions of the building were very extensive, and although the architecture was full of grandeur, grace and beauty were not sacrificed. The length was four hundred and twenty-five feet; the width two hundred and twenty feet. One hundred and twenty-seven Parian marble columns, each sixty feet in height, surrounded the cell in double rows, sixteen appearing in the front and rear façades, and forty each on the sides. Herodotus states that most of these columns were presented by the rich Crœsus, and some by other kings. The cell, according to some authorities, was devoid of a roof, but Mr. Wood, in his “Discoveries at Ephesus,” indicates otherwise. The whole edifice, both exteriorly and interiorly, presented great richness and elaboration of carving. The shafts of the columns in front of the building were carved in relief, in three broad bands, to nearly half their height, and those in the rear, in one band, to about one-quarter of their height. The frieze and pediments were also worked out by the chisel of the sculptor in designs of great and imposing beauty.

Many of the stones used in the building were very massive. An idea of how huge some of these blocks were may be gathered from the fact that the architrave alone contained pieces of marble thirty feet long, and that Ctesiphon and Metagenes were forced to invent special machinery and contrivances to convey the stones for the columns to the building from the quarry eight miles distant. Vitruvius explains these contrivances as follows: “He [Ctesiphon] made a frame of four pieces of timber, two of which were equal in length to the shafts of the columns, and were held together by the two transverse pieces. In each end of the shaft he inserted iron pivots, whose ends were dovetailed thereinto, and run with lead. The pivots worked in gudgeons fastened to the timber frame, whereto were attached oaken shafts. The pivots having a free revolution in the gudgeons, when the oxen were attached and drew the frame, the shafts rolled round, and might have been conveyed to any distance. The shafts having been thus transported, the entablatures were to be removed, when Metagenes, the son of Ctesiphon, applied the principle upon which the shafts had been conveyed to the removal of those also. He constructed wheels about twelve feet in diameter, and fixed the ends of the blocks of stone whereof the entablature was composed into them; pivots and gudgeons were then prepared to receive them in the manner just described, so that when the oxen drew the machine the pivots, turning in the gudgeons, caused the wheels to revolve, and thus the blocks, being enclosed like axles in the wheels, were brought to the work without delay. An example of this species of machine may be seen in the rolling stone used for smoothing the walks in palæstræ. But the method would not have been practicable for any considerable distance. From the quarries to the temple is a length of not more than eight thousand feet, and the interval is a plain without any declivity. Within our own time, when the base of the colossal statue of Apollo in the temple of that god was decayed through age, to prevent the fall and destruction of it, a contract for a base from the same quarry was made with Pæonius. It was twelve feet long, eight feet wide, and six feet high. Pæonius, driven to an expedient, did not use the same as Metagenes did, but

constructed a machine for the purpose by a different application of the same principle. He made two wheels about fifteen feet in diameter, and fitted the ends of the stone into these wheels. To connect the two wheels he framed into them, round their circumference, small pieces of two inches square, not more than one foot apart, each extending from one wheel to the other, and thus enclosing the stone. Round these bars a rope was coiled, to which the traces of the oxen were made fast, and as it was drawn out the stone rolled by means of the wheels; but the machine, by its constant swerving from a direct, straightforward path, stood in need of constant rectification, so that Pæonius was at last without money for the completion of his contract." The uninitiated who have speculated as to how the ancients succeeded in moving and transporting considerable distances such huge blocks of stone, without the assistance of our modern machinery and contrivances, are given in this quotation from Vitruvius some hint as to the ingenuity and inventive ability of the early architects and builders.

The temple, however, was slow in building, and Ctesiphon and Metagenes, after writing a book on their great architectural work, passed away in due course of time. Their places were filled by other architects, of whom there is no record, but Demetrius, a priest of Diana, together with Daphnis and Peonius, Ephesian architects, finally completed the work some two hundred and twenty years after it was begun by Ctesiphon and his son. In the course of that long interval, Scopas, an architectural sculptor of Paros, of whom there will be more to relate as we go on, contributed one column, which was regarded as so beautiful that it was accepted as a model for those that followed.

Together with its architectural glories, the interior was made a depository for many of the finest works of the great artists of antiquity, and Scopas is said to have introduced Caryatides here. This is doubted, but he certainly furnished a very grand statue of Hecate; and Praxiteles, with his almost equally gifted son, adorned the shrine.

Tradition relates that upon the very night that the great Alexander was born, the Ephesian temple was destroyed by fire, through the rapacious greed for notoriety of one Herostratus. This antique fire-bug, when put to the torture for his crime, confessed that his only object was to gain immortality for his name, an ambition which he succeeded in accomplishing through the stupidity of the states-general of Asiatic Greece. They decreed that the name of Herostratus should never be mentioned, and of course it always was, as all the contemporary historians felt impelled to record the fact that a man by the name of Herostratus was not to be mentioned, and to give the reasons therefor, and much more about Herostratus which, had there been no decree, might have been left unsaid. The result was and has been that a crank of antiquity has lived by name for twenty-five hundred years, and is quite likely to live for as many more.

When Alexander the Great reached maturity, doubtless feeling the depression consequent upon having his advent into the world which he was destined to dominate, associated with the destruction of so magnificent a temple to the Asiatic Diana, offered, it is said, to pay the cost of its restoration, provided—there is frequently a proviso coupled with these liberal offers—provided his name should be inscribed on the new edifice. While the Ephesians were made glad by the offer, they did not readily fall in with the proviso. The cleverness of their diplomatic reply, however, appealed to the susceptible side of Alexander's human nature, and effected a compromise. They told the Macedonian that "it was not right for a god to make offerings to gods."

The architect for the new temple was the great favorite of Alexander and his fellow-countryman, Dinocrates, who it is said rebuilt the edifice on even a more extravagant scale than was the first. Much of the marble and sculpturing of the old temple entered into the new, and the painters, statuaries and sculptors of the time again lavished upon it their best art. The walls were embellished from time to time by Parrhasius and Apelles; and Timarete, the first female artist of note of whom there is any record, contributed a picture of the honored Artemis. It is related that the folding doors or gates of this new temple were made of cypress that had been allowed to season for four generations, and that when the pieces of cypress wood were glued together the glue was allowed to remain for four years to harden. Mutianus, a Roman architect, states that when he found them, which was four hundred years afterward, they were as fresh and beautiful as when new.

Some remains of the splendor of this pagan temple are still doing architectural duty. The great dome of the beautiful Byzantine church of Santa Sophia in Constantinople, now a Turkish mosque, is supported by columns of green jasper, brought from the Ephesian temple by the Roman Emperor Justinian, and two of the pillars in the cathedral at Pisa are also from the same source.

There is some confusion as to the works of art and decorations associated respectively with the two temples just described which it would be vain to attempt to clear up, believing that it matters but little, inasmuch as it is not likely that Herostratus could have destroyed completely the first temple, and that the services of Dinocrates were engaged more in the line of making good the damage done than in erecting an entirely new edifice. The upper colonnades of Corinthian columns, however, which Mr. Wood

shows as appearing in the interior of the temple, are clearly the work of Dinocrates.

Demetrius, the priest of Diana, and his associates, Peonius and Daphnis, the three architects who completed the first Artemesian temple, having flourished over two hundred years after the foundation of that structure was laid, are not, of course, to be classed among the earlier of the Grecian architects, and, properly, should not be treated under this heading; but as they are all grouped together in the erection of another great Asiatic-Greek temple, and are not further met with, it may be just as well to add what there is in respect to them at this time.

The temple referred to was that dedicated to Apollo in the Ionian city of Miletus, not far distant from the scene of the joint labors of these architects at Ephesus. Its order was also Ionic, and although not as large as that to Artemis, it could have been very little, if any, inferior to it in columnar effect and general impressive beauty, if not grandeur. It was three hundred and two feet in length by one hundred and sixty-four feet in width, and, like the temple at Ephesus, was surrounded by double rows of columns, each column, however, being sixty-three feet in height. Indeed, Strabo, the celebrated Roman traveller and geographer, who visited the ruins of the temple during the first century before the Christian era, testifies that “it is the greatest of all temples,” and adds that it remained without a roof “in consequence of its bigness”; but this allusion to its roofless condition is probably due to the fact that the building was never wholly completed. Pausanias also gives it high praise, and speaks of it as one of the wonders of Ionia, and Vitruvius numbers it “as one of the four temples which had raised their architects to the summit of renown”[2]—a renown, it would seem, that has been very much begrudged them, as the literature of their time furnishes practically no data in regard to them personally, and what estimate can be formed of them is wholly based upon the importance of their works.

Peonius, we are told, was an Ephesian, but as to even the nativity of the other two architects we are in the dark, although Daphnis is supposed to have been a Miletian. There is also some little uncertainty as to the exact date when they exercised their profession, but it is probably safe to say that it was sometime within the first half of the fourth century before Christ.

Two columns of the great temple to Apollo have stood proudly against the attacks of time, and although scarred by their long battles, are yet evidencing the glories of a structure of which they were once but an insignificant part.

In the year 555 B.C. there lived four architects, to whose skill was entrusted the building of a temple that should be in all respects worthy to stand for the respect due the dignity, power and extreme longevity of the great Olympian Zeus—the king-god of the Greeks.

The foundation for this shrine was laid in the time of Pisistratus, a tyrant of Athens, who contributed several architectural works to that city, but whose several banishments greatly interrupted their building. This was particularly the case with the great temple to Zeus. However, it was sufficiently advanced for Pisistratus to dedicate it before he fell from power. It has been stated that it was due to the genuine dislike which the Athenians felt for Pisistratus and his sons, who succeeded him, that four hundred years were allowed to flow by before the temple was finished. This is hardly just to a ruler of great loyalty to his native city, and of unquestioned integrity in the discharge of his public duties. It is more probable that the delay was due to the animosity of the rival Athenian family of Alcmæonidæ, who, piqued by jealousy, fanned a flame of opposition to the works of Pisistratus that continued for several centuries.

Antistates, Antimachides, Calleschros and Porinus were the four architects engaged by Pisistratus, who, like their professional brothers employed on the temples of Diana, Apollo and Ceres, were, according to Vitruvius, entitled to immortality for the grandeur of their works, but about whom there is no other information to be given.

This temple to Jupiter was not built upon the Acropolis at Athens, like that to the patron goddess of the city, Minerva, but upon a raised peribolos within the city below, and on the site of an earlier temple to the same god, erected in the time of Deucalion, but which had perished from the ravages of ages.

It was like most of the early Doric temples, of peripteral construction, or surrounded by columns on all four sides. Aristotle, who saw it before it was finished, was so much impressed by its size that he compared it to the Pyramids; and one of his scholars remarked that “though unfinished, it called forth astonishment, and when finished would be unexcelled.”

Perseus, king of Macedonia, and Antiochus Epiphanes of Syria (176-164 B.C.) finally finished the cell and placed the Corinthian columns of the portico, employing for the purpose a Roman architect of great skill by the name of Cossutius. It was then, probably, that Livy made the remark “that among so many temples this is the only one worthy of a god.”

Sylla, however, when he laid siege to Athens, some forty years later, robbed the temple most unmercifully, carrying away with him many of the columns to Rome. But his work of destruction was more than compensated for by his successor, Hadrian, two hundred years still later, under the immediate direction of the celebrated Roman architect, Luigi Cannia. Hadrian, in his love of great architectural effects, was inspired to beautify the peribolos with a peristyle one hundred rods in length, and his architect contributed a new section to the temple itself, and added three grand vestibules.

The sacred enclosure, after Hadrian had finished it, which had a circumference of about twenty-three hundred feet, was ornamented by statues, contributed in great numbers by different cities. The length of the temple at this time, according to Stuart, was, upon the upper step, three hundred and fifty-four feet, and its breadth one hundred and seventy-one feet. The columns, which surrounded the cell, now all Corinthian, numbered one hundred and twenty-four, all of Pentelican marble, of which there are sixteen still standing. In the pronaos, or inner portico, Hadrian caused to be placed four statues of himself, two in Thracian and two in Egyptian marble, which were, perhaps, three more than a moderately modest man might have felt necessary.

Another gorgeous temple to the great Jupiter was begun about five years later than that at Athens by the architect Libon, an Eleian, in Olympia, which Lysias speaks of as “the fairest spot in Greece.” In Olympia the spiritual and physical natures of the Grecian people may be said to have combined in the perfection of development. Here the glories of the body, the capabilities of the finest muscular strength and athletic action, were exhibited in gymnasium and stadion, and here the religious spirit of the people arose to the fullest intensity, and as though doubly inspired by the action and strength of the perfect body, found expression in temple and sanctuary.

So great was the reward, so enthusiastic the reception accorded the champions in the athletic games of Olympia, that they call forth a protest from the sensitive Vitruvius, who seems to feel that the honors conferred upon them should have been reserved for the literary lights of the time. “The ancestors of the Greeks,” he complains, “held the celebrated wrestlers who were victors in the Olympic, Pythian, Isthmian and Nemean games in such esteem that, decorated with the palm and crown, they were not only publicly thanked, but were also, in their triumphant return to their respective homes, borne to their cities and countries in four-horse chariots, and were allowed pensions for life from the public revenue. When I consider these circumstances, I cannot help thinking it strange that similar honors, or even greater, are not decreed to those authors who are of lasting service to mankind. Such certainly ought to be the case; for the wrestler, by training, merely hardens his own body for the conflict; a writer, however, not only cultivates his own mind, but affords every one else the same opportunity, by laying down precepts for acquiring knowledge and exciting the talents of his reader.”

So attractive was this spot on the banks of the Alpheus in Ellis, in natural charm, as well as in the purposes for which it was visited, that it is here, as nowhere else in Greece, with the possible exception of the Acropolis at Athens, the Grecian architects lavished their best skill and best illustrated their appreciation of the fact, that the effect of fine buildings is greatly augmented by grouping them gracefully together in one place, producing, as it were, an architectural picture. “Many objects,” says Pausanias, “may a man see in Greece, and many things may he hear that are worthy of admiration, but above them all the doings at Eleusis and the sights at Olympia have somewhat in them of a soul divine.”

The worship of Zeus was an old worship in Olympia, so that when Libon was entrusted with authority to erect a new temple to that deity, out of the spoils taken in subjugating the Pisans and other neighboring cities which had revolted from the Eleans, he gave free reign to his art, and produced a Doric temple which rivalled that in Athens, though not as large.

Pausanias informs us that the Olympian temple was two hundred and thirty feet long, ninety-five feet wide and sixty-eight feet high; that it was surrounded by marble columns and covered with marble cut in the form of tiles. The front and rear pediments were adorned with sculpture, as well as the metopes of the frieze. The interior was of two orders of columns supporting lofty galleries, through which there was a passage to the throne of Jove “glittering with gold and gems.”

It was this temple of Libon’s that became, soon after its completion, the casket which held the _chef d’œuvre_ of Phidias, the colossal statue of Jupiter carved in ivory and gold, of which Quintilian observes that it added a new religious feeling to Greece. The story is well known how Phidias, being asked by his nephew Panænus, a painter, who assisted him in the decoration of the temple, how he could have conceived that air of divinity which he had expressed in the face of this noble statue, replied that he had copied it from Homer’s description of the god. Jupiter was presented naked to his waist, but draped from his girdle down. The significance of this was that the great Jove, knowing himself to be of heavenly origin, thought it best to conceal himself in part only from man. He was also given a beard for the reason that the Greeks, clinging to the Oriental notion, believed that beards carried with them an air

of majesty; an idea, by the way, which was not shared in by the Romans, who spoke with derision of their bearded forefathers, and permitted the wearing of beards only to those who were in disgrace, and to poor philosophers, who probably, like our poor modern poets, found a visit to the barber's an unnecessary and expensive luxury.

Rome during these early times, and before she had awakened to the cultivation of the arts at home, was prone to borrow from Greece the talent of which she was in need. It was about this time that we find the first record of such a call made by Rome upon her eastern neighbor for architects. The demand was answered by the two architectural sculptors Damophilus and Gorgasus, who were imported by the Dictator Posthumius to erect two temples in Rome, one to Castor and Pollux or, as some authorities assert, to Liber and Libera (Bacchus and Proserpine), which stood near the Forum and Temple of Vesta, and the other to Ceres, on the slope of the Aventine hill, near the Circus. These temples were vowed by Posthumius, in his battle with the Latins, 496 B.C., and were dedicated by Viscellinus some years later.

Before closing this chapter, in which the attempt is made to gather together some of the earlier architects of Greece, it may be as well to include within it a number of such artists who though not rising to the highest fame, or who were not connected with the most elegant buildings of their time, nevertheless had the good fortune to have their names preserved in history.

Pliny tells a rather amusing and interesting account of such an architect by the name of Bupalus, who probably flourished about the year 524 B.C. He is said to have come from a very old family of artists who exercised the art of the statuary from the beginning of the Olympiads; but as Pliny simply speaks of him as an architect and artist, but does not mention any building attributed to his skill, he becomes a subject for notice only in connection with the Iambic poet Hipponax, whom he used his art to torment. Pliny relates that Bupalus and his brother Athenis amused themselves by making caricatures of the satirical poet. Hipponax was undersized, thin and ugly, and probably, like the modern poet Pope, suffered his physical defects to give him a cynical view of life. The caricatures of the playful Bupalus and Athenis naturally affected unpleasantly his _amour propre_, and he employed the weapon at his command, his ironical pen, to strike back at his tormentors, with the result that he gave them a good pen lashing in a satirical poem, in which he also chastised his Ionian brethren for what he considered their effeminate luxury. In the same poem, also, he did not spare his own parents, and it is said that he even had the temerity to ridicule the gods.

There is, of course, always some one to start the story that a woman is at the source of all the infirmities that any particularly conspicuous man suffers from, and there are those who claim that Bupalus did not originate the trouble, but that it started through the fact that the architect had a very beautiful daughter of whom Hipponax was greatly enamored. Like the earlier Iambic poet Archilochus, who got into a similar scrape, the girl's father refused to permit his daughter to marry a poor little withered poet, with the result that the poet's life was ever after embittered. How very bitter Hipponax became, especially against the ladies, is illustrated by a remark which is attributed to him: "There are," he said, "only two happy days in the life of a married man—that in which he receives his wife, and that in which he carries out her corpse."

After his death Leonidas of Tarentum, in an elegant epigram, warned travellers not to pass too near his tomb, lest they rouse the sleeping wasp. The grave of Hipponax, by the way, instead of being covered with ivy and roses, like that of a mild poet, was planted with thorns and thistles.

Pausanias mentions several of these more obscure architects. Agnaptus was one, who built a porch in the Altis, or wall at Olympia, called afterward by the Eleans the "porch of Agnaptus," and Antiphilus, Pothæus and Megacles were three other waifs on our sea of oblivion. They were responsible for the Treasury of the Carthaginians also at Olympia. Pyrrhus, with his two sons, Lacrates and Hermon, built the Olympian Treasury of the Epidamnians. There were ten of these Treasuries, by the way, raised by different states, which were not only architecturally very beautiful, but which contained statues and other offerings of great value.

Strabo mentions an architect and sculptor by the name of Hermocreon, who designed a gigantic and beautiful altar at Parium on the Propontis in Asia Minor; and Eurycles, a Spartan architect, who built the baths at Corinth, and "adorned them with beautiful marbles," must not be overlooked, although he may have been of a much later date.

FOOTNOTES:

[2] The other three temples which Vitruvius praised thus highly were those to Diana at Ephesus, Jupiter Olympus at Athens, and Ceres at Eleusis.

CHAPTER V.

THE ARCHITECTURAL EPOCH OF PERICLES.

The age of Pericles was so distinctively an era in the advancement of the arts, especially architecture, not alone in the city where Athene shed her divine intelligence and tutelary influence with generous favor, but throughout all the Hellenic states, and has left so many models and criterions for the architects of all time to follow, that a few words in reference to Pericles himself and the sculptor Phidias, into whose hands he entrusted the direction of his public buildings and the adornment of Athens, may be admissible, before we consider the architectural geniuses who sprung forward to meet the great requirements of the time.

Pericles was a descendant of that noble and refined, if sometimes unfortunate, house of Alcmæonidæ, which did so much for the Delphic temple of Apollo, and a son of Xanthippus, the victor of Mycale, and Agariste, niece of Cleisthenes, founder of the later Athenian constitution. The date of his birth is not known, but that he early evinced a leaning toward the fine arts and philosophy is recorded. Under Pythocleides he studied music, under Damon political science, under Zeno philosophy; but it remained for the erudite Anaxagoras to give the final burnish to his character and thought. He was therefore, both by birth and disposition, as well as cultivation, possessed of a mind singularly comprehensive in its grasp of the advantages which the arts of peace could contribute to the progress of his people, and naturally turned his attention to their exploitation and development, when he became dominant in the year 444 B.C. His rule of peace lasted but thirteen years, or until the breaking out of the Peloponnesian war, but was crowded with numerous artistic and architectural triumphs.

That he may have gone a step too far in the encouragement of pleasure and the peaceful virtues among a people of warlike antecedents and a future before them of foreordained defence and conquest, if not final defeat, may be a subject for speculation; but that he gave an impetus to literature and art, and by the fervent warmth of his patronage fostered the growth of genius in a way that had not been equalled before his time, and which has never been excelled since, is the principal reason, doubtless, for his immortality.

His head was abnormally long, a defect which the artists of his time invariably corrected with a helmet when painting or sculpturing his portrait, and the contemporaneous comic poets and satirists as continually ridiculed in verse and jest. Speaking of his eloquence and powers of persuasion, Thucydides relates a pleasant story in respect to his dexterity in this regard. When Archidamus, king of the Lacedæmonians, asked Thucydides whether he or Pericles was the better wrestler, he replied: “When I have thrown him and given him a fair fall, he, by persisting that he had no fall, gets the better of me, and makes the bystanders, in spite of their own eyes, believe him.” But in other respects his physique was well proportioned and his bearing noble and commanding. His manner was dignified and reserved, his eloquence strong, fearless and convincing, and his general appearance such as to inspire the people to compliment him with the name “Olympian Zeus,” a character in which his portrait was also painted by his favorite, Phidias.

An English writer well says that the age of Pericles was “the milky way of great men,” for it was certainly clouded to whiteness with intellectual stars. The names associated with this era are not only among the most celebrated in all Grecian history, but among the most renowned that have sprung forward in the history of all the world. Poets, philosophers, dramatists, musicians, sculptors, painters, architects, not only arose in great numbers under his fostering encouragement, but to the highest eminence in their respective avocations. In fact, it seems as though the human plant that had long been growing, strengthening and broadening upon Hellenic soil had suddenly sprung into the fullest flower and enveloped itself in intellectual beauty.

The Athens which we so frequently see pictured in all her restored architectural grace and grandeur, the Athens which from her Acropolis of chiselled white so proudly surveys the Ægean sea and surrounding plains, is the Athens of Pericles, noblest of all cities in the pursuits of virtue, of beauty and contentment, and in the pure realization of that happiness which the practice of the arts alone can afford.

The budding of Athenian architectural magnificence may be said to have begun under Themistocles and Cimon, the immediate predecessors of Pericles, but not to have ripened and flowered in its perfection until his advent into power. Then it was that the task of building a city in every way worthy of the people who had proved their prowess before the Persian hosts in war, and who in peace could delight in the musical poems of Homer, was pushed to a speedy realization with enthusiasm.

Nothing in all the biography of Pericles has contributed so greatly to the perpetuity of his fame as this attention which he gave to the development of the architectural magnificence of Athens. “That which gave most pleasure and ornament to the city of Athens,” says Plutarch, “and the greatest admiration and even astonishment to all strangers, and that which now is Greece’s only evidence that the power she boasts of and her ancient wealth are no romance or idle story, was his construction of the public and sacred

buildings. The materials were stone, brass, ivory, gold, ebony and cypress-wood; the artisans that wrought and fashioned them were smiths and carpenters, moulders, founders and braziers, stone-cutters, dyers, goldsmiths, ivory-workers, painters, embroiderers, turners; those again that conveyed them to the town for use, merchants and mariners and ship-masters by sea; and by land, cartwrights, cattle breeders, wagoners, rope-makers, flax-workers, shoemakers and leather-dressers, road-makers, miners. And every trade in the same nature, as a captain in an army has his particular company of soldiers under him, had its own hired company of journeymen and laborers belonging to it banded together as in array, to be, as it were, the instrument and body for the performance of the service. Thus, to say all in a word, the occasions and services of these public works distributed plenty through every age and condition."

"Architecture," says Robert Adam, "in a particular manner depends upon the patronage of the great, as they alone are able to execute what the architect plans." This being so, the architects of his time had in Pericles a patron in every way worthy their best efforts. Indeed, so ambitious was he to grace the city of his nativity with all the beauties of architecture that his enemies found here a pretext for censure, and complained that he spent too much of the public treasure for such a purpose. He met the criticism, however, with the argument that those who pursued the arts of war should not be the only ones to receive support at the expense of the state, but that those who possessed the skill and industry of true artists and artisans were quite as much entitled to public encouragement and support as the soldier.

This answer for a time appeased the clamor of the opposition, which had been set up against what they would lead the people to believe was extravagance and wastefulness on the part of Pericles. But it soon broke out again. When finally it became no longer bearable, Pericles addressed his accusers and said: "If you think that I have expended too much let the money be charged to my account, not yours, _only let the new edifices be inscribed with my name and not that of the people of Athens_." It is to the credit of the Athenians that their pride was touched by the words of their ruler and their cupidity restrained. They at once replied that Pericles might spend as much of their money as he pleased, and they even went further, and insisted that he should not spare the public treasury in the least. Like all great men, Pericles was assailed in a variety of ways. When his enemies did not accomplish their purpose in bringing him to public disgrace by one method of assault, they tried another. We have seen how they failed in one instance; another was similar in accusing him, in complicity with Phidias, of appropriating to his own use the public treasure, donated to pay for the golden plates on the chryselephantine statues of the latter's creation. But this charge also not proving successful, they attacked his religious character, strange as it may appear, when it is remembered how deeply he was interested in erecting temples of pagan worship. But he survived the slanders of his time and continued his aims and purposes in life, content, doubtless, that posterity should judge him aright, as did the majority of the people of his own time. His last words are perhaps the best epitome of his life's work: "No Athenian ever put on black through me."

Teleclides has put into verse the great surrender which the Athenian people appeared finally to make to Pericles of their rights in peace and war:

"The tribute of the cities, and, with them, the cities too, To do with them as he pleases, and undo; To build up, if he likes, stone walls around a town; And, again, if so he likes, to pull them down; Their treaties and alliances, power, empire, peace and war, Their wealth and their success forevermore."

As already stated, in no branch of the arts did the age of Pericles make a deeper and more lasting impression than in that of architecture. Although the Doric order was employed many hundred years before his time, and the Ionic scarcely less many, yet the finest types of each and the examples of these orders which stand for their most perfect and artistic development are to be found in the Acropolis at Athens in the time of Pericles, the Parthenon serving as the criterion of one and the Erechtheum as the model of the other. That these orders should have been brought to such perfection and endowed with their crowning dignity and grace, must alone prove without further argument, if need be, that the architectural talent and artistic sense of the age was incomparable.

The part which the great sculptor Phidias played in the art drama of his time has been already alluded to, but not sufficiently, perhaps, to exclude a further reference to him.

The comparison has often been made between Phidias and the talented revivalist of the fifteenth century, Michael Angelo, and a casual consideration of the two eminent artists would indicate that it was a proper one. They were both sculptors, both painters, both engravers (Phidias of gems), but they were not both architects, as is erroneously assumed. As to the respective degrees of talent which each manifested toward the branches of art which he professed, they also differed widely. In sculpture the school of Michael Angelo will not outlive that of Phidias, but in painting, especially in its application to mural decoration, the Greek must bow

to the Italian. In architecture also Phidias possessed none of the technical knowledge and skill which in Michael Angelo enabled him to suspend the great dome of St. Peter's "as if in the air," and which was so important a factor in his long artistic career, manifested in other ways as well, and gaining for him perpetual applause. However, the two artists may be well compared, inasmuch that they both created epochs of their own; and both excelled in exhibiting a noble understanding as to the high and exalted possibilities of art that has never been equalled.

Phidias's comprehensive grasp of broad artistic effects had as much to do, probably, with gaining for him the favor of Pericles as his technical skill. Quintilian calls him the "Sculptor of the gods." He realized the greatness of large things and could calculate their power in influencing the imagination and understanding. He was once invited, together with his contemporary artist, Alcamenes, to design a statue of Minerva, destined to be placed upon a high column. When both statues were finished and exhibited, that made by Alcamenes was at once preferred on account of its elegance of finish, while that by Phidias was rejected as being rough and crude. Phidias, however, insisted that each should be shown from the high pinnacle upon which it might ultimately be placed. When this was done all the elegant graces of the statue of Alcamenes were lost to sight, as well also the apparent roughness of that by Phidias, which now took on the perfect proportions he had foreseen. This story will serve to illustrate the breadth of his artistic discernment.

Of all the artists of his time, Phidias was by far the best gifted to have placed in his hands, by Pericles, the supervision of the public buildings of Athens, and to have entrusted to his discretion and judgment the planning, posing and arranging of the grand architectural _mise en scène_, which his patron had determined should be set there. If Phidias did not draw the actual plans of a building or other structure, his judgment could indicate its order, its location and such other characteristics it should possess to harmonize with the features with which it was to be associated. He could group the majestic masonry of his time in grand display, could beautify it with his own chisel, and could form and mould the complete architectural picture. If he was not the architect of the Parthenon, he at least enhanced its effect with the magnificence of his sculpturings and designs in the metopes of the frieze and the tympanums of the pediments, some of which are still to be seen among the "Elgin marbles" in the British Museum, of which Canova remarked they would alone compensate for a visit to England. It is not improbable, also, that he may have suggested the Caryatides of the Erechtheum, and proved to the Egyptians, from whom the architectural idea was borrowed, how far more beautifully and gracefully such figures could be carved in Athens than on the banks of the Nile.

There can be no doubt as to the value of statuary, which was the special province of Phidias, in enhancing the _ensemble_ of Grecian architectural grouping, and particularly valuable was the colossal figure of Minerva Promachus in contributing to the grandiose effect of the Athenian Acropolis. This noble work of Phidias was seventy feet high and made entirely of bronze, said to have been taken from the Medes, who disembarked at Marathon. The colossal goddess stood exposed, and in a position where, in looking far away over the Ægean sea, she might be an inspiration to the returning Athenian mariner, and where, in glancing from her lofty eminence, "she seemed, by her attitude and her accoutrements, to promise protection to the city beneath her, and to bid defiance to her enemies."

Another architectural statue, if it may be called such, was that of the same goddess, in gold and ivory, which dominated the interior of the Parthenon. This work of Phidias, second only in beauty and size to the chryselephantine statue of Jupiter at Olympia, is said to have cost $465,000. The figure of Minerva was forty feet in height, and was presented standing in a tunic which reached to her feet. A casque covered her head, her right hand held a spear, and her left a figure of Victory. The exquisite workmanship of the carving on the buckler resting at the feet of the deity came near involving Pericles and Phidias in another web of trouble, for it was asserted that the sculptor had introduced his own portrait and that of his patron among the combatants of a battle between the Athenians and Amazons, there portrayed. The captious objection was set up that such a liberty was insulting to Athene. Phidias, as related by some writers, was cast into prison for this act of impiety, and died there. Others claim, however, that this was not so, but that Phidias, before sentence could be passed, fled to Elis, where he at once entered upon the work of modelling the great statue of the Olympian Jupiter.

In respect to both statues, he was implicated with Pericles, as accused by his enemies, with pilfering the gold donated for their construction. These various accusations have led to considerable confusion in respect to much of his personal history and final end, and although it was proved by removing the gold plates and weighing them, that he was not guilty of the alleged crime, it is very probable that his death was as much due to disappointed hopes and mortification consequent upon the false charge as it was to any public executioner of the time.

CHAPTER VI.

THE ARCHITECTS OF THE AGE OF PERICLES.

It is not the intention, in recalling some of the more conspicuous architects who flourished in the time of Pericles, to confine them to those only who were directly in his employ, but to group together all who became prominent factors in the architectural development of that age, both for some years before and after Pericles's reign of power.

To have carried forward the many important works which the great leader instituted, and which were advanced with a precision and rapidity remarkable for that or any other time, considering their size and importance, the skill and services of many architects were brought naturally into requisition. As a result we have the record of an unusually large number of such artists, and in respect to a few some little specific data relating to their lives. The architects, however, of many of the most important works are unknown.

If we approach Athens, like the Attic mariner of old, through the Piræus, one of its sea gates, we are attracted at once to the beautiful architectural display which this seaport town, some five or six miles distant from the Grecian metropolis, presents. The entrance to the harbor was ornamented with two lions, and the harbor-basin was fringed with magnificent colonnades and porticos, which disguised the warehouses and bazaars. Within the town were numerous temples, two theatres and other buildings of artistic effect and merit.

The road to Athens lay between massive fortified walls having a width of fifteen feet at the top, and built to a height of sixty feet. They were known as the "Long Walls," and they enclosed a space about the Piræus, said by Thucydides to have been not less than one hundred and twenty-four stadia in circumference, or about fifteen miles.

It is only just to state that the walls which led from Athens to Piræus, as well as those which connected it with the other sea gates of Munychia and Phalerus, were originally planned and partly executed under Themistocles and Cimon. Themistocles intended to construct these walls to a height of one hundred and twenty feet; but Pericles deemed this entirely unnecessary, and cut the height in two, as we have seen. He also added a third wall between that running to the north of the Piræan fortifications and that reaching to the Phalerum. Socrates speaks of having heard Pericles mention this wall to the people.

The architects for much of this massive mural work were Hippodamus and Callicrates, and because Pericles did not hurry them to the same extent that he hurried others engaged in perhaps less important, if more decorative, undertakings, Cratinus, the satirist, ridiculed the slowness of the work, while aiming a sly shaft of irony at Pericles's oratorical gifts:

"Stones upon stones the orator has pil'd With swelling words, but words will build no walls."

Hippodamus was one of the geniuses of his day, and has been called the "Wren of his age." Perhaps it would be more fitting to speak of Sir Christopher Wren as the Hippodamus of _his_ time, inasmuch as the architectural achievements of the Greek were on a much more magnificent scale than those of the Englishman. Among some of the conspicuous works credited to him was the grand Athenian Agora, or Forum, which was made up of a rich assemblage of colonnades, temples, altars and statues, all taking his name as the Hippodamæa. But whether he is to be credited with being more especially a civil engineer than an architect may be inferred from his work at the Piræus and in laying out entire cities.

He was called the "Excentric Architect" doubtless because he mingled with the practice of his profession a desire to be considered as thoroughly versed in all the physical sciences, a personal affectation which caused him to be ranked among the sophists. It is claimed that it was against Hippodamus that Aristophanes aimed much of his wit.

Hippodamus was the son of Euryphon of Miletus, one of the most famous of the Greek physicians and among the first to have knowledge of the difference between the veins and arteries, and the uses of each. As to his early education and advantages we are not informed, he being referred to by early writers only in a professional way.

Besides his employment upon the "Long Walls," the Agora and other edifices, Pericles engaged his talents, as we have intimated, in laying out the port of Piræus, which he did, with broad streets and avenues intersecting each other at right angles across the city. This plan of street construction he also introduced in other cities of Greece and her colonies with which he had to do, especially at Thurü on the site of the ancient Sybaris, which he visited with the Athenian colonists, and later at Rhodes. This last-mentioned city, which in the age of Pericles was one of the most beautiful, regular and prosperous of the times, was almost wholly the work of Hippodamus.

Callicrates, who assisted Hippodamus with the “Long Walls,” was also an associate of Ictinus, perhaps the greatest architect of his time, in the building of the Parthenon on the Athenian Acropolis. The architect Callicrates should not be mistaken for the Lacedæmonian sculptor of the same name who achieved great celebrity for his skill in carving the most minute objects, and of whom it is related that he made ants and other insects in ivory which were so very small that their limbs could not be distinguished by the naked eye. This seems all the more remarkable when it is remembered that the ancients had no magnifying glasses.

A walk of five or six miles under the shadows of the tall walls of Hippodamus and Callicrates to view the greater architectural glories of the city of Athens in the time of Pericles will doubtless repay us. While this queen city of the ancient world is enrobed in many triumphs of the builder’s art, we will probably pass them all by for the time being to examine more carefully the gems that stand forth from the Acropolis, glittering under the blue Grecian sky like white jewels in the proud city’s coronet.

This magnificent citadel, protected by Pelasgian walls and dedicated to the pagan deity Minerva, could be entered but upon one side, the western, where the massive gate or vestibule of the Propylæa occupied the centre. Fragments of this great gate still give evidence to the modern traveller of its former stately splendor.

“Here,” says Bishop Wordsworth, “above all places at Athens, the mind of the traveller enjoys an exquisite pleasure. It seems as if this portal had been spared in order that our imagination might send through it, as through a triumphal arch, all the glories of Athenian antiquity in visible parade. It was this particular point in the localities of Athens which was most admired by the Athenians themselves; nor is this surprising; let us conceive such a restitution of this fabric as its surviving fragments will suggest—let us imagine it restored to its pristine beauty—let it rise once more in the full dignity of its youthful nature—let all its architectural decorations be fresh and perfect—let their mouldings be again brilliant with their glowing tints of red and blue—let the coffers of its soffits be again spangled with stars, and the marble antæ be fringed over as they were once with delicate embroidery of ivy-leaf ... and then let the bronze valves of these five gates of the Propylæa be suddenly flung open and all the splendors of the interior of the Acropolis burst upon the view.”

If this imaginative restoration of the sublimities of the Propylæa is not sufficient to excite some interest in the building and the slave-born architect who was its creator, let the glowing words of Symonds be added, which refer not only to the grand vestibule itself, but to the Panathenaic processions which were wont to pass its gates.

“Musing thus upon the staircase of the Propylæa we may say with truth that all our modern art is but as child’s play to that of the Greeks. Very soul-subduing is the gloom of a cathedral like the Milanese Duomo when the incense rises in blue clouds athwart the bands of sunlight falling from the dome, and the crying of choirs upborne on the wings of organ music fills the whole vast space with a mystery of melody. Yet such ceremonial pomps as this are but as dreams and shapes of visions when compared with the clearly defined splendors of a Greek procession through marble peristyles in open air beneath the sun and sky. That spectacle combined the harmonies of perfect human forms in movement with the divine shapes of statues, the radiance of carefully selected vestments with hues inwrought upon pure marble. The rhythms and melodies of the Doric mood were sympathetic to the proportions of the Doric colonnades. The grove of pillars through which the pageant passed grew from the living rocks into shapes of beauty, fulfilling by the inbreathed spirit of man nature’s blind yearning after absolute completion. The sun itself, not thwarted by artificial gloom or tricked with alien colors of stained glass, was made to minister in all his strength to a pomp the pride of which was a display of form in manifold magnificence. The ritual of the Greeks was the ritual of a race at one with nature, glorying in its affiliation to the mighty mother of all life, and striving to add by human art the coping stone and final touch to her achievement.”

The Propylæa stretched in all about one hundred and seventy feet across the western side of the citadel, and was entirely built of Pentelic marble. In the centre was a portico sixty feet broad of six fluted Doric columns, each column thirty feet in height, and all supporting a noble pediment. From this portico projected on either side a wing, entered through three Ionic columns. Six Ionic columns assisted in supporting the roof of the vestibule. The marble beams of this roof were from seventeen to twenty-two feet in length and correspondingly solid. The ceiling was richly carved and ornamented. Immediately in the rear of the Ionic columns and at the end facing the Acropolis stood the terminal wall, with its five bronze gates, the centre one, which was the largest, being sufficiently broad to allow the passage of a chariot or other such vehicle. Beyond this wall and its gates was the posticum, adding eighteen feet to the depth of forty-three feet which the building otherwise possessed. The temple of the “Wingless Victory,” and the “Painted Chamber,” containing the finest works of the painter Polygnotus, as they have been named, formed the wings, which presented unbroken walls to the front, relieved only by the four Ionic columns that supported the graceful entablature and pediment of the temple of Niké Apteros on the right.

As the building was begun in the year 437 B.C., and was entirely completed within a period of five years, and was one of the most imposing structures of its day, Pausanias is led to reflect that, “in felicity of execution and in boldness and originality of design, it rivalled the Parthenon.” Lübke’s comment on the structure is: “Thus in this building the idea of fortress-like defence, as well as festive welcome, was equally expressed. Especially admirable, however, was the rich ceiling of the great three-naved court, both on account of the bold span of its beams and the magnificent decoration of the spaces between them (the coffers), which were brilliant with gold and colors.[3] The Ionic form of the columns in the interior also corresponded with this festive, cheerful character; while the two rows of columns on the outside, together with the rest of the exterior of the building, exhibited the seriousness and dignity of the Doric style.”

Thus has much been quoted in description and eulogy of this noble piece of architecture; would that as much might be quoted in respect to the talents and career of its gifted designer, but of him there is only the shadow of comment, from which it is possible to weave but the faintest fabric of certainty concerning his life.

His name was Mnesicles, and we are told that he was a slave born in the household of Pericles. That he should have been chosen to create so important an architectural work speaks for the privilege which the humblest born might hope to attain in rising to positions of trust and prominence in the days of that great leader. Mnesicles early manifested an aptitude for architecture, and was permitted by his illustrious patron and owner to exercise his talent in the erection of buildings of inferior consequence before being entrusted with more ambitious works. The Propylæa was not the only work of magnitude upon which he was engaged, nor was it the most beautiful, in the judgment of some critics, although the most important, for he was the architect as well of the graceful Doric temple of Theseus, which has always been regarded as one of the finest architectural conceptions the ancient city of Athens possessed.

[Illustration: THE FALL OF MNESICLES FROM THE PROPYLÆA.]

An incident in his life which awakened the affectionate interest of Pericles and the solicitude of the goddess Athene, whom he was serving so well, is told by Plutarch and other early biographers. It is in effect that while inspecting the almost completed work of the Propylæa he fell from the summit of the pediment and was most severely injured. He was taken at once to the house of Pericles, where he received the personal attention of the great ruler. It was while he lay at death’s door that it is said Minerva appeared to Pericles in a dream, and told him to administer to Mnesicles a medicine distilled from the wall-plant pellitory. This was done, and the life of the architect was spared. The only other fact associated with the life of Mnesicles which has been preserved to us is one mentioned by Pliny to the effect that the sculptor Stipax of Cyprus made a statue of the architect which became very celebrated in its time, and which was called _Splanchnoptes_. It was given this name because it represented a person roasting the entrails of the victim at a sacrifice, at the same time blowing the fire with his breath. There is nothing suggestive of the architect in question or his profession, but it is supposed to have been a statue of Mnesicles, from the fact that Pliny speaks of the subject as having been a slave of Pericles, who was cured of the wounds received in a fall from the Propylæa by an herb which Minerva had suggested should be given as a medicine. It is unfortunate that the statue has not survived to give us some idea of the features of at least one of the great architects of antiquity. Some recent discoveries on the Acropolis have, however, brought forth fragments which are supposed to have been parts of the base.

If there is any one of the Greek architects of the time of Pericles who can be said to have secured for himself a degree of popular notoriety throughout subsequent ages it is the accomplished Ictinus, the chief architect of the Parthenon and the designer of at least two other conspicuously beautiful buildings of which we know—namely, the temple of Apollo Epicurus, near Phigalia in Arcadia, and the temple of Ceres and Proserpine at Eleusis. It is, no doubt, due, however, to his connection with the Parthenon that his fame has so long endured.

As already stated, Callicrates assisted in the building of the Parthenon, and Phidias contributed the designs for the relief carvings in the pediments and metopes, executing much of the work with his own hands. Although Vitruvius says that “both Ictinus and Callicrates exerted all their powers to make this temple worthy of the goddess who presided over the arts,” it is not likely that Callicrates’s share in the work was equal to that of Ictinus, but was confined more to the heavy masonry, and in offering to Ictinus such advice as he might seek in giving to the building the greatest substantiality and permanency.

The Parthenon, which, among the several masterpieces of the Acropolis, must be acknowledged the greatest, stood upon a rocky elevation in the citadel, which so far elevated the structure as to bring the pavement of the peristyle upon a level with the capitals of the columns of the eastern portico of the Propylæa. This was the same site which had been occupied formerly by an earlier temple

to Minerva, known among the Athenians as the Hecatompedon on account of its proportions.

The Parthenon of Ictinus is said to have cost one thousand talents, or what would be equal to about $1,100,000 of our money. It was begun the year 422 B.C., and completed at the expiration of sixteen years. It conformed to the usual shape of the Greek temples, being rectangular and peripteral. The length from east to west was two hundred and twenty-seven feet and seven inches, the width a little over one hundred and one feet. The Doric order was employed for the exterior, the columns which surrounded the cell on all sides being thirty-four feet in height, with a diameter of six feet at the base. There were forty-six of these columns, springing directly from the stylobate or steps, all fluted with twenty channels, and each carrying its share of a very beautiful entablature. The gables or pediments at each end of the temple were of flat pitch. The total height of the building from the steps to the top of the gables was sixty-four feet. White marble from Mount Pentelicum, “wrought,” as Mr. Kinnaird expresses it, “with the exquisite finish of a cameo,” was the material employed for the entire structure, with the exception of the supporting timbers of the roof, which were wood covered with marble tiles.

The interior, to quote Mr. Kinnaird again, “enshrined the chryselephantine colossus with all its gorgeous adjuncts, and comprised sculptural decoration alone for one edifice exceeding in quantity that of all recent national monuments; consisting of a range of eleven hundred feet of sculpture and containing, on calculation, upward of six hundred figures, a portion of which were colossal, enriched by painting and probably golden ornaments. Here has been really verified the prediction of Pericles that, when the edifices of rival states would be mouldering in oblivion, the splendor of his city would be still paramount and triumphant.” In respect to the richness of its interior treasures, very much the same idea is expressed by Bishop Wordsworth, who says, in the course of his description of the building: “It would, therefore, be a very erroneous idea to regard this temple which we are describing merely as the best school of architecture in the world. It was also the noblest school of sculpture and the richest gallery of painting.”

The cleverness of the architects in insuring to the Parthenon, after its completion, the appearance of absolute harmony of proportion in all its outward lines, is one of their best claims to that celebrity which they have justly earned. As it goes so far toward illustrating their great professional skill, the reader may be interested in reading the language used by Professor Roger Smith of London in explaining the measures adopted by Ictinus and possibly Callicrates also, to correct the optical defects which the Parthenon might otherwise have possessed when completed.

“The delicacy and subtlety of these [optical illusions] are extreme, but there can be no manner of doubt that they existed. The best known correction is the diminution in diameter or taper, and the _entasis_ or convex curve of the tapered outline of the shaft of the column. Without the taper, which is perceptible enough in the order of this building, and much more marked in the order of earlier buildings, the columns would look top-heavy; but the _entasis_ is an additional optical correction to prevent their outline from appearing hollowed, which it would have done had there been no curve. The columns of the Parthenon have shafts that are over thirty-four feet high, and diminish from a diameter of 6.15 feet at the bottom to 4.81 feet at the top. The outline between these points is convex, but so slightly so that the curve departs at the point of greatest curvature not more than three-quarters of an inch from the straight line joining the top and bottom. This is, however, just sufficient to correct the tendency to look hollow in the middle.

“A second correction is intended to overcome the apparent tendency of a building to spread outward toward the top. This is met by inclining the columns slightly inward. So slight, however, is the inclination, that were the axes of two columns on opposite sides of the Parthenon continued upward till they met, the meeting point would be 1952 yards, or, in other words, more than one mile from the ground.

“Another optical correction is applied to the horizontal lines. In order to overcome a tendency which exists in all long lines to seem as though they drop in the middle, the lines of the architrave of the top step and of other horizontal features of the building are all slightly curved. The difference between the outline of the top step of the Parthenon and a straight line joining its two ends is at the greatest only just two inches.”

Still another correction which Professor Smith alludes to, in respect to the vertical proportions of the building, he does not discuss more than to say: “The small additions, amounting in the entire length of the order to less than five inches, were made to the heights of the various members of the order, with a view to secure that from one definite point of view the effect of foreshortening should be exactly compensated, and so the building should appear to the spectator to be perfectly proportioned.”

The Parthenon was not, as is popularly supposed, a temple for the worship of Minerva. The sanctuary for that particular purpose was in the Erechtheum, a triple temple, located upon the Acropolis not very far distant from the Parthenon, and having wings dedicated respectively to Minerva Polias, to Erechtheus or Neptune, wherein was a well of salt water, and to the Nymph

Pandrosus, daughter of Cecrops. The Parthenon, however, served as a national treasury and repository for the valuable offerings to the goddess, as well as “a central point for the Panathenaic festival,” where prizes might be distributed to the victorious competitors. Indeed, the decorations of Phidias would tend to corroborate this inference, as the sculptured low relief of the frieze represented the Panathenaic procession. The rich relief carvings in the tympanums of the front and rear pediments of the building, also by Phidias, the designs of which may be found described in almost any work on Grecian art, have been reproduced in some of the vignettes of this book.

In alluding to the Erechtheum, which, like the Parthenon and the Propylæa, still presents shapely and beautiful ruins to grace the Acropolis, attract the tourist and lend to the lover of art the best criterion of the ideal age of Grecian architecture, we must mourn the fact that the architect who designed this magnificent example of the Ionic order is not known, and it is not likely that he ever will be. The building was not finished at the time of the death of Pericles. Because of an inscription found in the Acropolis, and now in the British Museum, containing the particulars of a minute professional survey of the unfinished parts, made by an Athenian architect named Philocles, in the year 336 B.C., this architect has been given by some the credit of having been the author of the entire structure; but that he could not have been is clearly proven by the known fact that much of the temple was constructed, as we have stated, in the time of Pericles, or about one hundred years earlier. Nothing further, by the way, is known of Philocles than is here given.

About two thousand years had passed without that great leveller Time or the corroding influences of the elements marring to any very serious extent the beauty and completeness of the Parthenon, during which period it had suffered two changes most antagonistic to its original purpose, having been transformed at one time into a Christian church and at another into a Turkish mosque. In respect to the first transformation, it is well to note that the significance of its name was not wholly lost in the change. Parthenon means Virgin, and the Christians called the church into which they turned it the Church of the Blessed Virgin. It was seen entire by Spon and Wheeler in 1676. But when the Venetians, in their war with the Turks, eleven years later, besieged the citadel, they threw a bomb upon the roof of the noble structure, which, passing through it, ignited the powder which had been stored in the building by the Turks. The result was an explosion which divided and reduced the temple to its present condition, save for further depredations which seem hardly creditable. The iconoclastic Turks found this pride of Pericles most useful as a quarry upon which to draw for much of the material used in their own buildings, and it is to be regretted also that Lord Elgin should have found it necessary to enrich a distant museum in London with many of its most beautiful carvings, adding further desecration to “what Goth and Turk and Time had spared.” Vitruvius informs us that Ictinus, in collaboration with another architect, not otherwise mentioned, wrote a book upon the Parthenon, his greatest masterpiece.

After searching the world over for her dear, lost daughter, the beautiful Proserpine, who had been spirited away to the realm of Pluto, Ceres finally gave up the quest and mournfully settled down at Eleusis, a city in fertile Bœotia, about fourteen miles from Athens. Here was erected in her honor and in memory of Proserpine an Ionic temple by the people for whom she became sponsor. The Persians, during their invasion of Attica, burned the temple, but Pericles caused it to be rebuilt, and selected Ictinus as the architect. He erected a handsomer structure in the Doric style, which, it is said, was without exposed columns.

Whether Ictinus lived long enough to complete the temple to Ceres and Proserpine or not, or was called away for other purposes, is not known, but it appears that other architects were associated with its design and erection, both before as well as after his connection with it. Corœbus is mentioned also as an architect, in the employ of Pericles, who began the work on the mystic cell, but that his sudden death resulted in the substitution of Ictinus. It is more probable, however, that Ictinus had previously furnished the design of the building and that Corœbus had been merely acting under his supervision. Following Ictinus was another Athenian architect appointed by Pericles, and the designer of the demos of Cholargos. He is said to have built the pediment of the temple with the timpanum open, according to an ancient fashion, in order to light the cell, which, if Strabo is to be believed, was capable of accommodating thirty thousand persons.

In the time of Demetrius Phalereus, the immediate successor of Alexander, Philo, or Philon, as his name is sometimes written, a very eminent architect, also of Athens, was engaged to add a portico of twelve Doric columns to this temple of Ceres. That Metagenes of Xypete, and son of Ctesiphon, who has already been discussed in our allusion to the temple of Diana at Ephesus, should be mentioned as the architect who completed the entablature and an upper row of columns to this Eleusian temple, is probably a mistake. The time of Metagenes was, as we have seen, much earlier (about 560 B.C.), and while he might have been engaged upon the first temple to Ceres at Eleusis, it is quite impossible for him to have been employed by Pericles in the building of that with which Ictinus had to do.

When Alaric, the German, made his angry invasion into Greece in 396 B.C., because refused command of the armies of the Eastern empire, he destroyed very many works of Greek art, and this temple among them was one of the unfortunates that assisted to satiate his wrath.

The third important work with which Ictinus is reported to have been connected was the Doric temple to Apollo in the village of Bassæ, near Cotylion, in Arcadia, which was known as the temple to Apollo Epicurus (the Preserver). Pausanias speaks of this as being next to that at Tagea, the finest temple in the Peloponnesus "from the beauty of its stone and the symmetry of its proportions." This temple is still a beautiful ruin, thirty-four of the original thirty-eight columns of the peristyle standing. The structure, which in the interior possessed two rows of columns in the Ionic order, was originally admirably planned for sculptural decoration and statuary and held many fine specimens of the handiwork of Phidias and his school. Some of the carvings of the frieze and other parts of the building, which are to be seen in the British Museum, are spoken of by Lübke as the boldest and most animated compositions among all that is preserved to us of the productions of Greek art.

On the southeast slope of the Acropolis Pericles caused to be erected a building which departed broadly from the prevailing rectangular construction of the time. In was oval on plan, Doric in order, and its portico was enclosed by thirty-two columns. The most original feature of the building, however, was the roof, which was constructed in the shape of a cone and was supported by rafters formed of the masts of the ships captured in the Persian wars. From just above the cornice of the drum there projected around the entire roof a row of windows which may possibly be credited with being the archetypes of our modern dormer windows. This building was called the Odeum, or, as it is now termed, the Odeon, and was devoted to music.

Cratinus, the comic poet, who had levelled his satire at Pericles when building the "Long Walls," found in the roof of the Odeon, the idea for the cone shape of which, by the way, it is claimed the architects borrowed from the pavilion of the King of Persia, another mark for his shafts of ridicule. He sings:

"As Jove, an onion on his head he wears; As Pericles, a whole orchestra bears; Afraid of broils and banishments no more, He tunes the shell he trembled at before."

The allusion to an onion by Cratinus is explained when it is remembered that on account of the peculiar, long shape of his head the poets of Athens called Pericles _Schinocephalos_, or squill-head, from _schinos_, a squill, or sea-onion. Another version of Cratinus's satire is given thus:

"So, we see here, Jupiter Long-pate Pericles appear, Since ostracism time he's laid aside his head, And wears the new Odeum in its stead."

Music received a considerable share of attention in the education of the Greeks, and such was the influence which it is said to have possessed over the physical as well as the mental nature of the people, that it was credited with being an antidote for many of the infirmities of the body as well as the mind. The Odeon was therefore an institution of considerable importance in Athens. Here Pericles conducted in person the musical contests between the Choruses which the wealthy citizens of Athens instituted, and awarded to the winners the tripod-trophies, which as marks of special honor they were permitted to place upon their monuments. A street in Athens was devoted almost entirely to these choragic monuments, many of which were architecturally most beautiful.

The architect of the Odeon of Pericles is not known, but after its destruction by Aristion in the Mithridatic war, it was rebuilt by Ariobarzanes II, Philopator, king of Cappadocia, in the original form, who employed for the purpose the brother Roman architects, Caius and Marius Stallius, together with a third architect by the name of Menalippus, who recorded their connection with the building upon the base of a statue which they erected in honor of their patron Ariobarzanes. It is said that on certain days this later Odeon was used as a grain market.

If in the Parthenon on the Acropolis the acme of Doric magnificence was reached by Ictinus and Callicrates, there was another temple located below the Acropolis, which by many is ranked as the peer of the Parthenon, in its perfection of Doric symmetry and grace. This was the building to which allusion has already been made as another example of the genius and skill of Mnesicles, the slave-architect of the Propylæa. It was dedicated to the founder of Athens, the adventurous Theseus, and stood not only as a temple in his honor, but as a mausoleum for his ashes.

Wordsworth, whose words of praise for the Propylæa have been quoted, is also enthusiastic in his admiration of this second example of the skill of the talented Mnesicles: "Such is the integrity of its structure and the distinctness of its details that it requires no description beyond that which a few glances might supply. Its beauty defies all; its solid yet graceful form is, indeed, admirable;

and the loveliness of its coloring is such that from the rich, mellow hue which the marble has now assumed it looks as if it had been quarried not from the bed of a rocky mountain, but from the golden light of an Athenian sunset."

Although the temple of Theseus was one of the more modest Athenian temples in point of size, it has always ranked as one of the most perfect of the Attic-Doric order, and stands to-day as one of the least dilapidated among all that have existed of the beautiful edifices of ancient Greece. Indeed, as it was supposed to have been begun before the Parthenon, or in the time of Cimon, it is claimed by some writers that Ictinus took it for his model, although the Parthenon was about twice as large.

The Theseum was surrounded by columns, six at the front and rear and thirteen on either flank. It was forty-five feet wide by one hundred and four feet long. The building material was Pentelican marble, which in the course of the centuries has taken on the soft yellowish tinge which Bishop Wordsworth refers to. Ornamental sculpturing was more sparingly employed than upon the Parthenon or some of the other structures of the time, but such as was used was so judiciously handled as to give the very noblest results. The sculpturing in the metopes of the frieze and on the pronaos was the work of Phidias.

It was built after the battle of Marathon, and, it would seem, after an awakening on the part of the Athenians to that high sense of obligation toward their early hero, Theseus, which had slumbered for centuries. It was due to the Delphic Oracle that his remains were brought back to Athens from their long banishment in the island of Scyros, and given honorable burial, the son of Miltiades being selected to execute the Oracle's decree. The occasion was made one of festivity and rejoicing, and the entombment in the beautiful new temple one of sacrifice and solemnity.

In closing this brief reference to the Theseum, the graceful lines from Haygarth's Greece, which so beautifully applaud it, may well be quoted:

"Here let us pause, e'en at the vestibule Of Theseus's fane—with what stern majesty It rears its pond'rous and eternal strength, Still perfect, still unchang'd, as on the day When the assembled throng of multitudes With shouts proclaim'd th' accomplish'd work and fell Prostrate upon their faces to adore Its marble splendor. How the golden gleam Of noonday floats upon its graceful forms, Tinging each grooved shaft, and storied frieze And Doric triglyph! How the rays amidst The op'ning columns glanc'd from point to point Stream down the gloom of the long portico; Where, link'd in moving mazes youths and maids Lead the light dance, as erst in joyous hour Of festival! How the broad pediment, Embrown'd with shadow frowns above and spreads Solemnity and reverential awe! Proud monument of old magnificence! Still thou survivest, nor has envious time Impair'd thy beauty, save that it has spread A deeper tint, and dimm'd the polished glare Of thy refulgent whiteness. Let mine eyes Feast on thy form, and find at every glance Themes for imagination, and for thought; Empires have fallen, yet art thou unchang'd; And destiny, whose tide engulphs proud man Has roll'd his harmless billows at thy base."

In the brilliant galaxy of great architects and sculptors of this age, none shines more deservedly conspicuous by reason of true merit and noble purpose than Polycletus of Argos, who is remembered more as a statuary than by reason of his achievements in architecture. He exercised his art between the years 452 and 412 B.C., and, like his distinguished contemporaries, Myron and Phidias, was a pupil of the Argive sculptor, Agelades. His celebrity has been compared to that of his most famous brother pupil, Phidias, for the reason that while Phidias gave the ideal standard in the portrayal of deities, Polycletus created for all ages the perfect canon of the human form in art. This he expressed in the figure of a youth holding in his hand a spear, which was called the Doryphorus. In this figure the sculptor laid down the rules of universal application with regard to the proportions of the human body in its mean standard of height, breadth of chest, length of limbs and so on. Socrates, according to Xenophon, went so far as to place Polycletus on a level as a statuary, with Homer, Sophocles and Xeuxis in their respective arts.

A similar anecdote to that told of Phidias, when he listened to the criticisms of the public upon his colossal statue of the Olympian Zeus, is also related of Polycletus. He is said to have made two statues, one of which he perfected according to his own ideals, and the other he exhibited to the public and altered according to the suggestions volunteered. In due time he exhibited both publicly side by side. The one he had himself made was universally admired, while that which he had changed to suit the popular fancy was condemned. "You yourself," he exclaimed, "made the statue you abuse, I, the one you admire."

One of his most celebrated works was the chryselephantine statue of Hera, executed in his old age to rival the Athene and Zeus by Phidias. Strabo considered that this statue equalled in beauty those of Phidias, though it was surpassed by them in costliness and size. In the respect that Polycletus followed the Homeric description of Hera, and presented the goddess clothed from her waist down, he may be said to have followed the precedent of Phidias; in other respects, however, he drew upon his own fancy. Juno was seated upon a golden throne; her head was crowned with a garland on which were worked the Graces and the Hours; in one

hand she held the symbolical pomegranate and in the other a sceptre surmounted by a cuckoo, a bird sacred to Hera on account of having herself been changed into that form by Zeus.

As an architect Polycletus will be found as the designer of the theatre at Epidaurus, where was also located the beautiful temple dedicated to Æsculapius, and which Pausanias pronounced to be superior in symmetry and elegance to every other in Greece and Rome. It was capable of accommodating twelve thousand spectators, and its ruins, as well as those of the white marble circular Tholus, by the same artist, are still to be seen in an unusual condition of preservation.

Among the other architects who have been variously mentioned as having pursued their profession toward the close of this century, but who can hardly take equal rank with those already alluded to, may be mentioned Eupolinus, an Argive artist, who rebuilt the great Heræum at Mycenæ after its destruction by fire in the year 423 B.C., the entablature of which was ornamented with sculptures representing the wars of the gods and giants and the Trojan wars; Cleœtas, who was one of the assistant architects under Phidias, and whose chief claim to distinction is based upon his construction of the starting place in the Olympian Stadium, and Democopus Myrilla, who built the theatre at Syracuse. Vitruvius also speaks of an architect and author of about this time—namely, Silenus—who wrote on the Doric order.

It is difficult to close this chapter, in which but very superficial reference has been made to the architectural lights of the golden age of art in Greece, without glancing back at the magnificent city of Athens, the grand product of much of their creative skill, with feelings of regret that with all her numerous and noble monuments, dedicated to gods and men, there is not one that bears the imprint of its creator. We see in this glance forest-like colonnades of glittering white columns; we see the House of the Five Hundred Senators, the Tholus, the Hall of Hermæ, the Agora, the Pnyx, “where the Athenian orator spoke from a block of bare stone;” the Stoic Hall, in which philosophy was taught; the Prytaneum, where the loved laws of Solon were preserved; the Lyceum, with its hundred columns from Lydia; the Theatre of Bacchus and the Mausoleum of Tolus. We see temples innumerable, the grandest of all those to Jupiter and Theseus; but others of fascinating merit, those of Ceres and of Cybele and of Mars, and of Vulcan, of Venus, of Æacus, of the Dioscuri, of Hercules, of Diana Agrotera, of Bacchus Lunnæus, of Æsculapius, of Eumenides, and that to Glory, erected with the booty from the glorious field of Marathon, wherein stood the Venus of Phidias; and we see the Acropolis towering above all, lending other magnificent architectural triumphs to the ensemble; and although we see slabs among them “inscribed with the records of Athenian history, with civil contracts and articles of peace, with memorials of honors awarded to patriotic citizens or munificent strangers,” we find no monument, whether in the time of Pericles or later, inscribed with the name of Ictinus, or Hippodamus, or Callicrates, or the poor slave, Mnesicles, who was saved by Minerva to be forgotten by man.

[Illustration: Decoration]

FOOTNOTES:

[3] The decoration referred to was the work of the distinguished painter Protogenes.

CHAPTER VII.

LATER GREEK ARCHITECTS.

The first architect as well as artist of decided merit who arose to historic distinction at the beginning of the later Attic school, or that which followed immediately upon the school of Phidias, and one of the first to treat the Corinthian idea, then flowering into favor with originality and artistic skill, was the deserving and accomplished Scopas. Reference has already been made to this artist in connection with the temple of Diana at Ephesus, for which, it is said, he furnished the most beautiful of all the numerous columns with which that temple was enriched. This statement is made without prejudice to the great Praxiteles, who was contemporaneous with Scopas, and who excelled him as a statuary, if he did not compete with him as an architect.

A mistake of Pliny, which assigned Scopas to an earlier age, has finally been corrected, and it has been settled that the period when he exercised his art was between the years 395 and 350 B.C. Scopas was a native of Paros, a subject island of Athens, and sprung from a family which for several generations before his advent into the world had practised the plastic arts. His descendants also walked in the same artistic paths of life for many generations. Like Polycletus, with whom he is most favorably compared, the architectural side of his career was greatly eclipsed by that which displayed his genius as a sculptor.

His statues were numerous, and fortunately many of them still exist scattered in various European museums and galleries. Among such of his works considered the most interesting is the well-known series of figures representing the destruction of the sons and daughters of Niobe. In the time of Pliny these statues stood in the temple of Apollo Socianus at Rome, and it was then a question whether they were the works of Scopas or Praxiteles. In fact, many of the former's finest efforts have been attributed to the latter artist. Of this group Schlegel says: "In the group of Niobe there is the most perfect expression of terror and pity. The upturned looks of the mother, and mouth half open in supplication, seem to accuse the invisible wrath of Heaven. The daughter clinging in the agonies of death to the bosom of her mother, in her infantile innocence can have no other fear than for herself; the innate impulse of self-preservation was never represented in a manner more tender or affecting. Can there on the other hand be exhibited to the senses a more beautiful image of self-devoting, heroic magnanimity than Niobe, as she bends her body forward that, if possible, she may alone received the destructive bolt? Pride and repugnance are melted down in the most ardent maternal love. The more than earthly dignity of the features is the less disfigured by pain, as from the quick repetition of the shocks she appears, as in the fable, to have become insensible and motionless. Before this figure, twice transformed into stone, and yet so inimitably animated—before this line of demarcation of all human suffering the most callous beholder is dissolved in tears."

Another highly esteemed work of Scopas, which Pliny says stood in the shrine of Cneius Domitius in the Flaminian circus in Rome, represented Achilles conducted to the island of Leuce by the divinities of the sea. It consisted of figures of Neptune, Thetis and Achilles surrounded by Nereids sitting on dolphins and other large fish, and attended by Tritons and sea monsters. In the opinion of Pliny, these figures alone would have been sufficient to have immortalized the artist, even if they had cost the labor of his entire life.

His statues of Venus, are, after all, perhaps the most remarkable of his works in sculpture. One of these statues, if not the original, is supposed to have been the prototype of one of the most celebrated and beautiful portrayals of that charming deity in the world to-day. Another to which Pliny gives particular prominence was that in which the goddess is presented nude and which was found in the temple of Brutus Callaicus in Rome. This statue, he adds, "would have conferred renown upon any other city, but at Rome the immense number of works of art and the bustle of daily life in a great city distracted the attention of men." It is probably this work of art, which is thought by some to have been superior to that by Praxiteles, which, with some modifications, is credited with being the model after which Cleomenes fashioned the celebrated Venus de Medicis. Pausanias and Pliny mention also other portrayals of Venus by Scopas, but it is left to Waagen and some other critics to ascribe the celebrated statue of Aphrodite, in the Louvre in Paris, and known as the Venus de Milo, to this great sculptor and architect.

It is foreign to the purpose, however, to devote too much space to this side of the art life of Scopas, but in treating of his connection with the magnificent mausoleum which Artemesia erected at Halicarnassus, to her husband, Mausolus, king of Caria, it will be argued doubtless that the work of this artist on that famous mortuary monument, which ranked as one of the seven winders of the world, was more in the line of a decorative sculptor than of an architect.

In this undertaking Scopas was associated with three other architectural sculptors—namely, Bryaxis, Timotheus and Leocarus—all of whom were Athenians. Each took as his special work the decoration of one side of the building, Scopas choosing the east or principal façade. The north and south sides had a width of about sixty-three feet; the east and west were not quite so wide.

Before outlining further the principal characteristics of the building, it is only fair to say that the professional architects to whom is due the credit for the plan of the structure were Phileus, an Ionian whose name Vitruvius spells in a variety of ways, and Satyrus, whose native city is not given, but who, according to the same authority, wrote a description of the mausoleum. Phileus was also an author on architecture, having written a volume on the Ionic temple of Athene Polias at Priene, of which he was the designer, and which was one of the most renowned buildings in Asia Minor, and a treatise on the mausoleum, which was also located in that part of the globe. As for Satyrus, whatever may have been the other public buildings of which he was the architect, there is no record.

The mausoleum had a total height of one hundred and forty feet, and in general appearance combined orientalism in tomb-structure with the perfections of Grecian architectural grace and elegance. The tomb was contained within a rectangular substructure. Above was an Ionic peristyle temple with nine columns on each side and eleven at the ends. The frieze was elaborately carved and decorated, and the roof, which was pyramidal in form, gave the oriental cast to the entire building. At the apex of the roof was a colossal marble quadriga, in which a statue of the deceased king Mausolus appeared. It is said that in the sculptures and carvings of the different sides the respective artists strove to rival each other, and that although queen Artemesia died before the tomb was finished the four artists were so interested and absorbed in their work that they determined to complete it at their own risk.

Up to the twelfth century after the Christian era this grand tomb stood in a fairly good state of preservation, but soon after fell to pieces, and was used from that time as a quarry by the Knights of St. John, from which they took stone for the castles they built on the site of the old Greek Acropolis. Later still much of the marble was taken to repair their fortifications, and it is even said to make lime, showing to what ignominious uses the very greatest of architectural glories may finally come. However, some of the carvings have been redeemed from the fortification walls and unearthed from other places in Budrun, the modern Halicarnassus, to find a final resting place, let it be hoped, in the British Museum. These rescued pieces of marble, of which there are perhaps sufficient to reconstruct a quarter of the whole frieze, though they are not continuous, are pronounced by competent judges to be specimens of the work of the different artists, but there is no means of determining which of them, if any, came from the chisel of Scopas.

The temple of Athene Alea at Tegea in Arcadia, often a sanctuary for fugitives from Sparta, was an architectural creation of Scopas, which it would appear belonged to him exclusively. Of all the temples in the Peloponnesus this is said by Pausanias to have been the largest as well as the most magnificent. That observant traveller, however, must have been carried away somewhat by his enthusiasm over its architectural attractions in ascribing to it such great size, as its dimensions were not more than one hundred and sixty-four by seventy feet, being very much smaller than other Grecian temples.

The temple which Scopas built was not the first to the goddess to occupy the same site, but followed a very much more ancient one, which was destroyed by fire in the year 394 B.C. The tendency to introduce the Corinthian order, which followed after the Peloponnesian wars, and which continued to grow as Greece became more and more intermixed with Roman ideas, is here early displayed. The columnar arrangement of the temple was unusual; for the outside the Ionic style was used, there being six columns at each end and fourteen on the sides; but on the inside the Doric order was employed surmounted by the Corinthian. Both pediments of the building were sculptured by Scopas or from his designs under his immediate supervision. The pediment over the front portico portrayed the chase of the Calydonian boar, and that in the rear the battle of Telephus with Achilles; both being, according to Pausanias, very animated compositions. The statue of the goddess Athene Alea, contained in the cell, was carried off by the Emperor Augustus and placed at the entrance of his new forum in Rome. Some fragments of the pedimental sculptures have been discovered and placed in the British Museum.

To Scopas, in co-operation with Praxiteles, is also attributed the graceful and beautiful Choragic monument of Lysicrates, at one time called “the lantern of Demosthenes,” from the mistaken supposition that the great orator used it as a study—a very strange use when it is remembered that the little structure possessed neither doors nor windows. In its day this monument was the pride of the street of Tripods, and it still stands one of the best preserved evidences of the taste and skill of its designers.

In this monument the Corinthian style of decoration is displayed in its perfection of grace, better, perhaps, than in any other structure of that early time which is known to us. Stuart describes it as follows: “The colonnade was constructed in the following manner: six equal panels of white [Pentelic] marble, placed contiguous to each other on a circular plan, formed a continued cylindrical wall, which of course was divided from top to bottom into six equal parts by the junctures of the panels. These columns projected somewhat more than half their diameters from the surface of the cylindrical wall, and the wall entirely closed up the intercolumination. Over this was placed the entablature and the cupola, in neither of which any aperture was made, so that there was no admission to the inside of this monument, and it was quite dark.”

The “flower,” or crowning ornament of the monument, was a particularly graceful and beautiful arrangement of acanthus leaves and volutes, and the roof was worked out with great delicacy and originality in the form of a thatch of laurel leaves and Vitruvian scrolls. If there was any apportionment of the work on this monument between Scopas and Praxiteles, it would be interesting to know what it was.

Of the other architectural sculptors associated with Scopas in the adornment of the tomb of Mausolus none is mentioned as having had any other connection with architecture in a similar way, but all were statuaries of distinction and high merit, who executed works in marble or bronze, or both, that gave them prominence in their art. Among other works by Bryaxis were five colossal statues in the island of Rhodes, of which the celebrated “colossus of Rhodes,” however, was not one, and also a statue of Apollo, which was destined for the temple of Daphnis near Antiochus. The story is related that Julian the Apostate wished to render to this figure peculiar worship and homage, but was prevented from so doing by a miraculous destruction of the temple and statue by fire. Clement of Alexandria asserts that Bryaxis was the artist of many works ascribed to Phidias.

As to the share which Timotheus took in the decoration of the mausoleum there is dispute among the Greek authorities, some ascribing his work to Praxiteles; but there does not seem to be any just foundation for the supposition that the sculpturing on the

south side of the tomb was by any other hand than that of Timotheus. As one of the great statuaries of the later Attic school he was also among the most prominent, his figure of Artemis being deemed worthy to be placed by the side of the Apollo of Scopas, and the Latona of Praxiteles in the temple which Augustus erected to Apollo on the Palatine. Other statues of conspicuous merit are also ascribed to him by Pausanias and Pliny.

Leochares, the last of the quartette, was also inferior only to Scopas and Praxiteles in his school of art. He was particularly skilful with portrait-statues, the most successful of which were those of Philip of Macedon, Alexander his son, Amyntas, Olympias and Eurydice, all of which were made of ivory and gold, and were placed in the Phillippeion, a circular building in the Altis at Olympia, erected by Philip in celebration of his victory at Chæroneia. But the _chef d'œuvre_ of Leochares was a bronze statue of the rape of Ganymede. Pliny says of this work that the eagle seemed to be sensible of what he was carrying and to whom he was bearing the treasure, taking care not to hurt the boy through his dress with his talons. The original statue was frequently copied both in marble and on gems, several of which copies are still extant: one in the Museo Pio-Clementino, another in the library of St. Mark in Venice, and still another figures in Stuart's Athens, as an alto-relievo found among the ruins of Thessalonica.

CHAPTER VIII.

THE ALEXANDRIAN ERA AND ROMAN SPOLIATION.

That epoch in the art life of the Hellenic people associated with the influences arising out of the career and conquests of Alexander the Great, which we have now reached, was one scarcely inferior in interest to that of the time of Pericles. Overflowing as was the great Macedonian leader's love of art and great as was his ambition to leave behind him lasting monuments that should fittingly stand for the artistic culture of his time, still, for reasons arising partly out of his own career and partly from the ever-changing impulses of human feeling and taste, the art culture of his time must bow to the superiority of that of the time of Pericles, if, in respect to those other features of his leadership and accomplishment, to which history gives a superior rank, his genius is eclipsed by none in the chronicles of civilization.

Alexander's short life, so active in conquest and war, and so much of it passed away from European associations or even the influences of colonial Greece, necessarily gave him little time for indulgence in the arts at home, while it permitted him to manifest it to some considerable extent in founding cities and rearing temples in foreign lands. To this self-imposed banishment, accompanied, as it was, by large armies brought from Greece and her colonies, and the intermixing of her people with foreigners of new tastes and habits of mind, may be attributed that change of art feeling at home which began to assert itself about this time. On the other hand, however, its effect was beneficial to the conquered countries in introducing a more elevated art standard than had existed within them before.

Personally, Alexander manifested a keen appreciation of the arts; whether founded upon the same sincerity as that which appeared more natural to the character of Pericles is a question; but we find that Praxiteles, Lysippus and Apelles, the great artists of his time, were no less publicly honored or more highly flattered than were Phidias or Polycletus in the days of Pericles. It is related as an evidence of Alexander's enthusiasm for art, that he compensated Apelles for his celebrated portrait of him by ordering that the artist's reward should be _measured out in gold_ instead of being _counted_, an order which perhaps quite as much illustrated the theatrical impulses of which he could be guilty as the calm expression of a genuine appreciation.

Even had Alexander been spared, and had returned to Greece to continue a long life of usefulness to his people, instead of having been cut off in his prime at Babylon, although he might have done much more for art than he did, still he could not have accomplished for it what had been attained by Pericles. This may be argued from his birth, schooling and the stronger trend of his mind, which led in very different directions. The Macedonian had not certainly the traditions of art culture in his veins, as was the case with the more polished Athenian, and being fonder of the dazzlement of pomp and show, natural to a leader who from infancy had been almost continuously associated with the accoutrements and regalia of armies, it is not likely that whatever he might have accomplished for art more than that which he actually did, would have manifested that purity of ideal, as well as refinement of execution which so marked and dignified the work of Pericles.

As there is always some time which must elapse before the tide, having reached its flood, turns once more to slowly ebb, so was there a time to be expressed in a few years when the plastic arts of Greece, reaching their highest development in the age of Pericles, remained stationary, before ebbing away to so-called Roman degeneracy, and the mixed influence of various

comparatively uncultured nationalities.

The Alexandrian epoch marks the beginning of this turning-point. The decadence took almost as many successive generations to the time when Corinth was sacked by the Romans in 146 B.C., and the Italian soldiers cast their dice upon the pictures of Aristides, as it had taken to advance in the earlier ages of Greece, to the time when the chryselephantine statues of Zeus and Athene, by Phidias, were the recognized perfect standards of godlike majesty and beauty, and the Doryphorus of Polycletus was accepted as the criterion of human grace and proportion.

Of course the standard by which the perfection of architectural dignity and purity can be measured is largely one of individual taste and preferment, as is sometimes evidenced by the conflicting judgments of the best critical authorities, but if we accept the conclusions of centuries of the highest criticism, we must be prepared to concede that the arts to which we refer reached their zenith as stated. However, the expression, Roman degeneracy, is much too severe a one, if taken in other than a comparative sense; for, whatever Grecian architecture may have lost in ideal æstheticism by reason of Roman interference, it must be granted the Romans that their own evolution in the appreciation of the arts and the accomplishments of architecture resulted in a magnificence which, when compared with our own time, gives them rank second only to the Greeks, from whom they borrowed so much, and whom they did not scruple to rob of nearly all their portable art treasures. “Among the innumerable monuments of architecture constructed by the Romans,” says Gibbon, “how many have escaped the notice of history, how few have resisted the ravages of time and barbarism! And yet even the majestic ruins that are still scattered over Italy and the provinces would be sufficient to prove that those countries were once the seat of a polite and powerful empire. Their greatness alone or their beauty might deserve our attention; but they were rendered more interesting by two important circumstances, which connect the agreeable history of the arts with the more useful history of human manners. Many of these works were erected at private expense, and almost all were intended for public benefit.”

But the burnishing of the Romans to the high polish which they finally attained in the arts was a slow process, and one which met with many interruptions, according as their rulers were individually affected by a love of the artistic—a fact which in itself would show that art was not an inherent quality in the Roman nature to the like degree that it was in that of the Greek. To admire the Grecian æsthetic culture was at first considered an evidence of effeminacy, and even Cato exclaimed against the arts not seventeen years after the taking of Syracuse. The Consul Mummius, in 146 B.C., some hundred years later, after the battle which resulted in the capture of Corinth, proved very conclusively that he had very little appreciation of the merit of the treasures he found there, for he not only destroyed a great many, but shipped to Rome many more, for the simple reason that, recognizing how much they were prized by the Corinthians, he wisely saw that they might be useful in Rome. This sacking of Grecian cities was quite popular, and the Roman generals, in their conquests, seemed to strive which should bring away to Rome the greatest number of statues and pictures. The elder Scipio despoiled Spain and Africa, Flamius Sylla and Mummius exported shiploads of the art of Greece, Æmilius despoiled Macedonia, and Scipio the younger, when he destroyed Carthage, transferred to Rome the chief ornaments of that city.

In fact, the Roman generals were remarkable as art pilferers, using the spoils not alone to adorn their public buildings and institutions, but in some instances their private houses and palaces as well. It is related of Scaurus that he embellished his temporary theatre, erected for a few days’ use, with no less than three thousand statues. He also returned to Rome with all the pictures of Sicyon, one of the most eminent schools of painting in Greece, on a pretence that they would compensate for a debt due the Roman people. From this habit of drawing on foreigners it finally came to pass that private citizens took the fever and entered upon the luxury. None was earlier in the field than the Luculli, particularly Lucius Lucullus. Julius Cæsar was personally a great collector, his hobby being gems, while his successor, Augustus, displayed an acute interest in Corinthian vases.

Augustus did much for the architectural adornment of Rome, and his much-quoted remark to the effect that he found Rome a city of bricks and left it one of marble, was, to a great degree, true. In fact, Augustus manifested an æsthetic nature in many respects. Spence says, speaking of the arts, that “the flavor of Augustus, like a gentle dew, made them bud forth and blossom; and the sour reign of Tiberius, like a sudden frost, checked their growth, and killed all their beauties.” Men of genius were flattered, courted and enriched under Augustus, as they were some four hundred years’ earlier in Athens under Pericles, with the result that Vergil, Horace, Ovid and other poets of the greatest merit sprung forward. Rome became in this age the seat of universal government also, its wealth was enormous, its architectural decorations numerous and splendid, and even its common streets were decked with some of the finest statues in the world. Other great architectural epochs of Rome were those of the time of Trojan and Hadrian. But as evidence of the intermittent character of her art development, very little was realized, as very little could be expected under the reigns of such monsters as Tiberius, Caligula and Nero. To Nero, however, we must accord some little credit in having built a very

remarkable architectural composition, although undertaken for no public benefit, but to satisfy his own profligate vanity. His “Golden Palace,” built under the direction of the architects Celer and Severus, the most eminent of their time, was ranked as the most “stupendous” structure of its kind in all Italy. The palace was built after the conflagration during which Nero is supposed to have amused himself with a violin. Tacitus tells us that it was ornamented in every part with “pearls, gems and the most precious materials,” especially gold, which was used in reckless profusion. In the centre of a court adorned with a portico of three rows of lofty columns, each row a mile long, stood a colossal statue of that colossal sensualist and wicked monarch, which was one hundred and twenty feet in height. Vespasian tore down the whole of this piece of architectural vanity, restored the land which it had occupied and by which it was surrounded to the people from whom it had been stolen, and erected in its place the great public Coliseum and the magnificent Temple of Peace.

In alluding to the public palaces of amusement, Curio, a Roman Prætor, some few years before the Christian era, is said to have built two wooden theatres close together, which turned on pivots. During the day they were turned away from each other, and different plays were performed in each; then, with all the spectators, they were turned together, forming an amphitheatre in which combats took place. The zeal of the Roman architects to win popular favor by something novel and striking was often very great. In Pompey’s theatre water was made to run down the aisles, between the seats, in order to refresh spectators in the heat of summer.

But that the Roman architects were not always as careful in the inspection of the buildings under their supervision as they should have been, and, like some of our modern architects, permitted their works to be used when in an unsafe condition, is shown from the unfortunate catastrophe which resulted in the unexpected tumbling to pieces of the theatre of Fidenæ near Rome. This accident happened in the reign of Tiberius, and the name of the architect who suffered banishment for his neglect was Attilius. The theatre was built of wood, and out of fifty thousand people who were injured in the collapse twenty thousand are said to have died.

Of all the Roman emperors none is more interesting to the student of Grecian architecture than Hadrian, who was a great admirer of Greece, seeking to introduce the Hellenic institutions and modes of worship in Rome, as well as the art, poetry and learning of Greece. He also undertook to restore Athens, which had suffered greatly during the four or five hundred years which had elapsed between his time and that of Pericles, to something of her former architectural grandeur. Pope’s couplet might have been Hadrian’s inspiration:

“You, too, proceed! make falling arts your care, Erect new wonders and the old repair.”

Indeed, he caused to be inscribed upon the Arch of Honor, which he erected in Athens, after the restoration, two inscriptions which, if not in the best of taste, were in harmony with their author’s self-love, of which he possessed no inconsiderable share. Upon that side of the arch which faced the ancient city he wrote: “This is Athens, the old city of Theseus,” and on that which fronted upon the new city of his restoration and adornment was inscribed: “This is the city of Hadrian, and not of Theseus.” In other words, the visitor was expected to make his own comparison and perhaps draw the conclusion intimated that Theseus was not, after all, to be compared with the Roman Hadrian.

Hadrian’s particular penchant was architecture, and his predominant vices were vanity and jealousy, both of which were manifested in his practice of that art. The magnificent villa which he erected at Tiber, where he spent his declining years, and the ruins of which even now cover a space equal to a large town, would indicate this, as well as the grandiose mausoleum which towered high above the banks of the Tiber at Rome, and which is now depleted of much of its statuary and ornamentation, the Christian church of Saint Angelo. The treatment which he accorded Trajan’s great architect, the accomplished Apollodorus, is still another evidence of his vanity.

Hadrian, like Louis I. of Bavaria, found delight in practising personally the profession of architecture, and drew plans of buildings, which the people thought was unbecoming a prince. Possibly this objection was raised to discourage their ruler rather than the more truthful one that his plans were not up to the high standard of his time. However that may be, he insisted upon their being executed, and it is said was rather pleased if the architects found fault with them. But this was not the case with Apollodorus, whether because of what he had accomplished for his predecessor Trajan, or because of professional jealousy.

Apollodorus was the architect of the Trajan column, composed of only twenty-four stones, although one hundred and twenty-eight Roman feet in height, and the square which surrounded it, considered the most beautiful assemblage of buildings then known. The relief carvings which were wound spirally around the Trajan column like a ribbon, represented the incidents of the expedition against the Darians. The column supported a statue of Trajan, which Pope Sextus V. substituted for one of Saint Peter. A greater absurdity can hardly be conceived than that of placing a peaceful apostle over the warlike representations of the Dacian war.

Apollodorus was also the architect and engineer of the great bridge which stretched across the Danube in lower Hungary, which was formed of twelve piers and twenty-two arches, said to have been the grandest use of the arch in such works. Each arch was sixty feet wide and one hundred and fifty feet high. The total height of the bridge was three hundred feet and its length a mile and a half. Hadrian destroyed this magnificent work, some say through fear of its use by barbarians, others through jealousy. Perhaps the circumstances attending the death of Apollodorus would point to the second reason as the true one.

Hadrian had made the drawings of the double temple of Venus at Rome, which he submitted to Apollodorus, doubtless for his commendation rather than his criticism. The architect saw at a glance that the sitting figures of the two goddesses, Roma and Venus, which the Emperor had introduced in the little temple, were out of proportion, and so large that if they stood up they would bump their heads against the roof, if they did not take it off entirely. He called the Emperor's attention to this fact with the result that Hadrian became very angry, or pretended to be so, and Apollodorus lost his head for his frankness.

The favorite architect of Hadrian was Detrianus, to whom he entrusted many of his most important undertakings. We find that he restored the Pantheon of Agrippa, the Basilica of Neptune, the Forum of Augustus and the Baths of Agrippina. As original works he designed the Mausoleum of Hadrian, to which we have already alluded; the bridge of Ælius, ornamented with its covering of brass, and supported by its forty-two columns, terminating at the top with as many statues, and the villa at Tivoli. He also erected many structures for his royal patron in Gaul, among which was the Basilica Plotina, the most superb building in that country, and again other buildings in England. The Roman wall from Eden in Cumberland to Tyne in Northumberland, a distance of eighty miles, which was built as a defence against the Caledonians, is attributed to Detrianus. In Greece he embellished the famous temple of Jupiter Olympus, and in Palestine he rebuilt Jerusalem, erected a theatre and various pagan temples out of the stone from the Jewish temples, and completed his sacrilege there by placing a statue of Jupiter on the spot where Christ rose from the dead, and one of Venus on Mount Calvary. A feat, however, which has perpetuated his fame quite as much as any other of his professional achievements was the removing of the colossal bronze statue of Nero, which stood in the court of the "Golden Palace." This difficult task he is said to have accomplished without changing the erect posture of the huge figure, which, it will be remembered, was one hundred and twenty-eight feet high, by the assistance of twenty-four elephants.

In returning once more to the Greek architects who have been left, while a rather garrulous ramble has been made into the architectural personality of Rome, it may be well not to attempt to do so at once, but to pause for a moment, since we are so far from the chronology of our subject, while the reader makes the acquaintance of two Hellenic artists who, in the time of Quintius Metellus, 147 B.C., found professional employment in Roman territory.

Metellus was one of the first Romans to favor magnificent architecture in his home capitol, and with the booty gathered in his Macedonian campaigns he erected two temples in Rome, said to have been the first temples built of marble in that city, one of which was dedicated to Jupiter Stator, and the other to the white-armed Juno. The interiors were profusely ornamented with the works of the great Grecian masters, Praxiteles, Polycletus and Dionysius figuring largely.

The names of the architects which Metellus brought or imported from Greece for this work were Saurus and Batrachus, who may possibly have been Ionians, inasmuch as they employed the Ionic order. These temples were restored in the Corinthian style, under Augustus, two hundred years later, by Hermodorus of Salamis, who was also the architect of the temple of Mars in the Flaminian Circus.

It is told of Saurus and Batrachus that they were so much pleased with their work that they asked for no reward other than the privilege of having their names inscribed on the temples. But as this honor was denied them, they resorted to expedient to effect the same end. As the name Saurus stood for lizard and Batrachus for frog, they carved lizards and frogs on the temples, and were comparatively satisfied. A rather absurd mistake occurred in respect to these two temples after they were completed. It seems that nothing remained to be done but to add the statues of Jupiter and Juno to each respectively; but by some strange oversight the figure of Jupiter was erected in the house of Juno, and that of Juno before the shrine of Jupiter. However, as the two deities were rather closely connected by marriage, the mistake was conveniently attributed to a whim of the gods and was not remedied.

CHAPTER IX.

THE ALEXANDRIAN ARCHITECTS.

The boldest, most ingenious and original architect who found favor in the sight of Alexander the Great was undoubtedly Dinocrates, who, like his august patron, was also a Macedonian, and to whom an allusion has already been made in connection with the temple of Diana at Ephesus.

[Illustration: DINOCRATES BEFORE ALEXANDER THE GREAT.]

His very introduction into the notice and attention of his distinguished fellow-countryman would tend to prove that Dinocrates was a person of expediency, if nothing else. Let Vitruvius tell the story: “Dinocrates, the architect, relying on the powers of his skill and ingenuity, while Alexander was in the midst of his conquests, set out from Macedonia to the army, desirous of gaining the commendation of his sovereign. That his introduction to the royal presence might be facilitated, he obtained letters from his countrymen and relations to men of the first rank and nobility about the king’s person, by whom, being kindly received, he besought them to take the earliest opportunity of accomplishing his wish. They promised fairly, but were slow in performing, waiting, as they alleged, for a proper occasion. Thinking, however, that they deferred this without just grounds, he took his own course for the object he had in view. He was, I should state, a man of tall stature, pleasing countenance and altogether of dignified appearance. Trusting to the gifts with which nature had endowed him, he put off his ordinary clothing, and, having annointed himself with oil, crowned his head with a wreath of poplar, slung a lion’s skin across his left shoulder, and, carrying a large club in his right hand, he sallied forth to the royal tribunal, at a period when the king was dispensing justice.

“The novelty of his appearance excited the attention of the people, and Alexander, soon discovering with astonishment the object of their curiosity, ordered the crowd to make way for him, and demanded to know who he was. ‘A Macedonian architect,’ replied Dinocrates, ‘who suggests schemes and designs worthy your royal renown. I propose to form Mount Athos into the statue of a man holding a spacious city in his left hand and in his right a huge vase, into which shall be collected all the streams of the mountain, which shall thence be poured into the sea.’

“Alexander, delighted at the proposition, made immediate inquiry if the soil of the neighborhood were of a quality capable of yielding sufficient produce for such a state. When, however, he found that all its supplies must be furnished by sea, he thus addressed Dinocrates: ‘I admire the grand outline of your scheme, and am well pleased with it; but I am of opinion he would be much to blame who planted a colony on such a spot. For as an infant is nourished by the milk of its mother, depending thereon for its progress to maturity, so a city depends on the fertility of the country surrounding it for its riches, its strength in population, and not less for its defence against an enemy. Though your plan might be carried into execution, yet I think it impolitic. I nevertheless request your attendance upon me, that I may otherwise avail myself of your ingenuity.’ From that time Dinocrates was in constant attendance on the king, and followed him into Egypt.”

Vitruvius does not explain why it was that Dinocrates singled out the curious costume, or rather lack of costume, which he did to attract the attention of Alexander. It was, in fact, the garb of an athlete. Among the early Greeks a professional athlete was regarded as a person of social distinction, and if a particularly successful one, a personage to whom a statue might be erected, or upon whom other honors might be conferred. In fact, the uniform of an athlete was, as a rule, a passport to the best society. Dinocrates undoubtedly knew this, and as he was seeking an _entré_ into the very highest court circles, he took not an extraordinary method of gaining it.

Mount Athos, which the architect proposed to take as a basis for what was really to be a gigantic statue of Alexander himself, was a pyramidal mountain, at the extreme end of the Acte peninsula, having an altitude of 6780 feet, and crowned with a cap of white marble, which Dinocrates undoubtedly had in mind to utilize for a helmet. The country surrounding the mountain was remarkable for its rural beauty, its woods and ravines, and its people for their longevity. No wonder that Alexander did not wish to disturb this peaceful neighborhood.

Alexander Pope, who has given us an admirable rhymed translation of the songs of Homer, seems to have been greatly impressed with the practicability of this remarkable idea of Dinocrates. Spence, the author of “Polymetis,” was once discussing the incident which Vitruvius relates with Pope, remarking that he could not see how the Macedonian architect could ever have carried his proposal into execution, when Pope at once replied: “For my part, I have long since had an idea how the thing might be done; and if anybody would make me a present of a Welsh mountain and pay the workmen, I would undertake to see it executed. I have quite formed it sometimes in my imagination: the figure must be in a reclining posture, because of the hollowing that would be necessary, and for the city’s being in one hand. It should be a rude, unequal hill, and might be helped with groves of trees for the eyebrows, and a wood for the hair. The natural green turf should be left wherever it would be necessary to represent the ground he reclines

on. It should be contrived so that the true point of view should be at a considerable distance. When you are near it, it should still have the appearance of a rough mountain, but at a proper distance such a rising should be the leg, and such another an arm. It would be best if there were a river, or rather a lake, at the bottom of it, for the rivulet that came through his other hand to tumble down the hill and discharge itself into the sea."

Mrs. Baillie, in her "Tour on the Continent," has also a comment to make on this proposition of Dinocrates and recalls the fact that a somewhat similar idea was advanced to Napoleon I. "It is somewhat singular," she says, "that Mr. Pope should have thought this mad project practicable, but it appears that there are still persons who dream of such extravagant and fruitless undertakings. Some modern Dinocrates had suggested to Bonaparte to have cut from the mountain of the Simplon an immense colossal figure, as a sort of Genius of the Alps. This was to have been of such enormous size that all the passengers should have passed between its legs and arms in a zigzag direction."

Another ingenious conception is attributed to Dinocrates in respect to the temple of Diana, which he erected in the city of Alexandria for Ptolemy Philadelphus, in memory of the sister-wife of that potentate, Arsinoë. This relationship, by the way, is said to have been the first ever formed, although it became quite common later in the time of the Ptolemies. Arsinoë was much beloved by her husband, who not only called an entire district in Egypt, Arsinoites, after her, but also gave her name to several cities within his realm. Her features are still preserved to us upon coins struck in her honor, and which represent her crowned with a diadem.

When Dinocrates received the commission to erect a temple to so highly esteemed and devotedly remembered a queen, he apparently set his ingenuity to work to give birth to a novelty that should not only please the king, but astonish his subjects. It finally matured in a proposition to roof the proposed temple with loadstones, in order that they might attract into the air an iron statue of Arsinoë. As the figure of the queen would thus appear suspended in the air without any apparent mundane reason, the inference could be drawn that it was by the divine will. Some authorities say that the entire inner walls of the temple were to have been lined with loadstones, so that the statue might appear suspended in the very centre of the cell, touching nothing. Fortunately, both Dinocrates and Ptolemy died before the project could be executed, otherwise they might have been witnesses to the miserable failure such a chimerical fancy must have proved if attempted, as any modern electrician will attest.

When at Ectabana with Alexander, Dinocrates had still another opportunity to display his resourceless originality, in directing the obsequies of Hephæstion, which were of a most extraordinarily elaborate nature, costing, it is recorded, 12,000 talents, or what would be equivalent to over $1,300,000. Hephæstion was a Macedonian and a close and warm friend of Alexander, accompanying the young king in a military capacity throughout most of his early foreign campaigns. So attached was Alexander to his friend that he not only showed him many marks of his personal esteem, but bestowed upon him in marriage Drypetis, the sister of his own bride, Statira. At Ectabana Hephæstion was attacked by a fever which had a fatal termination after an illness of seven days. Alexander's grief over the loss of his brother-in-law was violent and extreme, and is said to have found vent in the most extravagant demonstrations. He ordered general mourning throughout the entire empire, and Dinocrates to build a funeral pile and monument to him in Babylon, where the body had been conveyed from Ectabana, at a cost of $1,000,000.

But the richest occasion afforded Dinocrates to display to the fullest his great talents and genius was the laying out of the city which Alexander determined to found in Egypt, and which, bearing the conqueror's name, was destined to become the centre of the commercial activity of the new empire. This great city, which rapidly grew to be one of the most populous of ancient times, and which has maintained, if not its original share of industrial supremacy, at least an important existence throughout the ages that have elapsed from its nativity to the present time, we cannot resist thinking was probably as much the inspiration of Alexander's favorite architect, realizing its professional possibilities, as it was that of Alexander himself. Pliny informs us that Dinocrates died before he could give the city the full proportions which he had planned, but not certainly until its principal features were executed.

Strabo, the "squint-eyed" geographer, gives a more circumstantial account of the planning of the new city by Dinocrates and his powerful and ambitious patron. It must have been indeed an interesting sight to see the two Macedonians upon the plane which was selected for the site of the city, laying out the streets and avenues, marking the run of the walls that were to surround it, locating the different sites where were to stand the public buildings, parks, palaces and temples, and perhaps disputing and arguing over the questions that arose, as two such dominant intellects might very naturally be supposed to do.

The basis of the plan were two main streets crossing each other at right angles, each one hundred feet wide and lined with colonnades. The other streets were to run parallel to these. Near the centre of the proposed city was to be clustered the public buildings, the Museum and the Serna, which subsequently contained an alabaster coffin in which rested the remains of Alexander.

Alabaster, which the Greeks obtained from Thebes, was much used for mortuary purposes, as well as for columns and statues.

Plutarch also describes the planning of the city as follows: “As chalk-dust was lacking, they laid out their lines on the black, loamy soil with flour, first swinging a circle to enclose a wide space, and then drawing lines as chords of the arc to complete with harmonious proportions, something like the oblong form of a soldier’s cape. While the king was congratulating himself on this plan, on a sudden a countless number of birds of various sorts flew over from the land and the lake in clouds, and, settling upon the spot, devoured in a short time all the flour, so that Alexander was much disturbed in mind at the omen involved, till the augurs restored his confidence again, telling him the city he was planning was destined to be rich in resources and a feeder of the nations of men,” a prophecy which proved its truth in the fulfilment.

Dinocrates was not, however, the only architect employed in laying out so large a city, as might naturally be supposed, although he was, of course, the governing one. How many more there were it would be difficult to say, but there is record at least of two others, both probably employed by the rapacious and unscrupulous Cleomenes, whom Alexander left in Egypt as hyparch under Ptolemy Philadelphus. Olynthius is the name given of one of these architects and Parmenion of the other. The latter was entrusted more particularly with the superintendency of the works of sculpture, especially in the temple of Serapis, which, by the way, came to be called by his name, Pharmenionis. Bryaxis is also credited with statuary work there.

Upon the island of Pharos, which was joined to the city of Alexander by a wide mole, about three-quarters of a mile long, in which were two bridges over channels communicating between the eastern and western harbors, was built by Ptolemy Soter and his son in the year 282 B.C., a most famous lighthouse and a very glorious ancestor of such guardians of the coast as exist to-day.

This lighthouse was planned by Sostratus, another remarkable character in the architectural roll of honor of those early times. He was a native of Cnidus, a town in Caria in Asia Minor, to the south of Ionia and Lydia, celebrated also as the birthplace of several other men who rose to distinction in the early days of the Greek colonies as mathematicians and astronomers. Cnidus was almost equally remarkable in its possession of two famous works of the statuary’s art: one the figure of a lion carved from a single block of Pentelic marble, ten feet long by six feet wide, which was executed to commemorate the great victory of Caria; the other a statue of Venus by Praxiteles, which occupied one of the three temples to the goddess in that city. It is said that Nicomedes of Bithynia was so fascinated by the rare beauty of this figure that he offered to liquidate the debt of Cnidus, which was by no means a small one, if the citizens would cede the statue to him. They refused, however, to part with it at any price, esteeming it one of the glories of their city. Cnidus contained many beautiful architectural monuments, the ruins of which are still prominent.

Sostratus, the architect, was the son of Dexiphanes, and must not be mistaken for any one of several other artists of the same name who are conspicuously mentioned by the early writers. His first fame was acquired through his connection with the celebrated so-called hanging gardens which he built in his native country. They consisted of a series of porticos or colonnades supporting terraces, surrounding an enclosure, possibly the Agora of the city, and served as a promenade for the inhabitants. Pliny says that Sostratus was the first to erect anything of the kind. This statement may be excused, either because the hanging gardens of Sostratus differed widely from the well-known ones of Babylon, which antedated them by several hundred years, or because Pliny forgot for a moment those of Semiramis.

Strabo, who was probably right in his judgment, thinks that the greatest of Sostratus’s works was the towering lighthouse at Pharos, which he built at a cost of about $900,000, although from its size it would seem that it should have cost more. This colossal tower at once took its place among the seven wonders of the ancient world. It pierced the sky at a height of four hundred and fifty feet, or about one hundred and seventy-five feet above the towers of the Brooklyn Bridge and fifty feet above the torch with which the Goddess of Liberty illuminates the harbor of New York. But its height alone was not more marvellous than its other proportions, which were upon a most extravagant scale. The ground story was hexagonal, the sides alternately convex and concave, and each was one-eighth of a mile in length. The second and third stories were each of the same form, although decreasing in size; the fourth was square, flanked by four round towers, and the fifth or top story was circular. A grand staircase led through each story to the roof of the building, where every night massive fires were lighted, revealing the sea for a hundred miles.

When we consider that this colossal building was made entirely of wrought stone—when we reflect upon the amount of labor involved in its construction, its ponderous size and dizzy altitude—we cannot but marvel at the extraordinary breadth of conception manifested by its architect and builders and the tenacity with which they must have held to the completion of their huge undertaking. It is not to be wondered at that when Sostratus stood off and contemplated this mighty product of his imagination and genius, after its completion, he should have been actuated with the desire to have his name associated with it for all time, and

indelibly engraved somewhere upon its imperishable stone. The story is that Sostratus engraved an inscription upon one of the stones which he afterward covered with cement, and on the cement he inscribed the name of Ptolemy, knowing that in time the cement would decay and leave exposed the hidden writing upon the stone beneath. Strabo says that the concealed inscription read: “SOSTRATUS, THE FRIEND OF KINGS, MADE ME;” but Lucien gives it differently, thus: “SOSTRATUS OF CNIDUS, THE SON OF DEXIPHANES [that he might not be mistaken for any other Sostratus, doubtless], TO THE GODS THE SAVIORS FOR THE SAFETY OF MARINERS.”

Pliny does not share the opinion that the inscription was a concealed one, but speaks of the incident as a special instance of the magnanimity of Ptolemy, that he should not only have allowed the name of the architect to be inscribed upon the building, but that he should have also left its nature and language to the discretion of Sostratus. The words “Gods the Saviors,” he believes, referred to the reigning king and queen, with their successors, who were ambitious of the title “Soteros” or Savior.

It would be unfair, perhaps, to the great Grecian architects of the time of Alexander if Andronicus Cyrrhestes were to be classed among them, and Cyrrhestes also, having been a scientific character with a leaning toward astronomy, might with some justice feel aggrieved were he to know that he was to be considered in a category of professional men to which his calling was in no degree related. Still the little building which he designed and erected in Athens is such an interesting one, and has always held so prominent a place among the architectural treasures of the Attic city, that it might be regarded as an intentional oversight to leave him out in a book of this kind. Some authorities place this building as belonging to the time of Alexander the Great, others believe that it was erected at a later period, and one writer gives Andronicus an existence as late as 100 B.C.

This building, which Delambre speaks of as “the most curious existing monument of the practical gnomonics of antiquity,” has sometimes been called the “Tower of Æolus.” Let us see what Vitruvius has to say regarding the winds and the building: “Some have chosen to reckon only four winds: the East, blowing from the equinoctial sunrise; the South, from the noonday sun; the West, from the equinoctial sun-setting; and the North, from the Polar Stars. But those who are more exact have reckoned eight winds, particularly Andronicus Cyrrhestes, who on this system erected an octagon marble tower at Athens, and on every side of the octagon he has wrought a figure in relievo, representing the wind which blew against that side; the top of this tower he finished with a conical marble, on which he placed a brazen Triton, holding a wand in his hand; this Triton is so contrived that he turns with the wind, and always stops when he directly faces it, pointing his wand over the figure of the wind at that time blowing.”

It is in connection with his allusion to the tower of Cyrrhestes, and his description of how to construct a sun-dial, that Vitruvius gives some valuable hints as to the way the ancients laid out a city so that its streets were protected from the prevailing winds. He says: “Let a marble slab be fixed level in the centre of the space enclosed by the walls, or let the ground be smoothed or levelled, so that the slab may not be necessary. In the centre of this plane, for the purpose of marking the shadow correctly, a brazen gnomon must be erected. The shadow cast by the gnomon is to be marked about the fifth ante-meridional hour, and the extreme point of the shadow accurately determined. From the central point of the space whereon the gnomon stands, as a centre, with a distance equal to the length of the shadow just observed, describe a circle. After the sun has passed the meridian watch the shadow which the gnomon continues to cast till the moment when its extremity again touches the circle which has been described. From the two points thus obtained in the circumference of the circle describe two arcs intersecting each other, and through their intersection and the centre of the circle first described draw a line to its extremity: this line will indicate the north and south points. One-sixteenth part of the circumference of the whole circle is to be set out to the right and left of the north and south points, and drawing lines from the points thus obtained to the centre of the circle, we have one-eighth part of the circumference for the region of the north, and another eighth part for the region of the south. Divide the remainders of the circumference on each side into three equal parts, and the divisions or regions of the eight winds will be obtained; then let the directions of the streets and lanes be determined by the tendency of the lines which separate the different regions of the winds. Thus will their force be broken and turned away from the houses and public ways; for if the directions of the streets be parallel to those of the winds, the latter will rush through them with greater violence, since from occupying the whole space of the surrounding country they will be forced up through a narrow pass. Streets or public ways ought therefore to be so set out that when the winds blow hard their violence may be broken against the angles of the different divisions of the city, and thus dissipated.”

This tower still stands a fairly well-preserved ruin, and retains many of its original architectural features and decorations. There are two entrances through distyle porticos, the capitals of the columns presenting an original treatment of the Corinthian order. One of these entrances is on the northeast side and the other on the southwest. On the south side is a circular apsidical projection. This was probably originally used for a reservoir to hold the water brought from the spring Clepsydra, on the northwest of the Acropolis, which was employed as the power to run a clepsydra, or water-clock, taking its name, as may be inferred, from the spring. The

remains of this clock are still visible. The exterior of the building was also arranged as a sun-clock, having lines engraved upon the different sides, with gnomons above them, forming a series of sun-dials which indicated the time by shadows. Thus were the people of Athens kept publicly posted as to the time of day—by the sun when it shone, or by the water-clock when it was obscured by clouds.

The character of the architecture, the proportions of the building, as well as its secular uses, were all quite out of harmony with Grecian art and methods, and are essentially Roman. As a similar structure existed at one time in Rome, supposed to have been built by the same scientist, the thought is naturally suggested that Cyrrhestes may have been a Roman.

In closing this reference to the prominent architects of the disintegrating period of Grecian history, it would seem that it only remains to recall Philo, or Philon, as some of the writers have preferred to call him, once more, who flourished about 318 B.C. As there were several artists of his name who became conspicuous at about the same time, our Philo will be distinguished from the others in being a native Athenian.

The reader will probably remember that he has been already mentioned as the architect employed by Demetrius Phalerus, to build a portico of twelve Doric columns to the great temple of Ceres and Proserpine at Eleusis, originally erected by Ictinus; but his most ambitious work was probably the armory, so called, which he designed for Lycurgus in the Piræus, and which it is said was large enough to contain the arms for one thousand ships. He was also engaged in enlarging the port of Piræus, and was the architect of the white marble theatre at Athens, which was finished by Ariobarzanes, and many years afterward rebuilt by Hadrian. Vitruvius says that he also designed a number of Greek temples.

Philo must have been a man of considerable versatility, for it is related that in giving an account of his work at Piræus “he expressed himself with such precision, purity and eloquence that the Athenian people—excellent judges of those matters—pronounced him equally a fluent orator and an admirable architect.” He wrote also several works on the architecture of temples and one on the naval basin which he constructed in the Athenian port.

THE END.

The Truth About the Tobacco Habit

T. Swann Harding

HALDEMAN-JULIUS PUBLICATIONS GIRARD, KANSAS

Copyright, 1929, Haldeman-Julius Company

PRINTED IN THE UNITED STATES OF AMERICA

THE TRUTH ABOUT THE TOBACCO HABIT

A young friend of mine of the trouser-wearing male sex recently developed a pain in his stomach. He decided to wait it out. But it was an indecent as well as an insidious sort of pain and finally persisted so long that he was driven to consult a physician for moral support. The physician said, “Do you smoke?” My friend said “Yes.” The physician said, “That’s it, of course. Quit smoking. Three dollars, please.” My friend went away, quit smoking, and the pain persisted. He returned to the doctor. He was now given a little silver nitrate. He went away, but he came back again. By that time the physician was really angry. He said, “You’ve smoked yourself into a nice stomach ulcer, you have. I’ll have to operate. I hate to but I have to.” Just then buckwheat cakes and sausage made my friend violently ill one day and he deleted them from his diet. The pain left and has not yet played a return engagement. He smokes more than ever now, but he throws away longer butts.

Another friend of mine classifying in the male sex which so far tends to avoid wearing trousers--much--went to a physician. She complained of a rash which she said afflicted her all winter. Fortunately for the physician she smoked energetically. He therefore told her to quit and called the next patient. Since she knew that she smoked in summer as well as in winter she did not quit but, by chance, consulted a scientific nutrition investigator. There was no reason for this; she did it irrationally and by pure inadvertance. But he asked, “Do you eat anything in winter that you do not eat in summer?” And she at first said, “No,” because that is the most natural answer to make under the circumstances. Then later, after a half an hour’s cross-examination, she said, “Yes, oatmeal.” He said, “Try cutting that out for a while.” So she conquered this craving, but continued to smoke, and the rash departed for parts unknown. She had an idiosyncrasy for oatmeal proteins just as some people have for strawberry or egg proteins, and her rash was thus caused.

In a moment of more violent perversity I went not long ago to a lecture advocating ruthless war on tobacco. In spite of the success women have just had in smoking anti-cigarette reformers into comas, the speaker, Daniel H. Kress, M. D., was President of the Anti-Cigarette Alliance. Since he was a regular doctor in active practice I had a right to expect the presentation of a scientific case against tobacco.

This gentleman, who is personally one of the most delightful old souls in the world, actually completed his lecture without ever once citing a scientific authority, without once grounding upon irrefutable scientific fact and without departing widely from the most trivial and childish sort of argument from analogy. Thus he stated that a famous war hero did not smoke. Wilson did not smoke. Hughes does not smoke. The inmates of reform schools all smoke. Smokers are physically and mentally unsafe!

This may all be true for all I can prove to the contrary, but what of it? Many war heroes smoke. Grant certainly did. Small, defective and generally backward children normally spring from parents who underfeed them, who are themselves defective in heredity and who neglect to instruct their children in any essential matters. Can you prove that smoking alone either stunted them or put them in the reform school? You cannot. Criminals are predominantly religious according to their professions of faith. Did Christianity make them criminals? If smokers are mentally unsafe may I fervently declaim--God help research!

You hear it said that the children of smoking mothers are inferior. Are they? How can it be proven? As a matter of fact no scientific experiment could possibly be carried on to prove this, for statistics, being riddled by all sorts of idiosyncrasies and unknowns, are grossly unscientific. To prove it you might have the same mother have two children at separate times by the same father, smoking while she bore one and abstaining for the control child. But that would prove nothing. Each child is a unique individual arising from a unique chromosome mixture. The mother and father would of necessity be older in the one case than in the other. Nourishment and other environmental conditions would inevitably vary. The experiment is impossible. Yet until such an experiment becomes possible we are merely voicing opinions when we say that smoking causes inferior children. The actual cause may be any of a thousand other and extraneous factors.

When you consider how very often tobacco smoking is mentioned therapeutically and how universally it seems to be assumed that it is deleterious to health it is rather disconcerting to discover so little reliable scientific work to confirm this prevalent viewpoint. In fact practically no comprehensive, systematic work has been done by scientific research to prove that smoking is exceedingly harmful to the human system. Like so many other human preconceptions this assumption rests largely upon faith. To the acutely prejudiced non-smokers smoking seems so utterly perverse that it surely must be physically injurious.

A rational esthetic case could be made out against certain women smoking. True, the modern woman so sedulously apes the other sex that to deprive her of her cigarette is simply to deprive her gracelessly of her masculinity. We should never do that. But the spectacle of a really pretty, effeminate woman smoking is nevertheless an esthetic affront. Nothing the average man can do could make him look very much worse than he does naturally so even this slight objection does not apply bisexually.

But we have wandered, and I am of course at fault, having set out laudably to lead our thought procession. In my search of the scientific literature the nearest thing to an authority I came across was perhaps Sir Humphrey Rolleston, Baronet, K. C. B.; F. R. C. P. and M. D. of Cambridge, England, physician to King George V in his late 1928 illness. He discusses “The Medical Aspects of Tobacco” in such staid British medical journals as _The Lancet_ and _The Practitioner_. He reviews every possible lesion that might spring from tobacco smoking, and they are many--quite as many indeed as may spring from over eating artichokes or drinking three gallons of well-water daily. He sets himself flatly against animal experimentation in this matter because this cannot possibly take idiosyncrasies into account, and reminds us that humans are both highly individualized and exceedingly complex.

Rolleston then remarks that cigarettes are less invidious than pipes or cigars because cigarette smoke is more air diluted. He finds a wide diversity of opinion as to the harmfulness of tobacco; he doubts that it ever affects the nervous system greatly and believes that coffee and tea usually produce the heart symptoms attributed to smoking and that a latent venereal disease accounts for much smoker’s cancer. He doubts also that dilation of the esophagus, dilation of the stomach, acid stomach and nervous dyspepsia are often due to tobacco while he commends the mildly laxative properties of a pipe after breakfast.

Finally our baronet says, and the medical journal sustains him editorially, that in view of the universality of the habit of tobacco smoking the rarity of the organic lesions that can be traced out as undoubtedly due to that habit, beyond all question, is little less than surprising. This, I should say, is the woodpile Ethiopian. It is one thing for a physician to lean back and say cut down on tobacco, coffee, fried stuff and pastry. It is quite another for him to prove scientifically that these indulgences have undeniably caused the patient’s present low physical estate.

D. T. Barry, F. R. C. S. and M. D. of the Physiological Department, University College, Cork, is not very far off when he writes: “The physiological effects of tobacco, as our present knowledge reveals them, are not sufficiently deleterious to counter-balance the benign influence of the drug in other respects. It may be abused, of course, but so may food, and this latter form of abuse is, in my opinion, responsible for greater evils than those resulting from the abuse of tobacco.”

In this connection another authority, Armstrong-Jones, remarks that tobacco smoking in moderation is not injurious to adults but is a valuable sedative. It contributes to calm thought and efficient mental functioning. Worst of all he casually remarks that cigarette smoking, preferably without a holder, is the least injurious form of tobacco indulgence. Even allowing for the fact that the gentleman has seen some of the less comely holders I have witnessed in my time, his statements give pause.

Of course Earp’s well-known studies at Antioch College, Ohio, did indicate that non-smokers showed an intellectual superiority over smokers, but whether these things were cause and effect or mere harmless concomitants who knows? Many very eminent intellectual giants smoked excessively. Perhaps they would have achieved absolute omnipotence or omniscience had they been non-smokers. Again, who knows?

It is significant that Earp's non-smokers showed no physical superiority over his smokers; that is, it is interesting when you remember that the American university is an institution of athletic training wherein some intellectual education is offered to the feeble-bodied as a consolation prize. Intelligence tests are not affected by smoking, the non-smokers ranking just as high after smoking as before they had ever touched the vile weed. Finally, the correlation between the length of a student's indulgence in tobacco and his scholarship is so negligible as to indicate that there can be no chronic cumulative poisoning from tobacco.

Laymen do not realize how difficult it is to trace a diseased condition to a specific cause even when bacteria abound, as is not the case in smoking. For instance certain bacteria so closely resemble each other that even experts are hard put to tell them apart. Diphtheria germs possess such a dead ringer. Real diphtheria cultures were once sent out to clinical laboratories along with other cultures containing no diphtheria germs, but germs so closely resembling them that the laboratories involved returned all sorts of results. Some reported that the actual diphtheria cultures contained no diptheria germs at all; others that some of the germs simulating diphtheria in appearance were positively the real thing. So a tooth or a tonsil may contain a germ so similar to those found at the seat of secondary infection that they are indistinguishable, yet the germ may be harmless in one case and virulent in the other.

Certainly it is unlikely that we carry virulent germs about in teeth and tonsils for long years. For one thing they get acclimated to us and can change their murderous habits. For another we get used to them. This organism of ours is an hospitable sort of thing. The body tends to adjust in neighborly fashion to germs upon long acquaintance, or familiarity breeds contempt, just as it adjusts to morphine, to opium, to over-eating, to the corrosive harness oils now sold as bootleg whiskey and to tobacco, of course. Perhaps long acquaintance ripens into real friendship and mutual aid.

Nicotine is the active agent in tobacco. Mendenhall tells us that tobacco sometimes stimulates and sometimes depresses the bodily sensory mechanism, depending largely upon the state of fatigue prevalent at the moment. When stimulation occurs the effect is precisely that of a certain portion of high potential rest, for in this case, says our authority, tobacco has rested us artificially.

Certain work seems to prove quite clearly that tobacco slows down the gastric motility as well as pepsin and rennin secretion. At least it produced such results on certain individuals, although the majority of mankind may be immune for all we know. This would slow down digestion, but it takes considerable smoking to accomplish such a result even with the susceptible, and one cigarette after a meal, even a cigar, would scarcely be sufficient. It has also been stated in scientific journals that tobacco _may_ play an etiologic role in gastric neurosis, in gastritis, in ulcer and cancer of the stomach and, likewise, in mouth or throat carcinoma.

But, putting your mind rigidly to the task, can you readily think of anything from hot soup to worry that has not at some time by some person been accused of causing these conditions? Why is this? Holding a clay pipe in the mouth may cause mouth cancer; holding an ordinary pipe might; continuously holding a roughened stick there might also, with tobacco never involved. How do these anti-tobacco ideas arise?

Why are we told that so many things cause ulcer, cancer, kidney trouble, heart lesions or high blood pressure? Why are there so many theories of evolution or of creation, or of salvation for that matter? Why are there so many and such diverse theories of economic and political betterment? Why are there such varied schools of treatment often imposing diametrically opposed procedures to combat the very same maladies? Why do men differ so widely in their hypotheses about government, religion, tobacco, women? Simply because nobody as yet knows anything positively definite about these matters, and just so long as this condition of inspired ignorance persists, so long will infinitely varied opinions be inevitable.

In chemistry, in physics and in bacteriology, for instance, we do possess certain definite knowledge and we can rightfully cite certain facts. In sociology, in politics and in economics, we possess certain dogmas or beliefs and we can pardonably express certain theories or opinions--so long as we candidly admit their opinionative status. But when we get beyond a certain definite point in any science, even in physics and chemistry, we begin to hypothecate just like an economic determinist or an anti-vivisectionist or a religious fundamentalist, people who are habitually beyond this point of separating fact from belief anyway. We begin to express our opinions vociferously, to dress them up in moral overcoats, and to justify them just because we do lack certain scientific knowledge.

Thus we can go to the scientific work and find an investigator saying that very large quantities of tobacco smoke will paralyze the gastric contractile power. All right. But this very same investigator also sagely adds that small amounts of the smoke will actually stimulate this very gastric contractility and urge along digestion. Or we can go to the _Journal of the American Medical Association_, the highest current medical authority in the United States. We find a query by some doctor on cigarette smoking and

we read the reply. Authority completely absolves cigarette papers from blame for poison. It adds that any cigarette smoker is safer from harm than a tobacco smoker of any other sort. For one thing he actually smokes less tobacco. If he nervously smokes many cigarettes he throws away longer and longer unused portions and thus keeps his consumption at about the same figure.

The Laryngoscope should be an authority on throat conditions as it is the publication of throat specialists. We find in here a statement to the effect that from a medical or laryngeal point of view there is no reason why anybody should give up tobacco or alcohol if it does them no very apparent harm. This is because the use of both in moderation by millions proves the harmlessness of the habit which is, in fact, often actually beneficial.

You can go further than that. If you want to be really mean you can find an authority to state that visual acuity is increased by smoking. When non-smokers smoked for they first time they saw better than they did before smoking. The sight of habitual smokers was unaffected by an additional smoke. They had already smoked themselves into the best possible eye-sight. This may be unreliable testimony. Far be it from me to judge it. The point is that it is quite as reliable as any of the testimony advanced against the tobacco habit.

In short we are here in a region where exact scientific investigation has not yet established reliable criteria of judgment. We cannot cite irrefutable facts. We can only express opinions and opinions are usually grounded in prejudice. Physicians tend normally to prohibit, but they rarely prohibit judiciously because, under our present chaotic medical system, they cannot afford to make a sound, thorough-going clinical examination of every patient and must regard medicine as an art--_i. e._, fall back upon empiricism.

As for prejudice, it amounts to little. Cromwell and his Puritans smoked excessively. About 1840 women smoked outrageous stogies and cumbersome pipes so shamelessly that men were alarmed and vigorous caricatures satirized them in the periodicals of the day. Early in the Victorian era smoking was all but a lost art. Today it is again in ascendency, yet human depravity has remained at about one level throughout.

In an editorial upon the subject during 1925 _The Journal of the American Medical Association_ especially emphasized the fact that variations in human susceptibility and tolerance were factors as yet little understood. Extreme caution in generalization was wisely advised on such subjects as the harm inherent in tobacco smoking, and the reader was admonished that over-indulgence in turnips or parsnips, or even in water, would turn out a great deal worse than he might anticipate on immature consideration.

This factor of human individualization is rightly coming to the front in medical literature today. Advances in biological chemistry constantly attest the fact that each human individual is unique chemically. What Smith can do with impunity Jones can only do with a prospect of sudden death. This is not a superficial matter, but one deep seated in the cellular structure of the human body, a thing going back through ages of inheritance via the complex and ill-understood chromosome. More and more it is being realized that routine diets, prescriptions and prohibitions will not do in all cases--in fact are actually unsafe and dangerous in many.

For all we definitely know today with positive assurance we cannot deny the proposition that tobacco smoking is probably beneficial to many people. Not long ago everybody was urged to go in for bran because we all sadly needed roughage. Bran would cure constipation and a thousand routine diets spattered the press. It was all very well, except that constipation persisted. Today it is realized that nervous and psychic factors have much more to do with constipation than diet and the parade has set in that direction now. In fact some authorities declare that these rough diets have actually had fatal consequences in certain instances where a smooth diet was required.

But medical science really does not know sufficient about the positive, absolutely undeniable effects of tobacco smoking upon human beings to parade in any direction as yet without painful danger of finding itself hopelessly bogged in error at some date in the near future.

DEBUNKING “DENICOTINIZED” TOBACCO

Some years ago it was quite evident that the cigarette was doomed. Groups of well desiccated females, assisted by large droves of impotent he-virgins, met together, assailed the “filthy weed,” and determined to abolish it by vituperation if not by legislation. Tobacco manufacturers began to feel vague worries, some States passed anti-cigarette laws and righteousness seemed about to triumph. Then came the war!

War is a great release. We all live pretty prosaic lives. Social conventions are harsh and unless we live in Philadelphia or Chicago it is not considered courteous, much less expedient, to go out and rob, kill and commit arson. War delights in that it releases these

crude desires which seem to be suppressed and lying potentially in wait in the most sedate of us. Men were released to rob, murder and commit arson and they did it with a vim and vigor which belies the idea that we are becoming a decadent and anemic race.

At the same time war had its disadvantages. A chap needed stimulation. He needed whiskey; he needed women; he needed cigarettes. He got them all and the dear, good Christian souls applied themselves so whole-heartedly to the good work of providing needful stimulation that natural smiles began to sprout on technical virgins, liquor ceased to draw the sex line and cigarettes were actually dispensed by the hands of Christian ladies and gentlemen. The tobacco industry was saved.

After the war women decided to continue doing what they had done during the war. They decided to retain “This Freedom.” Men decided they should not retain it. The Christians decided they should not retain it. It was against ethics, morals and law. The women retained their freedom and added to it. Among other things they smoked cigarettes so indefatigably that a consumption which had commenced to decline hopped to a point of unprecedented size.

Women are like that. Men are more civilized, have more modern bodies, are younger in an evolutionary sense and respect this nonsense called law. Women are much older physiologically--phylogenetically for that matter, if you really like long words. They adopt primitive means to accomplish their ends and primitive means are always effective. When they wanted to smoke they smoked and that was that.

At the same time, however, it is vaguely interesting to many people to know whether smoking is injurious. All sorts of ills have been laid to its door. But there is this to be said in its favor. In very many people smoking is undoubtedly the percussion cap which sets in motion a train of conditioned reflexes and enables them to work efficiently.

Watson has worked on these conditioned reflexes. Let the young baby have a rat. It is not afraid and will play with it happily. But some day produce a blinding flash of light or a loud noise just as you give it the rat and you have imbedded a conditioned reflex which may last its life. It will always fear rats. Watson holds that education should address itself to the job of making our conditioned reflexes of such nature that they are helpful rather than a hindrance.

Thus a certain man cannot think unless he plays with the keys in his pocket. That is the original stimulus which sets his benign conditioned reflexes in motion. Another smokes in order to think deeply. A third smokes and finds that it is laxative. Perhaps these men cannot either think or avoid constipation unless they smoke, and the probable reason is that the act of smoking is an original stimulus which automatically sets in motion a long series of conditioned reflexes of a benign character.

Yet there are people who do not want to run any risks. They want to avoid nicotine. Perhaps it is as well that they should. They therefore buy cigarettes or cigars or tobacco which have been “denicotinized.” To what extent do they succeed in avoiding the poison then? The Connecticut Agricultural Experiment Station Bulletin 295, a prosaic scientific-looking thing, pretty well explodes the bunk of these tobaccos and it calls a spade a spade. More power to the research agencies of the U. S. A. which dare be so outspoken. A brief analysis of the results shown seems in order.

Tobaccos were analyzed for nicotine and the percentage given is in all cases on a dry basis. First tested were several common brands of cigarettes. They ran as follows in nicotine. Take your pick hereafter when you buy--

Cigarette. Percent Nicotine. Egyptian Deities 1.28 Pall Mall 1.38 Philip Morris 1.40 Lucky Strike 1.88 Camel 2.21 Old Gold 2.17 Capstan Navy Cut 2.30 Chesterfield 2.53 Piedmont 2.89

Since not even physicians have had any idea how much nicotine common brands of cigarettes carried this alone is important. Now how did the “denicotinized” cigarettes line up? They ran as follows:

“Denicotinized” Percent Cigarette. Nicotine Sano 2.32 Cestrada Virginia 2.10 Dormy Turkish 1.19 Sackett 1.02

Next I shall list the cigars and the smoking tobacco analyzed--

Normal

Reyes de Espana 1.16 Manila 1.31 Knickerbocker 1.90

“Denicotinized”

Sano 1.07 O-Nic-O .72 Sackett .67

The smoking tobaccos tested ran--

Normal

Blue Boar Pipe 1.45 Weldon Slice 1.84 Hudson Bay Imperial 1.95 Gilbert's Mixture 2.09

"Denicotinized"

Dormy Smoking 2.26 Sackett .98 O-Nic-O .97

In short, the average for all brands tested stood 1.77 percent nicotine straight and 1.28 percent still in the "denicotinized" products. Seventy-two percent of the nicotine remains behind. The process is, like the process of removing caffeine from coffees, very largely bunk but it is bunk that makes the American people spend their money, as Barnum very well knew. A person can with considerable ease select an ordinary tobacco which is so near the nicotine content of the "denicotinized" varieties that he scarcely seems justified in paying the higher prices for the treated product.

Was ever a nation so neurotic over its health as ours? European observers are constantly amazed at the imbecile delight we show in all sorts of products especially treated to make them less toxic, more digestible, less harmful and more beneficial. Just tell an American that you have vacuum treated your coffee and have thereby removed some obscure organic compounds which normally tie his stomach in knots and he will faithfully believe you and buy it. Tell him you have taken the nicotine out of his cigarette and though 72 percent of it is still there he will buy. Tell him Grapenuts make his teeth sound and he will buy. Tell him that he can improve his health by standing on his head on a cake of ice in a blast furnace while somebody shoots a stream of liquid platinum in his left ear and you will find some fool to do it in America. Why are we such damned fools? I am not going to tell you. I don't know. But we are.

IS COFFEE DRINKING HARMFUL?

It is recorded in the annals of history that a certain doctor once told a certain patient to drink no coffee. Were you, perchance, the patient? I know I was. But why did the doctor say that? Because if we stopped there would be more coffee left for him?

It is also recorded that there once lived a certain Arab whose name comes down to us as Chadely. Chadely is reputed to have been the initial coffee drinker of the world and he drank an extract of the berry to combat a continual drowsiness which prevented him from attending punctually his religious devotions! In this others of the Mohammedan faithful rapidly followed him, and the habit might well be cultivated by certain church-going Christians with sedative pastors.

Now I am one of those most unfortunate persons over whom alcohol has no appreciable authority. I confess this with shame and deep humiliation. Right in this Prohibition Era when various nondescript alcoholic beverages are held in higher esteem than ever before in our history (for does not the lowliest shellac now become a sacred and inviolate symbol of a personal liberty we would not recognize in this collectivist country if we saw it?) I can drink one, two or even three glasses of high voltage and yet remain placid, neutral, passionless, taciturn and erect in posture. So far as I am concerned even the dynamic and remorseless cocktail of these days is just so much ill-tasting liquid. Isn't this tragic?

But I would not prohibit the sale, ingurgitation or even the flagrant abuse of these curiously synthesized beverages, or even of good alcohol drinks. Not for one single prohibitive instant. For I want my coffee and some day some bluenose wowser might seek to deprive me of the cup that really cheers me. For I can arise in the morning hopeless, misanthropic, pessimistic, with a strong suicidal impulse, a feeling of uselessness and a Calvinistic conviction of sin--yet one cup of good coffee completely reverses my emotions and stirs me to optimism, confidence, cheer and incipient exaltation. I can be induced to consider new fur coats and parlor rugs.

Or again, in the evening, I may have sunk into a mental stupor, becoming in fact so definitely subhuman that I can only listen to a radio or read a newspaper--but coffee at once changes the entire universe and suffuses me with self-satisfaction, energy, will power and complacency--jostles my brain cells rudely against each other and clicks out of them what little useful information there is in them. Indeed I strongly sympathize with any dull soul who momentarily sweeps aside the stagnant miasmas of toil, monotony and misery with a swig of ethyl alcohol--in varied disguise. Insensitive to alcohol I do exactly the same thing with caffeine.

It is a most curious matter upon which to meditate. The entire universe is not something static and permanently postulated by definition. It is not even what I made it a moment ago. It is what coffee makes me and makes me make it at this moment. Leaving

my entire environment, debts and all, and my complete mental and somatic equipment _in statu quo_ one dash of caffeine completely reorganizes the universe for me and as completely modifies my reaction thereto. The final test in any scientific experiment takes place when one variable factor accomplishes such results while all other factors remain completely unaltered. I know my coffee.

But of course this is a world wherein doctors sound solemn tocsins to pleasure. You go to them and they almost invariably admonish you to quit smoking tobacco and drinking coffee, to have your teeth pulled and your tonsils uprooted. Some years ago I myself suffered from chronic indigestion. I was on a meticulous diet which lacked meat and coffee and I was about ready to accuse coffee alone of all my indispositions. But I met a hardy old codger of eighty who drank eight cups of strong coffee daily and had but recently reduced his consumption from a normal dozen and his vigor, which he attributed to seventy years of strong coffee, greatly heartened me. I knew what the doctor would say. I didn't smoke. Teeth and coffee alone were left. So I went soberly to the expert in exodontia.

He at first demurred and insisted that I had no teeth meriting destruction. But I was desperate. I insisted. So he X-rayed around, finally selected an inoffensive and courteous molar and drew it. The shock or something proved beneficial. At least I had no more indigestion and even learned how to drink two cups of strong coffee and go to sleep on the draft. This is the final step in expert coffee drinking. When you can perform that feat and outwit your imagination you have come into the inner circle of The Sacred Coffee Drinkers' Conclave.

But I remained curious. I wondered why doctors said drink no coffee. I determined to find out something about this. Botany didn't get me very far. It simply declared "Coffee is the product of a rubiaceous plant indigenous to Abyssinia of the _genus_ coffea; there are about twenty-five known species, of which coffea Arabica is the most important commercially."

History was slightly more productive. It appeared coffee drinking was of respectable age and that the substance derived its name from K'hawah, or Kaffa, an Abyssinian Province, and that there it was employed as a stimulant for centuries before its introduction into Arabia. The Arab physician Khayes, who lived 850-922 A. D., wrote on coffee and knowledge of the plant arrived in Europe by the late sixteenth century. It is most interesting to remember that these Arabian Mohammedans used coffee as an anti-soporific during prolonged religious ceremonies. Yet the beverage at first underwent violent protest because strictly orthodox and conservative priests held it to be intoxicating and hence under the ban of the Koran.

At Constantinople certain dervishes also held that after roasting coffee had become a kind of coal which the Prophet had denounced as inedible. Thereupon the coffee houses were closed. But a lenient mufti later proved to the satisfaction of the faithful that roasted coffee was not coal and they were reopened.

The earliest European coffee houses were established, in fact, in Constantinople and in Venice. The first one appeared in England in 1650; out of it grew the Oxford Coffee Club in 1655 and from that sprang the Royal Society itself. But alas, convivial gatherings at coffee houses became of ill repute; wives complained they could not expect their husbands back from errands because they would loiter in coffee houses and kings declared that their subjects met at coffee houses, became garrulous and bespoke political rebellion. The current Volstead, Charles II, therefore, sought to suppress coffee drinking, but evidently Anglo-Saxons valued their liberties more then than now for the King had little success. Frederick the Great, fearing coffee drinking for the more thrifty reason that it caused too much money to leave his domain, boldly attributed sterility to indulgence in the berry and sought to restrict the use of coffee by a license system.

The medical profession came forward to denounce coffee for all sorts of sins. The English Dr. Pecoke accused it of causing leprosy. Dr. Duncan of Montpellier in 1706 wrote in opposition to all hot beverages while James the I actually composed a royal "Broadside Against Coffee." The kingly book contained this gem--

Confusion huddles all into one scene, Like Noah's arks, the clean and the unclean, For now, alas! the drink has credit got, And he's no gentleman who drinks it not.

Millingen in his "Curiosities of Medical Experiences," 1837, said that coffee in excess produced "feverish heat and a predisposition to apoplexy." But he did commend coffee and tea as beverages affording stimulus without producing intoxication. Francis Bacon declared that "coffee comforteth the heart and helpeth digestion" while Bach, to offset this, wrote his Cantata No. 211 of the "Secular Cantatas" to protest its use.

In 1792 Dr. Benjamin Moseley said doubt existed as to whether coffee was a tonic or a sedative, but believed that it had intrinsic food value. Every now and then individuals arise to denounce or to praise an article of diet or a diet system and to declare that all men should hear and follow because this idea was of benefit to them. Such statements can have no standing in science, even when made by a doctor and based upon his actual experiences with a few patients. The only possible way to find out whether coffee, say, is beneficial, or the reverse is to investigate the literature and try to poll the authorities each one of whom has examined large numbers of individual cases to see if any general statements can be hazarded. Even then we cannot make final conclusions but we can assay general trends.

Is coffee harmful then? What do physiologists, pharmacologists and medical men say? Coffee demonstrably enlivens the intellect, removes the sensation of fatigue and makes the subject feel more comfortable. These are gifts not to be sniffed out of court. But is coffee safe and harmless enough that we may dare indulge ourselves in this pleasant reaction in a world where the pleasant is so readily assumed to be _per se_ the invidious--and so often is actually so? The question is in dispute like most questions considered settled by many people. There is no more reason to conclude one way than the other in so far as average adults are concerned. All who say dogmatically “No coffee--it is very harmful” are as wrong as all who state the opposite of this.

In his “Personal and Community Health” C. E. Turner says coffee is not harmful to most adults in reasonable quantities. G. N. Stewart’s “Physiology” remarks that tea and coffee are safe stimulants because they have no bad after effects. Stewart also cautions against their abuse, but it may as well be stated at once that the question of abuse introduces an altogether new factor. Water and salt are absolutely necessary to life but the abuse of either is injurious. We can produce true water intoxications and salt eaten to excess can do us much harm. All articles of diet from parsnips and lamb chops to caffeine and alcohol can harm if abused and we should assume when speaking of them a sane, rational use and regard abuse as a harmful condition of a different order altogether.

As C. E. A. Winslow well says in his “Healthy Living”--“The fact that tea and coffee sometimes become tyrants does not mean that such drinks are necessarily bad.”

In one thing medical authorities do agree, however, coffee and tea are not beverages for children. Moralists to the contrary notwithstanding, this is again beside the point when we are considering the reasonable use of coffee by adults. Adults and children are essentially different animals using their food intake differently--the one for upkeep and repair the other for new construction as well as upkeep and repair. They differ basically in metabolism. They have different metabolic rates and different expenditures of energy. The child is turning food into flesh and bone and blood at a much greater rate than a fully-grown adult organism is ever required to do. Diets which would amply sustain an adult may easily be detrimental to or deficient for young and growing children. We shall, then, restrict ourselves herein to the rational use of coffee by average adults. What can coffee, or its active principle caffeine, do to harm adults?

Caffeine definitely increases the force of the heart beat. Yet Wood, “Notice of Judgment Under the Food and Drugs Act No. 1455 1912,” says such an effect may be desirable since a slower rate and increased force induce cardiac efficiency. Heavy coffee drinking may produce a frequent, hard pulse and palpitations, but this again goes over into the territory of abuse.

Coffee tends both to dilate the vascular system and to constrict it, the net result being a mass movement of the blood without increased blood pressure. Coffee has repeatedly been suspected of damage to the heart and blood vessels but such suspicions are common in therapy and evidence is entirely lacking to prove this point scientifically. Suspicion is here probably no more legitimate than in many lay superstitions. While patients with definite heart trouble should avoid all stimulants the normal use of coffee by an adult cannot be said to have an insidious effect upon the heart and blood vessels.

While coffee is a diuretic it cannot be convicted of renal injury as yet. Indeed it is quite probable that the kidneys become accustomed to caffeine while A. R. Cushny (J. Pharmacol. & Experimental Therapy 4 363) declares that caffeine does not injure the kidneys even when given in large dosage over long periods.

But how about digestion? Years ago Fraser (J. of Anatomy & Physiology 184 13 1883) said that coffee and tea hindered the digestion of protein foodstuffs with the exception of ham and eggs! This very fortunate immunity renders the typical American dish a safe breakfast in any case. In general, however, observations _in vivo_ indicate that the amounts of the beverage usually taken have no evil effects upon digestion. Indeed some investigators have found a pronounced increase in gastric secretion following tea and coffee.

Hutchinson in his “Food and Dietetics” says that the digestive disturbance caused by such infused beverages is negligible in health. Others have held that the aromatic constituents of coffee, or the “empyreumatic oil,” upset digestion. There may be some reason for this; at least certain individuals tolerate much better coffee from which these substances have been removed.

Caffeine is of course a stimulant to the central nervous system, particularly that part of it intimately associated with the gastric function. How far is its use as such a cerebral stimulant advisable? Like all stimulants this will result in greater fatigue on excessive usage. But as “The Medical Review of Reviews” once said, “When tea and coffee are made moderate in strength and partaken of in sober quantities they are gentle stimulants and their effect upon the nervous system is salutary.” A too constant reliance on coffee as a goad may of course result in nervous irritability.

Coffee speeds up the metabolism, increases the body heat and heat elimination, and perhaps urges us on to greater activity. But, as the English pharmacologist Dixon remarks in his “Manual of Pharmacology,” “Caffeine decidedly facilitates the performance of all forms of physical work.” Yet certain athletes are reported to have had their performances injured by coffee drinking, while Osborn holds that coffee interferes with the best muscular efforts. Take Hobson’s choice here, you have an authority either way and we do love some one to give our opinions an affidavit. It may be observed that coffee also increases the rate and depth of our respiration.

The following gracefully and euphoniously named aromatics have been found in roasted coffee--pyrol, quinol, methylamin, acetone, furfuryl alcohol, a derivative of saligenin, phenols, valeric acid, pyridin and trimethylamin. You are no doubt much surprised and edified to know that. Some of these compounds are toxic, but they occur in coffee in amounts far too small to be dangerous to health. Some have accused these formidably named derivatives of bad effects but the work existing shows caffeine to be the only coffee constituent of importance in its physiological effects. It is agreed that caffeine is very rapidly changed by the body into less active substances and disposed of, so there can be no cumulative effect even of that. In old age, as in youth, coffee, like other stimulants, should be used in moderation if at all.

As a whole then what can we conclude about the use of coffee by adults? Science has not found it harmful when taken in non-excessive amounts. Heart patients, neurotics, the young and the aged should avoid it. It has not been proven to cause pathological changes in the heart, blood vessels or kidneys. It is a valuable cerebral stimulant and antidote for mental fatigue, lacking as it does the bad effects of most stimulants. It also stimulates respiration and speeds up the metabolism, while its effects on digestion cannot be said to be definitely deleterious. Tea, because of its tannin content, is probably worse than coffee gastrically. Finally caffeine is rapidly oxidized and has no cumulative poisonous effect.

Most important of all we must remember that individuals differ. They are constructed of different proteins and have cellular and glandular processes differing from individual to individual. What one can do with impunity another will find bringing him nearer to the undertaker daily. In this as in all other matters dietetic common sense and sound judgment in appraising our own state of health and the reactions of our organism to various stimuli will always surpass slavish subservience to systems or morbid efforts to avoid all harm and achieve an impossible all good.

Then if we are to drink coffee let us consider momentarily how best to make it. One basic fact stands out--freshly ground coffee is best. Ground coffee loses its flavor on standing. It also loses its content of carbon dioxide. These two factors are definitely related but exactly how and why we do not know.

In considering coffee-making precise scientific methods are everything. Our mothers, more energetic than the decadent women of today, made their own bread. They often appraised various flours by such rude methods and declared this brand better than that. How much could they have known about it? Did they keep every factor constant except the flour when making their tests? You know they did not.

Go into the laboratory in the U. S. Bureau of Chemistry, where flour bought by the government is tested, and what do you see? You see an apparatus enabling the investigator to make bread from that flour holding every factor constant except the flour. All other materials used are precisely the same and all materials are carefully weighed. The dough is kneaded mechanically and timed exactly. Fermentation takes place in a cabinet at a constant temperature and for a definite time for all loaves. The same holds for the time and temperature of baking. The loaves are cooled just alike on wire meshes for the same time. They are weighed and their volumes measured. Then the investigator positively knows which flour makes the best loaf of bread and the government buys that flour for its hospitals and penitentiaries.

It is exactly the same with coffee. To test coffees they must be infused in very precise ways. How is it done? In the first place pulverized coffee must pass a 30 mesh sieve and be like fine cornmeal, medium ground coffee must pass a 10 mesh sieve and be like steel cut; coarsely ground coffee must pass an 8 mesh sieve and appear like the rude, home ground bean of our childhood.

Then boiling, boiling with egg, percolation and filtration must be tried on each by precise methods. A 40c. Mocha-Java coffee may be used with 12 grams of coffee and 240 cc. of water, except in the case of percolation which requires 480 cubic centimeters of water for 12 grams of coffee. In boiling with egg 10 grams of egg white were added. The infusion must be governed precisely.

Boiling takes place in a seamless white enamel pot, cold water being poured over the coffee, the whole brought to a boil and boiling continued for three minutes; the infusion then stood five minutes and was ready. It was strained through cheese cloth. Percolation was carried out in the usual manner with an ordinary percolator, the water being cold at the start and boiling being continued for five minutes. In filtration a wire strainer was put across the top of the pot covered with a piece of tennis flannel upon which the coffee lay. Boiling water was poured through once.

The brews were tested hot, for strength, color, and flavor by various people who did not know the methods of preparation. Six degrees of strength were observed with specific gravities of the brew by test as shown in the table--

Very weak 1.0045 Specific Gravity Weak 1.0055 Specific Gravity Moderately strong 1.0060 Specific Gravity Standard 1.0065 Specific Gravity A little too strong 1.0070 Specific Gravity Much too strong 1.0080 Specific Gravity

The specific gravity was taken on the cold brew and a standard, 1.0065 was selected for further tests. The following table indicating condition of coffee, method of brew, weight of coffee used and cost per cup is of considerable interest--

S. G. 1.0065 Cost Condition Method Weight Coffee per cup of infusion Grams cents

Pulverized Boiling 12.05 .63 Pulverized Percolated 12.78 .71 Pulverized Boiled with egg 12.85 1.05 Pulverized Filtered 12.31 .72 Medium Boiling 15.89 .83 Medium Percolated 22.94 1.29 Medium Boiled with egg 16.71 1.29 Medium Filtered 30.00 1.73 Coarse Boiling 19.79 1.03 Coarse Percolated 27.52 1.54 Coarse Boiled with egg 21.27 1.56

Hence it is apparent that pulverizing is the most efficient method of grinding. The best brew is made by filtration. Boiling with egg is second best while plain boiling and percolation are the poorest of all. In general, strength and color of the brew are quite independent of the blend and price but depend upon the grind. The flavor, however, varies markedly with the coffee brand and price. Java, Sumatra and Bogota give weaker infusions under the same conditions than do Mocha and Santos. The order of preference for flavor stood--Java, Sumatra, Santos, Bogota and Mocha. It was also observed that coffee which had stood long after grinding gave an infusion of a lower specific gravity and hence of impaired strength.

The effect of adding sugar and cream to coffee is not well understood. Some assert that the fat of cream and the fats of the coffee bean form indigestible compounds, but there is scarcely sufficient experimental evidence to justify this. The tannin compounds in coffee are apparently not precipitated, as has frequently been stated, by the addition of sugar and cream. Testing a centrifuged cream from a beverage coffee gave no appreciable evidence of tannin while the remaining coffee infusion gave the normal positive tests for tannin. It is certainly true, however, according to one authority that black coffee without any additional substances, with the possible exception of a portion of sugar, is the most beneficial form of the beverage.

Transmission of speech by telephones without diaphragm 360

THE TELEPHONE,

_&c._

HISTORY OF THE TELEPHONE.

Strictly speaking, the telephone is merely an instrument adapted for the transmission of sound to a distance, and this idea of transmitting sound is as old as the world itself. The Greeks made use of means which might effect it, and there is no doubt that these means were sometimes used for the pagan oracles. But such transmission of sound was within somewhat narrow limits, and certainly did not exceed those of a speaking-tube. Mr. Preece considers that the earliest document in which this transmission of sound to a distance is distinctly formulated, dates from 1667: he refers to a paper by one Robert Hooke, who writes to this effect: ‘It is not impossible to hear a whisper at a furlong’s distance, it having been already done; and perhaps the nature of the thing would not make it more impossible, though that furlong should be ten times multiply’d. And though some famous authors have affirm’d it impossible to hear through the thinnest plate of Muscovy glass; yet I know a way, by which ’tis easie enough to hear one speak through a wall a yard thick. It has not yet been thoroughly examin’d how far otacousticons may be improv’d, nor what other wayes there may be of quickning our hearing, or conveying sound through other bodies than the air; for that is not the only medium I can assure the reader, that I have, by the help of a distended wire, propagated the sound to a very considerable distance in an instant, or with as seemingly quick a motion as that of light, at least incomparably quicker than that which at the same time was propagated through the air; and this not only in a straight line or direct, but in one bended in many angles.’

This plan for the transmission of sound is the principle of the string telephones which have attracted attention for some years, and it remained in the stage of simple experiment until 1819, when Sir Charles Wheatstone applied it to his magic lyre. In this instrument, sounds were transmitted through a long strip of deal, with one end in connection with a sounding board: one step more led to the use of the membrane employed in string telephones. It would be difficult to say with whom this idea originated, since it is claimed, as if beyond dispute, by several telephone-makers. If we may believe some travellers, it has long been used in Spain for the correspondence of lovers. However this may be, it was not to be found among the scientific appliances of some years ago, and it was even supposed by many persons that the cord consisted of an acoustic tube of slender diameter. Although the instrument has become a child's toy, it has great scientific importance, for it proves that vibrations capable of reproducing speech may be extremely minute, since they can be mechanically transmitted more than a hundred yards.

From the telegraphic point of view, however, the problem of transmitting sounds to a distance was far from being solved in this way, and the idea of applying electricity to this mode of transmission naturally arose as soon as the wonderful effects of electric telegraphy were observed, that is, in the years subsequent to 1839. A surprising discovery made in America by Mr. Page, in 1837, and afterwards investigated by MM. Wertheim, De la Rive, and others, must also have led up to it: for it was observed that a magnetic bar could emit sounds when rapidly magnetised and demagnetised, and these sounds corresponded with the number of currents which produced them. Again, the electric vibrators devised by MM. Macaulay, Wagner, Neef, etc., and adapted to produce musical sounds, between 1847–1852, by MM. Froment and Pétrina, showed that the problem of transmitting sounds to a distance was not insoluble. Yet, up to 1854, no one had ventured to admit the possibility of transmitting speech by electricity, and when M. Charles Bourseul published in that year a paper on the electric transmission of speech, the idea was regarded as a fanciful dream. I confess that I myself thought it incredible, and when I produced the paper in the first edition of my account of the applications of electricity, published in 1854, I felt bound to add that the scheme seemed more than doubtful. Yet, as the paper was thoughtfully written, I had no hesitation in publishing it, affixing the signature of CH. B. Events justified this daring idea, and although it did not include the only principle which could lead to the reproduction of articulate sounds, yet it was the germ of the fertile invention which has made the names of Graham Bell and Elisha Gray famous. For this reason I will again quote M. Charles Bourseul's paper.

'After the telegraphic marvels which can reproduce at a distance hand-writings, or even more or less complicated drawings, it may appear impossible to penetrate further into the region of the marvellous. Yet we will try to advance a few steps further. I have, for example, asked myself whether speech itself may not be transmitted by electricity--in a word, if what is spoken in Vienna may not be heard in Paris. The thing is practicable in this way:--

'We know that sounds are made by vibrations, and are adapted to the ear by the same vibrations which are reproduced by the intervening medium. But the intensity of the vibrations diminishes very rapidly with the distance: so that it is, even with the aid of speaking-tubes and trumpets, impossible to exceed somewhat narrow limits. Suppose that a man speaks near a moveable disk, sufficiently flexible to lose none of the vibrations of the voice, that this disk alternately makes and breaks the currents from a battery: you may have at a distance another disk, which will simultaneously execute the same vibrations.

'It is true that the intensity of the sounds produced will be variable at the point of departure, at which the disk vibrates by means of the voice, and constant at the point of arrival, where it vibrates by means of electricity; but it has been shown that this does not change the sounds. It is, moreover, evident that the sounds will be reproduced at the same pitch.

'The present state of acoustic science does not permit us to declare _à priori_ if this will be precisely the case with syllables uttered by the human voice. The mode in which these syllables are produced has not yet been sufficiently investigated. It is true that we know that some are uttered by the teeth, others by the lips, and so on; but this is all.

'However this may be, observe that the syllables can only reproduce upon the sense of hearing the vibrations of the intervening medium: reproduce precisely these vibrations, and you will reproduce precisely these syllables.

'It is, at all events, impossible in the present condition of science to prove the impossibility of transmitting sound by electricity. Everything tends to show, on the contrary, that there is such a possibility. When the application of electro-magnetism to the transmission of messages was first discussed, a man of great scientific attainments treated the idea as utopian, and yet there is now direct communication between London and Vienna by means of a simple wire. Men declared it to be impossible, but so it is.

'It need not be said that numerous applications of the highest importance will immediately arise from the transmission of speech by electricity. Any one who is not deaf and dumb may use this mode of transmission, which would require no apparatus, except an electric battery, two vibrating disks, and a wire. In many cases, as for example in large establishments, orders might be transmitted

in this way, although transmission by electricity will not be used while it is necessary to go from letter to letter, and to make use of telegraphs which require use and apprenticeship. However this may be, it is certain that in a more or less distant future, speech will be transmitted by electricity. _I have made some experiments in this direction_: they are delicate, and demand time and patience, but _the approximations obtained_ promise a favourable result.'

This description is certainly not full enough to enable us to discern from it the arrangement which would lead to the solution of the problem, and if the vibrations of the disk at the receiving station were to follow from making and breaking the current at the sending-station, under the influence of vibrations caused by the voice, they would only produce musical, and not articulate sounds. Yet the idea was magnificent, as Mr. Preece said, even when he thought it impossible to realise it. Besides, it is easy to see that M. Bourseul himself was not deceived as to the difficulties of the problem, as far as articulate sounds are concerned, for he points out, as we have seen, the difference existing between the simple vibrations which produce musical sounds, and the complex vibrations which cause articulate sounds; but, as he justly said: 'Reproduce at the one end of the line the vibrations of air caused at the other, and speech will be transmitted, however complex the mechanism may be by which it is effected.' We shall presently see how the problem was solved, and it is probable that some attempts had already enabled M. Bourseul to anticipate the solution of the question; but there is nothing in his paper to show what were the means he proposed, so that the discovery of the electric transmission of speech cannot reasonably be ascribed to him, and we do not understand why we should be reproached for having at that time failed to appreciate the importance of a discovery which seemed to be then only within the range of fancy.

It was not until 1876 that the problem of the electric transmission of speech was finally solved, and the discovery has lately given rise to an interesting controversy as to priority between Mr. Elisha Gray, of Chicago, and Mr. Graham Bell, on which we must say a few words.

As early as 1874 Mr. Elisha Gray was occupied with a system of musical telephone, which he wished to apply to manifold telegraphic transmissions, and the investigations which he made, in order to establish this system under the best possible conditions, gave him a glimpse of the possibility of transmitting articulate words by electricity. While carrying on his experiments on the telegraphic system, he arranged in fact, about the 15th January, 1876, a system of _speaking telephone_, and he deposited the specification and drawings in the American Patent Office, in the form of a _caveat_ or provisional specification. The deposit was made on the 14th February, 1876: on the very same day, Mr. Graham Bell also deposited, in the American Patent Office, a request for a patent in which he spoke of an instrument of the same kind, but with special application to simultaneous telegraphic transmissions by means of a telephonic apparatus; and the few words which could, in this specification, refer to a telephone with articulate sounds, applied to an instrument which, by Mr. Bell's own admission, had not produced any satisfactory results. In Mr. Gray's _caveat_, on the contrary, the application of the instrument to the electric transmission of speech alone is indicated, the description of the system is complete, and the drawings which accompany it are so exact, that a telephone made from them would work perfectly: this was proved by Mr. Gray himself, when, some time afterwards, he finished his instruments, which differed in no respect from the one described in Mr. Bell's statement as worked by a battery. On these grounds Mr. Elisha Gray would certainly have obtained the patent, if the expiration of his _caveat_ had not been the result of an omission of form in the Patent Office, which, as we know, decides the priority of inventions in America. An action on the ground of this omission has lately been brought against Mr. Bell, in the Supreme Court of the American Patent Office, to set aside the patent granted to him. If Mr. Gray did not appeal before, it was because he was then wholly occupied with experiments on the system of harmonic telephone, applied to telegraphic communication, and he had no time to attend to the matter.

However this may be, Mr. Bell did not begin to give serious attention to the speaking telephone until he had obtained his patent, and his efforts were soon crowned with success: a few months later, he exhibited his speaking telephone at Philadelphia, which has from that time attracted so much public attention, and which, when perfected in a practical point of view, reached Europe in the autumn of 1877 under the form we know.

To complete this summary account of the telephone, we ought to say that since its success a good many claims of priority have arisen, as if by enchantment. Mr. John Camack, of English origin, has among others claimed the invention of the telephone, not merely relying on the description he gave of the instrument in 1865, but on the drawings he executed; he even adds, that if he had not lacked means for its construction, this would have been the date of the discovery of the telephone. A similar pretension has been put forward by Mr. Dolbear, a fellow countryman of Mr. Bell, of whose claim we shall speak presently.

Signor Manzetti, of Aosta, says the same thing, asserting that his telephonic invention was described in several newspapers of 1865, among others in 'Le Petit Journal,' of Paris, on the 22nd November, 1865; 'Il Diritto' at Rome, 16th July, 1865; 'L'Echo

d’Italia,’ New York, 9th August, 1865; ‘L’Italia,’ Florence, 10th August, 1865; ‘La Comuna d’Italia,’ Genoa, 1st December, 1865; ‘La Verità,’ Novara, 4th January, 1866; ‘Il Commercio,’ Genoa, 6th January, 1866. It is true that no description of the system was given, and that the journals in question only asserted that experiments had been made, which proved that the practical solution of the problem of transmitting speech by electricity became possible by this system. At any rate M. Charles Bourseul must still have the credit of the priority of the idea, and, in our opinion, all claims made after the fact only merit slight consideration.

Before considering Bell’s telephone, and the different modifications which have been applied to it, it seems worth while, in order to make the reader perfectly familiar with these kinds of instruments, to study the electro-musical telephones which preceded it, and especially that of M. Reiss, which was made in 1860, and became the starting point of all the others. We shall find that these instruments have very important applications, and that telegraphy will probably be one day much advanced by their use.

MUSICAL TELEPHONES.

Telephone of M. Reiss.--This telephone is, as far as the reproduction of sound is concerned, based upon Mr. Page’s discoveries in 1837, and, as regards electric transmission, it is based on the vibrating membrane of which Mr. L. Scott made use in his phonautograph, in 1855. This instrument is composed, like telegraphic systems, of two distinct parts, a sender and a receiver, as represented in fig. 1.

[Illustration: FIG. 1.]

The sender was virtually composed of a sounding box K, having on its upper surface a large circular opening, across which a membrane was stretched, and in its centre there was fitted a thin disk of platinum _o_, above which a metallic point _c_ was fixed, and this, together with the disk, constituted the contact-breaker. On one face of the sounding-box K, there was a sort of speaking-tube, for the purpose of collecting the sound, and directing it to the interior of the box, in order that it might then react upon the membrane. Part of the box K is broken away in the plate, in order that the different parts of which it is made may be seen.

The rods _a_, _c_, which support the platinum point _b_, are in metallic contact with a Morse key _t_, placed on the side of the box K, and with an electro-magnet A, which belongs to a telegraphic system, intended to exchange the signals required to start the action of the two instruments at their respective stations.

The receiver consists of a sounding-box B, on which rest two supports _d_, _d_, bearing an iron rod of the thickness of a knitting needle. An induction coil of insulated wire _g_ is wound round this rod, and the whole is enclosed by the lid D, which concentrates the sound already increased by the sounding-box: for this purpose the box is provided with two openings below the coil.

The circuit is completed through the primary of this coil by the two terminals 3 and 4, and a Morse key _t_ is placed at the side of box B, in order to exchange signals.

In order to work this system, the speaking instrument should be placed before the opening T, and this instrument may be a flute, a violin, or even the human voice. The vibrations of air occasioned by these instruments cause the telephonic membrane to vibrate in unison, and the latter, rapidly moving the platinum disk _o_ to and from the point _b_, causes a series of breaks in the current, which are repeated in the iron wire _d d_, and transformed into metallic vibrations, of which the number is equal to that of the sounds successively produced.

According to this mode of action, the possibility of transmitting sounds with their relative value becomes intelligible: but it is equally clear that sounds thus transmitted will not have the _timbre_ of those which produce them, since the _timbre_ is independent of the number of vibrations, and it must be added that the sounds produced by M. Reiss’s instrument were as shrill as those of a child’s penny trumpet, and by no means attractive. The problem of transmitting musical sounds by electricity was, however, really solved, and it can be said with truth that an air or a melody could be heard at any given distance.

The invention of this telephone dates, as we have seen, from 1860, and Professor Heisler speaks of it in his treatise of technical physics, published at Vienna in 1866; he even asserts, in the article which he devotes to the subject, that although the instrument was still in its infancy, it was capable of transmitting vocal melodies, and not merely musical sounds. The system was afterwards perfected by M. Van der Weyde, who, after reading the account published by M. Heisler, sought to make the box of the sender more sonorous, and to strengthen the sounds produced by the receiver. He writes as follows in the ‘American Scientific Journal:’

‘In 1868, I caused two telephones to be made, similar to those I have described, and I exhibited them at a meeting of the Polytechnic Club of the American Institute. The transmitted sounds were produced at the farthest extremity of the Cooper Institute, quite outside the hall in which the audience sat: the receiver was placed on a table in the hall itself. The vocal airs were faithfully reproduced, but the sound was rather weak and nasal. I then tried to improve the instrument, and I first obtained stronger vibrations in the box K by causing reverberation from the sides of the box, by means of hollow partitions. I next intensified the sounds produced by the receiver, by introducing several iron wires into the coil, instead of one. These improvements were submitted to the meeting of the American Association for the Advancement of Science, which was held in 1869, and it was considered that the invention contained the germ of a new method of telegraphic transmission which might lead to important results.’ This opinion was soon afterwards justified by the discoveries of Bell and Elisha Gray.

Messrs. Cecil and Leonard Wray’s Telephone.--This system, represented in figs. 2 and 3, is simply an improvement on that of M. Reiss, with the object of intensifying the effects produced. The sender is provided with two membranes, instead of one; and its receiver, instead of being formed of a single iron wire covered with a magnetising coil, is composed of two distinct coils H, H′ (fig. 2), placed in the same straight line, and within which are two iron rods. These rods are fastened by one of their ends to two copper disks A, B; these disks are maintained in a fixed position by screws I, I′, and the two other extremities of the rods, between the coils, are opposite each other, not touching, but divided by a very small interval. The instrument is set upon a sounding-box, in which there is a hole T in the space corresponding to the interval between the coils: these coils communicate with four terminals, which are connected with the electric current in such a way that the adjacent poles of the two rods are of opposite polarity, thus forming a single magnet, divided in the centre. It seems that by this arrangement the sound produced becomes much more distinct.

[Illustration: FIG. 2.]

[Illustration: FIG. 3.]

The form of the sender also is somewhat different from the one we have previously described: the upper part, instead of being horizontal, is rather inclined, as it appears in fig. 3, and the opening E through which the sound has to communicate with the vibrating membrane, occupies a great part of the upper surface of the box, which consequently appears to be somewhat oblique. The second membrane G, which is of caoutchouc, forms a sort of partition which divides the box in two, starting from the upper end of the opening: the inventor states that this will protect the outer membrane D from the breath and other injurious effects, while increasing the force of the vibrations produced on the first membrane, as in a drum. The contact-breaker itself also differs from the one in M. Reiss’s instrument. The platinum disk _b_ is only placed in circuit by means of two slender wires of platinum or steel, which are immersed in two small cups, filled with mercury, and connected with the circuit. In this way, the movements of the membrane D are free, and its vibration is rendered more easy.

The circuit is also broken by a little platinum point resting on a lever with a spring-joint, K H, which is above the disk: one end of the lever, which is fixed below a kind of Morse key M I, makes it possible to close the circuit with the hand, so as to give the signal for setting the apparatus to work.

Electric Harmonica.--Long before M. Reiss’s invention, and consequently still longer before that of Mr. Elisha Gray, I mentioned a sort of electric harmonica, and described it as follows in the first edition of my ‘Exposé des applications de l’Electricité,’ published in 1853:--

‘The power possessed by electricity to set metallic plates in motion and cause their vibration has been used for the production of distinct sounds, which can be combined and harmonised; but in addition to this purely physical application, electro-magnetism has come to the aid of certain instruments, such as pianos, organs, &c., rendering them capable of being played at a distance. So that this extraordinary force may be turned to account in arts which are apparently the least susceptible of any application of electricity.

‘We have already spoken of M. de la Rive’s contact-breaker. It is, as we know, an iron disk, soldered to a steel spring, and maintained in a fixed position opposite to an electro-magnet by another spring in connection with one branch of the current. As the other branch, after passing into the wire of the electro-magnet, terminates in the iron disk itself, the electro-magnet is only active at the moment when the disk touches the terminal spring; at the moment of leaving it, the magnetism ceases, and the iron disk returns to its normal position, and then leaves it again. In this way a vibration is produced, rapid in proportion to the small size of the vibrating disk, and to the greatness of the force produced by the approach of the disk to the electro-magnet.

‘In order to increase the acuteness of the sounds, one or other of these expedients must be employed. The simplest way is to use a screw which can be tightened or relaxed at pleasure, and which in this manner removes the vibrating disk to a greater or less distance from the electro-magnet. This is the case in M. Froment’s instrument, and by this means he has obtained sounds of extraordinary acuteness, although not unpleasant to the ear.

‘M. Froment has not applied the apparatus to a musical instrument, but it is evident that it would be easy to do so; it would only be necessary to make the notes of a key-board act on metallic levers, of a length corresponding to the position required by the disk for the vibration of different tones. These different levers, resting on the disk, would act as a point of contact, but the point would vary in position, according to the touch.

‘If the current were constant, such an instrument would certainly have many advantages over the pipe instruments which are in use, since the vibration might be prolonged at will in the case of each note, and the sounds would be softer; unfortunately the irregular action of the battery makes it difficult in practice. These kinds of instruments are therefore only used as a means of regulating by ear the force of the battery, a much more convenient regulator than the rheometers, since it is possible to estimate by them the variations of the battery during an experiment without any distraction of the mind.’

In 1856 M. Pétrina, of Prague, invented an analogous arrangement, to which he gave the name of electric harmonica, although, strictly speaking, he had not thought of it as a musical instrument. This is what I have said on the subject in vol. iv. of the second edition of my ‘Exposé des applications de l’Electricité,’ published in 1859:--

‘The principle of this instrument is similar to that of Neef’s rheotome, in which the hammer is replaced by slender rods, whose vibrations produce a sound. Four of these rods are placed side by side, and when moved by keys, and arrested by levers, produce combined sounds of which the origin may be easily shown.’

It is true that nothing is said in this passage of the capability possessed by these instruments of being played at a distance; but this idea was quite legitimate, and German periodicals assert that it was accomplished by M. Pétrina even before 1856. It was the result of what I said at the outset: ‘that electro-magnetism may come to the aid of certain instruments, such as pianos, organs, &c., _in order to enable them to be played at a distance_,’ and I also pointed out the expedients employed for the purpose, and even for setting them at work, under the influence of a small musical box. I did not, however, ascribe importance to the matter, and it is only by way of historical illustration that I speak of these systems.

Telephone by Mr. Elisha Gray, of Chicago.--This system, invented in 1874, is in reality only an instrument of the nature of those which preceded it, but with important modifications, which made it possible to apply it usefully to telegraphy. In an early model, he made use of an induction coil, with two helices, one over the other: the contact-breaker, which was vibrating, was multiple, and so arranged as to produce vibrations numerous enough to emit sounds. These sounds may, as we have seen, be modified by this arrangement, according to the mode in which the instrument is adjusted, and if there are a certain number of such contact-breakers side by side, with vibrating disks so ordered as to produce the different notes of the scale on several octaves, it becomes possible, by a combination of certain notes, to execute on this new kind of instrument a piece of music such as may be produced by an harmonium, an accordion, or any other instrument with blowers. The contact-breakers are set in motion by means of the primary current of the induction coil, as it circulates through one or other of the electro-magnets of these contact-breakers, actuated by the lowering of the notes of a key-board connected with them, and the secondary currents which arise in the coil, in consequence of the interruptions in the primary currents, transmit the corresponding vibrations to a remote receiver. There is an analogy between this instrument and the telephones of which we have already spoken by Reiss and Wray, but the effect is increased by Mr. Gray’s modifications.

We represent in fig. 4 the arrangement of the first system. The vibrators are A and A′, the key-board M and M′, the induction coil B, and the receiver C. This receiver consists, as we see, of a simple electro-magnet N N′: above its poles there is a metal cylindrical case C, of which the bottom is made of iron, to serve as an armature. This box, like a violin, is pierced with two holes in the form S, to serve as a sounding-board; and Mr. Elisha Gray has ascertained that the molecular motion which takes place in the magnetic core and its armature, under the influence of alternate magnetisation and demagnetisation, sufficed to produce vibrations corresponding to the velocity of these alternations, and to emit sounds which became audible when they were magnified by the sounding-board.

[Illustration: FIG. 4.]

It is quite intelligible that the effect obtained in this system might be reproduced, if, instead of contact-breakers or electric rheotomes, mechanical contact-breakers were used at the sending station, so arranged as to furnish the requisite number of breaks in the current which communicates the vibrations of the different notes of the scale. In this way also it would be possible to dispense with the induction coil, by causing the current which has been broken by the mechanical contact-breaker to react upon the receiver. Mr. Elisha Gray has moreover made a different arrangement of this telephonic system, which he has applied to telegraphy for simultaneous electric transmissions, of which we shall speak presently.

If we may believe Mr. Elisha Gray, the vibrations transmitted by the secondary currents would be capable, by the intervention of the human body, of causing the sounds to be reproduced at a distance by conducting disks, which vibrate readily, and are placed on a sounding-box. In this way musical sounds may be evoked from copper cylinders placed upon a table, from a metallic disk fastened to a kind of violin, from a membrane stretched on a drum, or from any other resonant substance, by touching any of these objects with one hand, while holding the end of the line with the other. These sounds, of which the quality must vary with the substance touched, would reproduce the transmitted note with the precise number of vibrations which belong to it.[1]

Mr. Varley's Telephone.--This is, strictly speaking, merely a musical telephone of the same kind as that of Mr. Gray, but the arrangement of the receiver is original and interesting. This part of the instrument essentially consists of a drum of large size (three or four feet in diameter), within which is a condenser formed of four sheets of tinfoil, divided by sheets of some insulating material, and with a surface of about half the size of the drum. The plates of the condenser are placed parallel to the membranes of the drum, and very little removed from its surface.

If an electric charge is communicated to one of the series of conducting plates of the condenser, those which correspond to it are attracted, and if they were movable they might communicate to the intervening strata of air a movement which, on reaching the membranes of the drum, might, by a series of charges in rapid succession, cause the membranes to vibrate, and thus produce sounds: these sounds would correspond to the number of charges and discharges which had occurred. Since these charges and discharges are determined by the contact of the two plates of the condenser, at the extremities of the secondary circuit of an induction coil, of which the primary circuit has been duly broken, it becomes evident that, in order to cause the drum to emit any given sound, it will be enough to produce the number of vibrations in the contact-breaker of the induction coil which are required for this sound.

The means employed by Mr. Varley to produce these interruptions are the same which are in use in several electrical instruments, and especially in chronographs--an electro-magnetic tuning-fork, regulated so as to emit the sound required. This tuning-fork may, by acting as contact-breaker, react on the primary current of the induction coil; if the number of the tuning-forks equals that of the musical notes which are to be transmitted, and if the electro-magnets which set them in motion are connected with the key-board of a piano, it would be possible to transmit a melody to a distance by this system, as well as by that of Mr. Elisha Gray.

The peculiarity of this system consists in the reproduction of sounds by the action of a condenser, and we shall presently see that this idea, adopted by Messrs. Pollard and Gamier, led to interesting results.

Singing Condenser of MM. Pollard and Garnier.--This instrument, which astonishes all who hear it, attracted public attention in London some time ago. It is difficult to say why its fame was not greater, since much attention has been bestowed on less curious instruments. It is a fact that we have been able, thanks to MM. Pollard and Garnier, to hear songs issue from a sort of copy-book, so as to become audible throughout the room. The songs thus reproduced are certainly not always perfectly true; yet when the person who sings into the sender is a musician, and understands how to make use of it, the condenser in question will emit sounds somewhat resembling those of the violoncello or the hautbois.

The singing instrument consists of a condenser K, formed of thirty sheets of paper, laid one over the other, from nine to thirteen centimètres in thickness: between these, twenty-eight sheets of tinfoil, from six to twelve centimètres thick, are intercalated, so joined as to form the two plates of the condenser. For this purpose the pair sheets are joined together at one end of the copy-book, and the odd sheets at the other end. This system is fastened to a stiff _carton_, after taking care to bind it with a strip of paper, and the sheets of tinfoil are joined to the two ends of the condenser by two copper rims D, D, which are provided with terminals for the circuit wire, and in this way the singing instrument is constructed. A somewhat heavy weight, placed upon the condenser to compress the sheets, does not in any way prevent it from working; and this vitiates the theory first put forward to explain its effects, that the sheets were moved by attraction.

[Illustration: FIG. 5.]

The sending instrument consists of a sort of telephone without a handle, E, of which the vibrating disk is formed of a very thin plate of tin. A cylindrical piece of carbon C is fastened to its centre, and is supported by another cylinder of the same material H. This rests on a transverse piece of wood A B, jointed on the side A, on the edge opposite to the box, by means of a regulating screw V. An arched spring R (the end of a watch spring) placed across this piece of wood gives it a certain elasticity beneath the pressure, and this elasticity is necessary in order that the instrument may act properly, and it thus becomes a sort of microphone with a diaphragm.

The tin plate is put into communication with one pole of a battery P, of six Leclanché cells, and the lower carbon cylinder H corresponds to the primary helix of an induction coil M, previously connected with the second pole of the battery: Finally, the two extremities of the secondary helix of the coil, _a_ and _b_, are in immediate connection with the two plates D, D, of the condenser.

This secondary helix should consist of twenty strands of wire No. 32, covered with silk, and the primary helix is made of five strands of wire No. 16. The length of the coil should not exceed seven centimètres and the diameter of the core of fine iron wire ought to be about one centimètre.

In order to produce song on the condenser, the sender must be so regulated that the two carbons C and H do not touch each other in their normal condition, but they should be so close that in singing the vibrations of the disk L L may effect the needful contacts. The adjustment can be easily made by the touch, and by uttering the same note until it is repeated by the condenser. If three notes, given in succession, are faithfully reproduced, the instrument may be assumed to be properly regulated, and, in order to make it work, it is enough to apply the mouth to the mouthpiece as it is applied to a reed pipe.

In order to obtain a satisfactory result, the disk of the instrument must be heard to vibrate, as in a _flûte à l'oignon_. Instead of carbons, contacts of platinum may be used; but when arranged as we have described, the instrument may be employed for several purposes, as we shall see presently. This instrument is made by MM. Chardin and Prayer. M. Janssens has made the system more portable by fastening the sender, represented in fig. 5, to a handle in which the induction coil is placed: the instrument then resembles an ordinary telephone, and the vibration of the diaphragm is made more easy by piercing two holes in it. On the side of the sending-box, above and below the diaphragm, there are binding screws in connection with the end of the handle, since the instrument may be used as an ordinary telephonic sender, and even as a telephonic receiver.

SPEAKING TELEPHONES.

We have seen that the telephones just described can only transmit musical sounds, since they can merely repeat simple vibrations, in greater or less number, it is true, but not in simultaneous combinations like those which reproduce articulate sounds. Up to the time of Mr. Bell's invention, the transmission of speech could only take place with the aid of acoustic tubes, or of the string telephones of which we have spoken. Although these instruments have no connection with the object of our study in this work, we have thought it necessary to say a few words about them, since they may sometimes be combined with electric telephones, and also represent the first stage of the invention.

String Telephones.--These instruments, which have flooded the cities of Europe for several years, since the date of the invention was 1867, are interesting in themselves, and we are surprised that they have not hitherto taken a place in the collections of physical science. They are made of two metal or cardboard tubes, in the form of a cylindrical cone: one end is closed by a tightly stretched membrane of parchment, in the centre of which the cord or string intended to connect the two cylinders is fastened by a knot. When two such tubes are connected in this way, and the cord is tightly stretched, as in fig. 6, it is only necessary to apply one tube to the ear, while another speaks into the opening of the other tube: the words spoken by the latter are instantly transmitted, and it is even possible to converse in quite an undertone. Under these conditions the vibrations of the membrane affected by the voice are mechanically transmitted to the other membrane by the string, which, as Robert Hooke declared in 1667, is a better transmitter of sound than the air. In this way it is possible to communicate at a distance of 170 yards, and the size and nature of the cord have some influence. The sellers of these instruments say that the best results are obtained from silken cords, and the worst from those made of hemp. Cords of plaited cotton are usually employed for the sake of cheapness.

[Illustration: FIG. 6.]

In some patterns, the tubes are so arranged as to present, between the membrane and the mouth, a diaphragm pierced with a hole, and the instrument somewhat resembles a bell with its base bored and closed again a little above the parchment membrane;

but I have not observed that this pattern is decidedly superior to the others.

It has also been asserted that horn-shaped tubes of nickel silver are to be preferred, of which I am equally doubtful. At any rate, these instruments have produced unexpected results; and although their practical use is very limited, they are interesting from a scientific point of view, and are instructive toys for children.

Mr. Millar, of Glasgow, declares that the effect produced by these telephones depends very much on the nature of the string, the way in which it is attached, and the way in which the membrane is fastened to the mouthpiece.

Improvements made in the String Telephone.--The amazing effects of the Bell telephones have lately brought the string telephones, which were only regarded as children's toys, again into fashion. Since they have made it possible to transmit to several persons the words reproduced by an electric telephone, means have been sought for combining them usefully with the latter, and the best mode of making them speak on a string presenting several angles has been sought for: it has been shown that, under the usual conditions, these instruments only speak distinctly when the string is stretched in a right line. To solve this problem, it occurred to M. A. Bréguet to make use of a sort of tambourine for the supports, with the string passed through their centre; the sound conveyed by that part of the string which is in connection with the speaking-horn causes the membrane of the tambourine to vibrate, which again communicates the vibration to the next portion of string. In this way the angles may be multiplied at will, and the string may be supported throughout the length compatible with this kind of telephone, which does not exceed 112 yards.

M. A. Bréguet has also invented a system of relays to accomplish the same object. He makes the strings terminate in two membranes which close the two openings of a brass cylinder. The sounds reproduced on one of these membranes react upon the other, which vibrates under its influence, as if it were affected by the voice. The cylinder then acts as an ordinary acoustic tube, and its form may be varied at pleasure.

M. A. Badet, on February 1, 1878, succeeded in making string telephones in an analogous way, and he used parchment stretched upon frames which acted as resonant boards. The string was fixed in the centre of the membrane, and made with it the angle desired.

Several scientific men, among others Messrs. Wheatstone, Cornu, and Mercadier, have long been occupied about these ways of transmission by wire, and Messrs. Millar, Heaviside, and Nixon have lately made some interesting experiments, on which we must say a few words. Mr. Millar ascertained that by means of a telegraphic wire, stretched and connected by two copper wires with two vibrating disks, musical sounds might be conveyed to a distance exceeding 160 yards, and that by stretching these wires through a house, and connecting them with mouth-and-ear holes in different rooms, communication between them became perfectly easy.

For the vibrating disks he employed wood, metal, or gutta-percha, in the form of a drum, with wires fixed in the centre. The sound seems to become more intense in proportion to the thickness of the wire.

Messrs. Heaviside and Nixon, in their experiments at Newcastle-on-Tyne, have ascertained that the most effective wire was No. 4 of the English gauge. They employed wooden disks ■ inch in thickness, and these may be placed in any part of the length of the wire. When the wire was well stretched and motionless, it was possible to hear what was said at a distance of 230 yards, and it seems that Mr. Huntley, by using very thin iron diaphragms, and by insulating the line wire on glass supports, was able to transmit speech for 2,450 feet, in spite of the zigzags made by the line on its supports.

Mr. Graham Bell's Electric Telephone.--Telephonic instruments were at this stage when Bell's telephone was shown at the Philadelphia Exhibition of 1876. Sir William Thompson did not hesitate to call it 'the wonder of wonders,' and it instantly attracted universal attention, although there was at first much incredulity as to its genuineness. This telephone, in fact, reproduced articulate words, a result which surpassed all the conceptions of physicists. In this case it was no longer a conception, to be treated as visionary until there was proof to the contrary: the instrument spoke, and even spoke so loudly that it was not necessary to apply the ear. Sir William Thompson spoke to this effect on the subject at the meeting of the British Association at Glasgow in September 1876:--

'In the department of telegraphs in the United States I saw and heard Mr. Elisha Gray's electric telephone, of wonderful construction, which can repeat four despatches at the same time in the Morse code, and, with some improvements in detail, this instrument is evidently capable of a fourfold delivery. In the Canadian department I heard "To be or not to be? There's the rub," uttered through a telegraphic wire, and its pronunciation by electricity only made the rallying tone of the monosyllables more

emphatic. The wire also repeated some extracts from New York papers. With my own ears I heard all this, distinctly articulated through the slender circular disk formed by the armature of an electro-magnet. It was my fellow-juryman, Professor Watson, who, at the other extremity of the line, uttered these words in a loud and distinct voice, while applying his mouth to a tightly stretched membrane provided with a small piece of soft iron, which executed movements corresponding to the sound vibrations of the air close to an electro-magnet introduced into the circuit. This discovery, the wonder of wonders in electric telegraphy, is due to a young fellow-countryman of our own, Mr. Graham Bell, a native of Edinburgh and now naturalised in New York.

'It is impossible not to admire the daring invention by which we have been able to realise with these simple expedients the complex problem of reproducing by electricity the tones and delicate articulations of voice and speech; and it was necessary, in order to obtain this result, to find out the means of varying the intensity of the current in the same proportion as the inflections of the sound emitted by the voice.'

If we are to believe Mr. Graham Bell, the invention of the telephone was not due to a spontaneous and fortunate conception: it was the result of his long and patient studies in acoustic science, and of the labours of the physicists who preceded him.[2] His father, Mr. Alexander Melville Bell, of Edinburgh, had studied this science deeply, and had even succeeded in representing with great ingenuity the adaptation of the vocal organs for the emission of sound. It was natural that he should instil a taste for his favourite studies into his son's mind, and they made together numerous researches in order to discover the relations which exist between the different elements of speech in different languages, and the musical relations of vowels. It is true that several of these researches had been made by M. Helmholtz, and under more favourable conditions; but these studies were of great use to Mr. Bell when he was afterwards occupied with the telephone, and Helmholtz's experiments, which he repeated with one of his friends, Mr. Hellis of London, concerning the artificial reproduction of vowels by means of electric tuning-forks, launched him into the study of the application of electricity to acoustic instruments. He first invented a system of an electric harmonica with a key-board, in which the different sounds of the scale were reproduced by electric diapasons of different forms, adapted to different notes, and which, when set in motion by the successive lowering of the keys, could reproduce sounds corresponding to the notes touched, just as in an ordinary piano.

He next, as he tells us, turned his attention to telegraphy, and thought of making the Morse telegraphs audible by causing the electro-magnetic organ to react on sounding contacts. It is true that this result had already been obtained in the sounders used in telegraphy, but he thought that by applying this system to his electric harmonica, and by employing such an intensifying instrument as Helmholtz's resonator at the receiving station, it would be possible to obtain through a single wire simultaneous transmissions which should be due to the action of the voice. We shall see presently that this idea was realised almost at the same time by several inventors, among others by M. Paul Lacour, of Copenhagen, Mr. Elisha Gray, of Chicago, and Messrs. Edison and Varley.

Mr. Bell's study of electric telephones really dates from this time, and he passed from complex to simple instruments, making a careful study of the different modes of vibration which arise from different modes of electric action. The following is an abstract, with the omission of more technical details, of the paper read by Mr. Bell to the Society of Telegraphic Engineers, London, October 31, 1877.

If the intensity of an electric current is represented by the ordinates of a curve, and the duration of breaks in the current by the abscissæ, the given curve may represent the waves of the positive or negative current respectively, above and below the line of X, and these waves will be more or less accentuated, just as the transmitted currents are more or less instantaneous.

If the currents which are interrupted to produce a sound are quite instantaneous in their manifestation, the curve represents a series of isolated indentations, as we see in fig. 7; and if the interruptions are so made as only to produce differences of intensity, the curve is presented under the form of fig. 8. Finally, if the emissions of current are so ordered that their intensity alternately increases and diminishes, the curve takes the form represented in fig. 9. In the first case, the currents are _intermittent_; in the second, _pulsatory_; in the third case, they are _undulatory_.

[Illustration: FIG. 7.]

[Illustration: FIG. 8.]

[Illustration: FIG. 9.]

These currents are necessarily positive or negative, according to their position above or below the line _x_, and if they are alternately reversed, the curves present the form given in fig. 10, curves which essentially differ from the first, not merely in the

different form of the indentations, but especially in the suppression of the extra current, which is always found in the pulsatory and undulatory currents.

[Illustration: FIG. 10.]

The two former systems of currents have long been in use for the electric transmission of musical sounds, of which we have an interesting example in Reiss's telephone already described. But Mr. Bell claims to have been the first to employ the undulatory currents, which made it possible to solve the problem of transmitting speech.[3] In order to estimate the importance of this discovery, it will be enough to analyse the effects produced with these different systems of currents when several notes of varying pitch are to be combined.

Fig. 7 shows a combination in which the styles _a_, _a′_, of two sending instruments cause the interruption of the current from the same battery B, so that the given vibrations should be between them in the relation of a tierce major, that is in the relation of four to five. Under such conditions, the currents are intermittent, and four contacts of _a_ are produced in the same space of time as the five contacts of _a′_, and the corresponding electric intensities will be represented by the indentations we see in A^2 and in B^2: the combination of these intensities A^2 + B^2 will produce the indentations at unequal intervals which may be observed on the third line. It is evident that although the current maintains a uniform intensity, there is less time for the breaks when the interrupting styles act together than when they act separately, so that when there are a number of contacts effected simultaneously by styles working at different degrees of velocity, the effects produced will have the effect of a continuous current. The maximum number of distinct effects which can be produced in this way will, however, greatly depend on the relation which exists between the durations of the make and break of the current. The shorter the contacts are, and the longer the breaks, the more numerous will be the effects transmitted without confusion, and _vice versâ_.

By the aid of pulsatory currents the transmission of musical sounds is effected in the way indicated in fig. 8, and it is seen that when they are produced simultaneously, the result A^2 + B^2 is analogous to that which would be produced by a continuous current of minimum intensity.

In the case of undulatory currents the result is different, but in order to produce them it is necessary to have recourse to inductive effects, and fig. 9 indicates the manner in which the experiment should be made. In this case, 'the current from the battery B is thrown into waves by the inductive action of iron or steel reeds M, M, vibrated in front of electro-magnets _e_, _e_, placed in circuit with the battery: A^2 and B^2 represent the undulations caused in the current by the vibration of the magnetised bodies, and it will be seen that there are four undulations of B^2 in the same time as five undulations of A^2. The resultant effect upon the main line is expressed by the curve A^2 + B^2, which is the algebraical sum of the sinusoidal curves A^2 and B^2. A similar effect is produced when reversed undulatory currents are employed, as in fig. 10, where the current is produced by the vibration of permanent magnets united upon a circuit, without a voltaic battery.

'It will be understood from figs. 9 and 10 that the effect of transmitting musical signals of different pitches simultaneously along a single wire is not to obliterate the vibratory character of the current, as in the case of intermittent and pulsatory currents, but to change the shapes of the electrical undulations. In fact, the effect produced upon the current is precisely analogous to the effect produced in the air by the vibration of the inducing bodies M, M′. Hence it should be possible to transmit as many musical tones simultaneously through a telegraph wire as through the air.'

[Illustration: FIG. 11.]

After applying these principles to the construction of a telegraphic system for multiple transmissions, Mr. Bell lost no time in making use of his researches to improve the vocal training of deaf mutes. 'It is well known,' he said, 'that deaf mutes are dumb merely because they are deaf, and that there is no defect in their vocal organs to incapacitate them from utterance. Hence it was thought that my father's system of pictorial symbols, popularly known as visible speech, might prove a means whereby we could teach the deaf and dumb to use their vocal organs and to speak. The great success of these experiments urged upon me the advisability of devising methods of exhibiting the vibrations of sound optically, for use in teaching the deaf and dumb. For some time I carried on experiments with the manometric capsule of Koenig, and with the phonautograph of Léon Scott. The scientific apparatus in the Institute of Technology in Boston was freely placed at my disposal for these experiments, and it happened that at that time a student of the Institute of Technology, Mr. Maurey, had invented an improvement upon the phonautograph. He had succeeded in vibrating by the voice a stylus of wood about a foot in length which was attached to the membrane of the phonautograph, and in this way he had been enabled to obtain enlarged tracings upon a plane surface of smoked glass. With this apparatus I succeeded in

producing very beautiful tracings of the vibrations of the air for vowel sounds. Some of these tracings are shown in fig. 11. I was much struck with this improved form of apparatus, and it occurred to me that there was a remarkable likeness between the manner in which this piece of wood was vibrated by the membrane of the phonautograph and the manner in which the _ossiculæ_ of the human ear were moved by the tympanic membrane. I determined therefore to construct a phonautograph modelled still more closely upon the mechanism of the human ear, and for this purpose I sought the assistance of a distinguished aurist in Boston, Dr. Clarence J. Blake. He suggested the use of the human ear itself as a phonautograph, instead of making an artificial imitation of it. The idea was novel, and struck me accordingly, and I requested my friend to prepare a specimen for me, which he did. The apparatus, as finally constructed, is shown in fig. 12. The _stapes_ was removed, and a stylus of hay about an inch in length was attached to the end of the _incus_. Upon moistening the _membrana tympani_ and the _ossiculæ_ with a mixture of glycerine and water, the necessary mobility of the parts was obtained; and upon singing into the external artificial ear the stylus of hay was thrown into vibration, and tracings were obtained upon a plane surface of smoked glass passed rapidly underneath. While engaged in these experiments I was struck with the remarkable disproportion in weight between the membrane and the bones that were vibrated by it. It occurred to me that if a membrane as thin as tissue paper could control the vibration of bones that were, compared to it, of immense size and weight, why should not a larger and thicker membrane be able to vibrate a piece of iron in front of an electro-magnet, in which case the complication of steel rods shown in my first form of telephone, could be done away with, and a simple piece of iron attached to a membrane be placed at either end of the telegraphic circuit?

[Illustration: FIG. 12.]

‘For this purpose I attached the reed A (fig. 13) loosely by one extremity to the uncovered pole _h_ of the magnet, and fastened the other extremity to the centre of a stretched membrane of goldbeaters’ skin _n_. I presumed that upon speaking in the neighbourhood of the membrane _n_, it would be thrown into vibration and cause the steel reed A to move in a similar manner, occasioning undulations in the electrical current that would correspond to the changes in the density of the air during the production of the sound; and I further thought that the change of the intensity of the current at the receiving end would cause the magnet there to attract the reed A′ in such a manner that it should copy the motion of the reed A, in which case its movements would occasion a sound from the membrane _n′_ similar in _timbre_ to that which had occasioned the original vibration.

[Illustration: FIG. 13.]

[Illustration: FIG. 14.]

‘The results, however, were unsatisfactory and discouraging. My friend Mr. Thomas A. Watson, who assisted me in this first experiment, declared that he heard a faint sound proceed from the telephone at his end of the circuit, but I was unable to verify his assertion. After many experiments attended by the same only partially successful results, I determined to reduce the size and weight of the spring as much as possible. For this purpose I fastened a piece of clock spring, about the size and shape of my thumbnail, firmly to the centre of the diaphragm, and had a similar instrument at the other end (fig. 14); we were then enabled to obtain distinctly audible effects. I remember an experiment made with this telephone, which at the time gave me great satisfaction and delight. One of the telephones was placed in my lecture-room in the Boston University, and the other in the basement of the adjoining building. One of my students repaired to the distant telephone to observe the effects of articulate speech, while I uttered the sentence, “Do you understand what I say?” into the telephone placed in the lecture-hall. To my delight an answer was returned through the instrument itself, articulate sounds proceeded from the steel spring attached to the membrane, and I heard the sentence, “Yes, I understand you perfectly.” It is a mistake, however, to suppose that the articulation was by any means perfect, and expectancy no doubt had a great deal to do with my recognition of the sentence; still, the articulation was there, and I recognised the fact that the indistinctness was entirely due to the imperfection of the instrument. I will not trouble you by detailing the various stages through which the apparatus passed, but shall merely say that after a time I produced the form of instrument shown in fig. 15, which served very well as a receiving telephone. In this condition my invention was exhibited at the Centennial Exhibition in Philadelphia. The telephone shown in fig. 14 was used as a transmitting instrument, and that in fig. 15 as a receiver, so that vocal communication was only established in one direction.

[Illustration: FIG. 15.]

‘The articulation produced from the instrument shown in fig. 15 was remarkably distinct, but its great defect consisted in the fact that it could not be used as a transmitting instrument, and thus two telephones were required at each station, one for transmitting and one for receiving spoken messages.

‘It was determined to vary the construction of the telephone, and I sought by changing the size and tension of the membrane, the diameter and thickness of the steel spring, the size and power of the magnet, and the coils of insulated wire around their poles, to discover empirically the exact effect of each element of the combination, and thus to deduce a more perfect form of apparatus. It was found that a marked increase in the loudness of the sounds resulted from shortening the length of the coils of wire, and by enlarging the iron diaphragm which was glued to the membrane. In the latter case, also, the distinctness of the articulation was improved. Finally, the membrane of goldbeaters’ skin was discarded entirely, and a simple iron plate was used instead, and at once intelligible articulation was obtained. The new form of instrument is that shown in fig. 16, and, as had been long anticipated, it was proved that the only use of the battery was to magnetise the iron core of the magnet, for the effects were equally audible when the battery was omitted and a rod of magnetised steel substituted for the iron core of the magnet.

‘It was my original intention, and it was always claimed by me, that the final form of telephone would be operated by permanent magnets in place of batteries, and numerous experiments had been carried on by Mr. Watson and myself privately for the purpose of producing this effect.

[Illustration: FIG. 16.]

‘At the time the instruments were first exhibited in public the results obtained with permanent magnets were not nearly so striking as when a voltaic battery was employed, wherefore we thought it best to exhibit only the latter form of instrument.

‘The interest excited by the first published accounts of the operation of the telephone led many persons to investigate the subject, and I doubt not that numbers of experimenters have independently discovered that permanent magnets might be employed instead of voltaic batteries. Indeed one gentleman, Professor Dolbear, of Tufts College, not only claims to have discovered the magneto-electric telephone, but I understand charges me with having obtained the idea from him through the medium of a mutual friend.

[Illustration: FIG. 17.]

‘A still more powerful form of apparatus was constructed by using a powerful compound horseshoe magnet in place of the straight rod which had been previously used (see fig. 17). Indeed the sounds produced by means of this instrument were of sufficient loudness to be faintly audible to a large audience, and in this condition the instrument was exhibited in the Essex Institute, in Salem, Massachusetts, on February 12, 1877, on which occasion a short speech shouted into a similar telephone in Boston, sixteen miles away, was heard by the audience in Salem. The tones of the speaker’s voice were distinctly audible to an audience of 600 people, but the articulation was only distinct at a distance of about 6 feet. On the same occasion, also, a report of the lecture was transmitted by word of mouth from Salem to Boston, and published in the papers the next morning.

[Illustration: FIG. 18.]

‘From the form of telephone shown in fig. 16 to the present form of the instrument (fig. 18) is but a step. It is in fact the arrangement of fig. 16 in a portable form, the magnet N S being placed inside the handle, and a more convenient form of mouthpiece provided.

‘And here I wish to express my indebtedness to several scientific friends in America for their co-operation and assistance. I would specially mention Professor Peirce and Professor Blake, of Brown University, Dr. Channing, Mr. Clarke, and Mr. Jones. It was always my belief that a certain ratio would be found between the several parts of a telephone, and that the size of the instrument was immaterial; but Professor Peirce was the first to demonstrate the extreme smallness of the magnets which might be employed. The convenient form of mouthpiece shown in fig. 17, now adopted by me, was invented solely by my friend Professor Peirce.’

[Illustration: FIG. 19.]

Another form of transmitting telephone exhibited in Philadelphia, intended for use with the receiving telephone (fig. 15), is represented by fig. 19.

A platinum wire attached to a stretched membrane completed a voltaic circuit by dipping into water. Upon speaking to the membrane, articulate sounds proceeded from the telephone in the distant room. The sounds produced by the telephone became louder when dilute sulphuric acid, or a saturated solution of salt, was substituted for the water. Audible effects were also produced by the vibration of plumbago in mercury, in a solution of bichromate of potash, in salt and water, in dilute sulphuric acid, and in pure water.

Mr. Bell goes on to say:

‘I have found also that a musical tone proceeds from a piece of plumbago or retort carbon when an intermittent current of electricity is passed through it, and I have observed the most curious audible effects produced by the passage of reversed intermittent currents through the human body. A rheotome was placed in circuit with the primary wires of an induction coil, and the fine wires were connected with two strips of brass. One of these strips was held closely against the ear, and a loud sound proceeded from it whenever the other slip was touched with the other hand. The strips of brass were next held one in each hand. The induced currents occasioned a muscular tremor in the fingers. Upon placing my forefinger to my ear a loud crackling noise was audible, seemingly proceeding from the finger itself. A friend who was present placed my finger to his ear, but heard nothing. I requested him to hold the strips himself. He was then distinctly conscious of a noise (which I was unable to perceive) proceeding from his finger. In this case a portion of the induced currents passed through the head of the observer when he placed his ear against his own finger; and it is possible that the sound was occasioned by a vibration of the surfaces of the ear and finger in contact.

‘When two persons receive a shock from a Ruhmkorff’s coil by clasping hands, each taking hold of one wire of the coil with the free hand, a sound proceeds from the clasped hands. The effect is not produced when the hands are moist. When either of the two touches the body of the other, a loud sound comes from the parts in contact. When the arm of one is placed against the arm of the other, the noise produced can be heard at a distance of several feet. In all these cases a slight shock is experienced so long as the contact is preserved. The introduction of a piece of paper between the parts in contact does not materially interfere with the production of the sounds, but the unpleasant effects of the shock are avoided.

‘When an intermittent current from a Ruhmkorff’s coil is passed through the arms, a musical note can be perceived when the ear is closely applied to the arm of the person experimented upon. The sound seems to proceed from the muscles of the fore-arm and from the biceps muscle. Mr. Elisha Gray[4] has also produced audible effects by the passage of electricity through the human body.

‘An extremely loud musical note is occasioned by the spark of a Ruhmkorff’s coil when the primary circuit is made and broken with sufficient rapidity; when two rheotomes of different pitch are caused simultaneously to open and close the primary circuit, a double tone proceeds from the spark.

‘A curious discovery, which may be of interest to you, has been made by Professor Blake. He constructed a telephone in which a rod of soft iron, about six feet in length, was used instead of a permanent magnet. A friend sang a continuous musical tone into the mouthpiece of a telephone, like that shown in fig. 17, which was connected with the soft iron instrument alluded to above. It was found that the loudness of the sound produced in this telephone varied with the direction in which the iron rod was held, and that the maximum effect was produced when the rod was in the position of the dipping-needle. This curious discovery of Professor Blake has been verified by myself.

‘When a telephone is placed in circuit with a telegraph line, the telephone is found seemingly to emit sounds on its own account. The most extraordinary noises are often produced, the causes of which are at present very obscure. One class of sounds is produced by the inductive influence of neighbouring wires and by leakage from them, the signals of the Morse alphabet passing over neighbouring wires being audible in the telephone, and another class can be traced to earth currents upon the wire, a curious modification of this sound revealing the presence of defective joints in the wire.

‘Professor Blake informs me that he has been able to use the railroad track for conversational purposes in place of a telegraph-wire, and he further states that when only one telephone was connected with the track the sounds of Morse operating were distinctly audible in the telephone, although the nearest telegraph-wires were at least forty feet distant; and Professor Peirce has observed the most curious sounds produced from a telephone in connection with a telegraph-wire during the aurora borealis.’

Mr. Bell went on to describe instances in which airs sung or played upon a musical instrument are transmitted by a telephone, when it is not known whence they come; but the strongest proof of the extraordinary sensibility of this instrument consists in its becoming possible by its means to transmit speech through bodies which might be supposed to be non-conductors. Thus communication with the earth through the human body can be made in spite of the intervention of shoes and stockings; and it may even be effected if, instead of standing on the ground, the person stands on a brick wall. Only hewn stone and wood are a sufficient hindrance to communication, and if the foot touches the adjoining ground, or even a blade of grass, it is enough to produce electric manifestations.

Mr. Bell says in conclusion:

‘The question will naturally arise, Through what length of wire can the telephone be used? In reply to this, I may say that the maximum amount of resistance through which the undulatory current will pass, and yet retain sufficient force to produce an audible sound at the distant end, has yet to be determined; no difficulty has, however, been experienced in laboratory experiments in conversing through a resistance of 60,000 ohms, which has been the maximum at my disposal. On one occasion, not having a rheostat at hand, I may mention having passed the current through the bodies of sixteen persons, who stood hand in hand. The longest length of real telegraph line through which I have attempted to converse has been about 250 miles. On this occasion no difficulty was experienced so long as parallel lines were not in operation. Sunday was chosen as the day on which it was probable other circuits would be at rest. Conversation was carried on between myself in New York, and Mr. Thomas A. Watson in Boston, until the opening of business upon the other wires. When this happened the vocal sounds were very much diminished, but still audible. It seemed, indeed, like talking through a storm. Conversation, though possible, could be carried on with difficulty, owing to the distracting nature of the interfering currents.

‘I am informed by my friend Mr. Preece that conversation has been successfully carried on through a submarine cable, sixty miles in length, extending from Dartmouth to the Island of Guernsey, by means of hand telephones.’

[Illustration: FIG. 20.]

Mr. Elisha Gray’s Share in the Invention of the Telephone.--We have seen that if Mr. Bell was the first to construct the speaking telephone in a practical form, Mr. Gray had at the same time conceived the idea of an instrument also capable of reproducing speech, and the description given of it in his _caveat_ was so precise that if it had been made from his design, it would have acted perfectly. This was, in fact, afterwards proved by him. In order that our readers may judge from their own knowledge of the share which should be ascribed to Mr. Elisha Gray in the invention of the telephone, we reproduce in fig. 20 the drawing which accompanied the _caveat_ in question.

The sender, as we see, is composed of a sort of tube, closed at its lower end by a membrane to which a platinum wire is fixed; this wire dips into a liquid of moderate conducting power, and an electrode made of platinum, in communication with a battery, is fixed at the bottom of the vessel containing the liquid. The receiver is composed of an electro-magnet, of which the armature is fixed to the centre of a membrane, stretched on a kind of resonator or ear-trumpet which is held to the ear, and the two instruments are united by the line wire as we see in the plate.

Under these conditions, the undulatory currents necessary for the reproduction of speech were obtained in a mode analogous to that pointed out by Mr. Bell in his specification, that is, by the variations of resistance in the liquid layer interposed between the platinum wires of the transmitter; and their action, exerted on an electro-magnet, of which the armature was fixed on the diaphragm of the resonator, was produced under more favourable conditions than in Mr. Bell’s specification (see fig. 13), since that gentleman regards this arrangement (represented in fig. 14) as an important improvement on his first conception.

The whole importance of the invention rests on the intervention of undulatory currents, which, as we have seen, are indispensable for the reproduction of speech, and it concerns us to know whether it was Mr. Bell or Mr. Gray who first declared their importance; for in both the specifications deposited on February 14, 1876, the use of undulatory currents was declared to be indispensable. Mr. Gray asserts that he had recognised their importance for the transmission of combined sounds as early as 1874; but Mr. Bell believes that the undulatory currents mentioned by Mr. Gray at that time were only currents analogous to those he had designated under the name of pulsatory currents, which we have represented in fig. 8. We have seen that since these currents only represent the abrupt elevations and depressions of intensity, they are unfit for the reproduction of articulate sounds, which, on the contrary, demand that the variations of intensity should result from successive efforts, in exact correspondence with all the inflections of the sonorous vibrations effected by the voice. Mr. Bell’s claim to priority on this question has been recognised by the American Patent Office, since he has been placed in possession of the patent. However this may be, Mr. Gray’s telephonic system was complete, and we see in it, as we have already said, the origin of the battery telephones, which have recently produced such important results. Let us now consider the relation which this system bears to Mr. Bell’s.

The Bell system, as we have seen, although making use of a battery in the first instance, only obtained the diminution and increase of electric force necessary for the articulation of words by means of induction currents produced by the movements of an armature of soft iron, currents of which the intensity was consequently due to the range and inflections of these movements. The battery only intervened in order to communicate magnetic force to the inducer. This use of induced currents in telephonic transmissions was already of great importance, since various experiments subsequently made have proved their superiority to voltaic currents for this

purpose. But experience soon convinced Mr. Bell that a powerful inductive apparatus worked by a battery was not only unnecessary for the action of this apparatus, but that a permanent magnet, very small and weak, would provide sufficient currents. This discovery, in which, as we have seen, Mr. Peirce had some share, was of great importance, since it became possible to reduce the size of the instrument considerably, so as to make it portable and adapted for sending and receiving; and it was shown that the telephone was the most sensitive of all instruments in revealing the action of currents. If, therefore, Mr. Bell was not the first to employ the successful mode of transmitting articulate words, it must be said that he sought, like Mr. Gray, to solve the problem by means of undulatory currents, and that he obtained these currents by the effect of induction, a system which, as soon as it was perfected, led to the important results with which we are all acquainted. If he had only given to the astonished world an instrument capable of reproducing speech telegraphically, his fame would be great; for this problem had hitherto been regarded as insoluble.

Mr. Gray's claims to the invention of the telephone are given in the following summary from a very interesting work, entitled 'Experimental Researches on Electro-harmonic Telegraphy and Telephony:'

'1. I was the first to discover the means of transmitting compound sounds and variable inflections through a closed circuit by means of two or more electric waves.

'2. I assert that I was the first to discover and utilise the mode of reproducing vibrations by the use of a magnet receiver constantly supplied with electric action.

'3. I also assert that I was the first to construct an instrument consisting of a magnet with a circular diaphragm of magnetic substance, supported by its edge at a little distance from the poles of a magnet, and capable of being applied to the transmission and reception of articulate sounds.'

It is a curious fact, worth recording here, that Mr. Yates, of Dublin, in 1865, when trying to improve Reiss's telephone, realised to a certain extent Mr. Gray's conception of the liquid transmitter; for he introduced into the platinum contacts of Mr. Reiss's instrument a drop of water which adapted it for the reproduction of articulate sounds. However, no notice was then taken of this result.

EXAMINATION INTO THE FUNDAMENTAL PRINCIPLES ON WHICH BELL'S TELEPHONE IS BASED.

Although the preceding account would suffice to make the principle of Bell's telephone intelligible to persons acquainted with electric science, this would not be the case with the majority of our readers, and we therefore think it necessary to enter into some details as to the source of the electric currents which are employed in telephonic transmissions. These details seem to us the more necessary, since many persons still believe that Bell's telephones are not electric, because they do not require a battery, and they are often confounded with string telephones, so that the difference of price between Bell's instruments and those hawked in the streets seems astonishing.

Without defining what is meant by an electric current, which would be too elementary, we may say that electric currents can be produced by different causes, and that, in addition to those which are due to batteries, strong currents are also produced by the force exerted by magnets on a conducting circuit properly arranged. Such currents are called induction currents, and are used in Bell's telephone. In order to understand how they are developed under these conditions, it will be enough to examine what takes place when the pole of a magnet is brought near to, and withdrawn from, a closed circuit. To do this, let us suppose a copper wire attached to a galvanometer in the form of a circle, and that one pole of a permanent magnet is directed towards the centre of the circle. Now observe what happens:

1. At the moment when the magnet approaches an electric current arises, causing the galvanometer to deviate to one side. This deviation will be great in proportion to the extent of the movement, and the tension of the current will be great in proportion to the abruptness of the movement. The current will however be only instantaneous.

2. At the moment when the magnet is withdrawn, a fresh current of the same nature will arise, but it will appear in an opposite direction from the former. It will be what is called a direct current, because it is in the same direction as the magnetic current of the magnet which produces it, while the other current is called _inverse_.

3. If, instead of advancing or withdrawing the magnet by means of a single movement, it is advanced in jerks, a succession of currents in the same direction is produced, of which the existence can be ascertained by the galvanometer when there is a sufficient interval between the movements, but when the intervals are very slight the currents are interfused; and since inverse effects take place when the magnet is moved in a contrary direction, the needle of the galvanometer follows the movements of the

magnet, and to a certain extent stereotypes them.

4. If, instead of reacting on a simple closed circuit, the magnet exerts its force on a considerable number of circumvolutions of this circuit, that is, on a bobbin of coiled wire, the effects will be considerably increased, and they will be still greater if there be a magnetic core within the bobbin, since the inducing action will then be more effectually exerted throughout the bobbin. As the magnetic core, when it is magnetised and demagnetised under the influence of its approach to or withdrawal from the inducing magnet, is subject to the reaction from all the fluctuations which occur in the movements of the magnet, the induced currents which ensue are perfectly defined.

5. If, instead of a movable magnet, we suppose it to be fixed in the centre of the coil, the induced currents of which we have spoken may then be determined by modifying its force. In order to do so, it is enough that an iron armature should react upon its poles. When this armature is brought close to one of the poles, or to both at once, it acquires force, and produces an inverse current, that is, a current in the direction which would have corresponded to an approach of the magnet to the closed circuit. On its withdrawal the inverse effect is produced; but in both cases the induced currents correspond with the extent and direction of the movements accomplished by the armature, and consequently they may reproduce its movements by their effects. If this armature is an iron plate, which vibrates under the influence of any sound in this disposition of the electro-magnetic system, the alternate movements of the plate will be transformed into the induced currents, and these will be stronger or weaker, more or less definite, according to the range and complexity of the vibrations: they will, however, be undulatory, since they will always result from successive and continuous movements, and will consequently be in the conditions which, as we have seen, are required for the transmission of speech.

As for the action produced upon the receiver, that is, on the instrument for reproducing speech, it is somewhat complex, and we shall have occasion to speak of it presently; but we can get a general impression of it, if we consider that the effects produced by the induced currents of variable intensity, which traverse the coil of the electro-magnetic system, must determine, by the magnetisations and demagnetisations which ensue, the vibrations of the armature disk; these vibrations, more or less amplified and defined, exactly represent those of the disk before which the speaker stands, and can only be obtained from them. The effects are, however, in reality more complex, although they are produced under analogous conditions, and we shall have more to say about them when we come to speak of the experiments made with the telephone. It must meanwhile be observed that, for the reproduction of speech, it is not necessary that the magnetic core should be of soft iron, since the vibratory effects may follow from differential as well as from direct magnetisation.

ORDINARY ARRANGEMENT OF THE BELL TELEPHONE.

The arrangement most generally adopted for the telephone is the one represented in fig. 21. It consists of a kind of circular wooden box, fitted to the extremity of a handle M, which is also of wood, and contains the magnetic bar N S. This bar is fixed by means of a screw _t_, and is so arranged as to be moved forward and backward by tightening or loosening the screw, a condition necessary in order to regulate the instrument. At the free extremity of the bar the magnetic coil B is fixed; this must, according to MM. Pollard and Garnier, be made of wire No. 42, so as to present a considerable number of spirals. The ends of this coil generally terminate at the lower end of the handle in two copper rods _f_, _f_, which traverse its length, and are fastened to two binding-screws l, l′, where the line wires C, C are fixed. In the instruments made by M. Bréguet there are, however, no binding-screws, but a little twist, made of two flexible wires covered with gutta-percha and silk, is fastened to the two rods. A wooden cap is screwed to the end of the handle, and the twist passes through a hole made in this cap, so that there is no inconvenience in working the instrument. By laying hold of the ends of the wire twist with pliers it is possible to join them to the circuit. This instrument is represented in fig. 22.

[Illustration: FIG. 21.]

By another arrangement, the wires of the coil end immediately in the binding-screws which are placed below the wooden box, but this arrangement is inconvenient.

Above the pole of the magnetic bar is placed the iron vibrating plate L L, which is coated either with black or yellow varnish, with tin or blue oxide, but which must always be very thin. This plate is in the form of a disk, and by its rim, resting on a caoutchouc ring, it is firmly fixed to the circular edges of the wooden box, which is for this purpose made in two pieces. These pieces are adjusted to each other, either by screws or by spirals cut in half the thickness of the wood. This disk ought to be as near as possible to the polar end of the magnet, yet not so near as to produce contact between the two by the vibrations of the voice. Finally, the mouthpiece R

R′ (fig. 21), which is in form of a wide funnel, terminates the upper part of the box, and should be so arranged as to leave a certain space between the disk and the edges of the hole V, which is open in its centre. The size of the box should be so calculated as to permit of its acting as a sounding-box, without however provoking echoes and a confusion of sounds.

[Illustration: FIG. 22.]

When the instrument is properly made, it will produce very marked effects; and M. Pollard, one of the first Frenchmen to take up the study of telephones, has written as follows on the subject:

‘The instrument which I have prepared gives results which are truly astonishing. In the first place, when considering the resistance, the introduction into the circuit of five or six persons does not sensibly diminish the intensity of sounds. On putting an instrument to each ear, the sensation is precisely the same as if the correspondent were speaking some yards behind. The intensity, the clearness, the purity of tone are irreproachable.

‘I can speak to my colleague in quite an undertone, scarcely breathing as I may say, and persons placed within two yards of me will be unable to catch a single word of our conversation.

‘On the part of the receiver, if anyone raises his voice to call me, I hear the call in all parts of my office, at least when silence prevails there; at any rate, when I am seated at my table with the instrument some yards off, I can always hear the call. In order to increase the intensity of sound, I fitted the mouthpiece with a copper horn of conical shape, and under these conditions words spoken in my bureau two or three yards from the mouthpiece can be heard at the other end of the line; from my station, a little more than a yard from the tube, I can hear and speak to my colleague without effort.’

In using the ordinary Bell telephone, it is necessary to speak distinctly before the mouthpiece of the telephone which is handled, while the listener placed at the corresponding station keeps the mouthpiece of the receiver to his ear. These two instruments form a closed circuit with the two wires which connect them, but one is enough to make the transmission perfect, if care is taken to place both instruments in connection with the earth, which thus takes the place of the second wire. M. Bourbouze asserts that the intensity of sound in the telephone is much increased by employing this expedient, but we believe that this increase depends upon the conditions of the circuit, although he asserts that the fact can be proved in a circuit not exceeding eighty yards.

For practical purposes it is necessary to have two telephones at each station, so as to hold one to the ear while speaking through the other, as in fig. 23. It is also much more easy to hear with a telephone applied to each ear, in which case they are held as in fig. 24. In order not to fatigue the arms, an arrangement has been made by which they are held before the ears by a strap and spring which goes round the head.

[Illustration: FIG. 23.]

The sending power of the telephone varies with different voices. Mr. Preece asserts that shouting has no effect, and that, in order to obtain a favourable result, the intonation must be clear, the articulation distinct, and the sounds emitted must resemble musical sounds as much as possible.

Mr. Wilmot, one of the electricians employed by the Post Office, says that he has been able to make himself heard on circuits through which no other voices were audible. The vowel sounds are most readily transmitted, and among other letters _e_, _g_, _j_, _k_, and _q_ are always repeated more imperfectly. The ear requires practice, and the faculty of hearing varies in a surprising degree in different people. Singing is very distinctly heard, as well as wind instruments, especially the cornet-à-piston, which, when played in London, was heard by thousands of people in the Corn Exchange at Basingstoke.

[Illustration: FIG. 24.]

According to Mr. Rollo Russell, it is not necessary to isolate the circuit of a telephone when the distance is relatively slight; thus, with a circuit of about 430 yards, it is possible to use a simple copper wire, laid on the grass, without destroying the telephonic transmission from a small musical box, as long as the two wires do not touch each other. Transmission took place, even when the circuit was buried in moist earth for a length of thirty-five yards, or immersed in a well for a length of forty-eight yards. The words transmitted under such conditions did not differ from those transmitted by an isolated circuit.

The telephone may be heard at the same moment by several listeners, either by connecting the wires which unite the telephones in correspondence (near the receiving telephone) with branch wires of other telephones, which may be done up to the number of five

or six, in short circuits; or by means of a little sounding-box closed by two thin membranes, one of which is fixed on the vibrating disk. When a certain number of acoustic tubes are connected with the membrane, Mr. M'Kendrick asserts that several people can hear distinctly.

Telephones may also transmit speech to different stations simultaneously, by inserting them on the same circuit, and experiments made at New York showed that five instruments placed in different parts of the same telegraphic line could be made to speak in this way. In the telephonic experiments made on the canal lines in the department of the Yonne, it was ascertained that on a wire seven miles and a half in length, on which several telephones were placed at varying distances, three or four persons were able to converse with each other through the telephones, and each could hear what the other was saying. The questions and answers could be understood, even in crossing. It was also possible, by placing a telephone on a second wire, a little over five miles in length, and half a yard distant from the other, to hear the conversation exchanged on the first wire by following it to a distance not exceeding a mile and a quarter. Even the different voices of the two speakers could be distinguished.

Since the telephone made its appearance in Europe, several inventors have asserted that they are able to make a telephone speak so as to be audible in all parts of a large hall. It has been shown that this was accomplished by Mr. Bell, and in this respect we do not see that those who have attempted to improve the telephone have attained results of greater importance. It is certain that the ordinary telephone can emit musical sounds which become perfectly audible in a tolerably large room, while the instrument is still attached to the wall. We should also remember the results obtained by MM. Pollard and Garnier in the experiments made at Cherbourg to connect the mole with the _Préfecture Maritime_.

The mole at Cherbourg is, as we know, a kind of artificial island thrown up before the town in order to make an anchorage. The forts which have been constructed on the mole are connected by submarine cables with the military port and with the _Préfecture Maritime_. On one occasion, after making experiments in the Préfet's study on one of the cables applied to a telephone, several persons were talking together in the room, and were much surprised to hear the bugle sound the retreat, the sound appearing to come from one part of the room. It was found, on examination, that the telephone hung to the wall was occupied with this performance. On enquiry, it appeared that one of the manipulators on the mole station had amused himself by sounding the bugle before the telephone on that station. The mole is more than three miles from Cherbourg, and the _Préfecture Maritime_ is in the centre of the town. Yet these telephones had been roughly made in the dockyard workshops; and we have here another proof of the small amount of accuracy required for the successful working of these instruments.

[Illustration: FIG. 25.]

Telephones of various construction on the Bell model are to be seen at M. C. Roosevelt's, Mr. Bell's agent in Paris, 1, Rue de la Bourse. They are, for the most part, constructed by M. Bréguet, and the model in the greatest request, exclusive of the one we have described, is the great square model, with a horseshoe magnet enclosed in a flat box, and a horn on its upper side, which serves as a mouthpiece. This system is represented in fig. 25, and it has been neatly constructed at Boston under the best conditions. In this new model, made by Mr. Gower, the magnet is composed of several plates terminated by magnetic cores of iron, to which the coils are fixed, and the whole is covered with a thick layer of paraffin. The sounds thus reproduced are much stronger and more distinct. Mr. Gower, who is now Mr. Roosevelt's partner, has made considerable improvements in the different forms of Mr. Bell's instrument. There is one model in the form of a snuff-box, in which the magnet is twisted into a spiral, so as to maintain its length in a circular form. The pole, which is in the centre of the spiral, is furnished with an iron core, to which the induction coil is fastened, and the cover of the snuff-box supports the vibrating disk as well as the mouthpiece: this model is represented in fig. 26. In another model, called the mirror telephone, the preceding arrangement is fitted on to a handle like the glass of a portable mirror, and there is a mouthpiece on one of the lateral faces, so that the speaker uses the instrument as if he were speaking before a chimney screen.

[Illustration: FIG. 26.]

Mr. Bailey has different models of telephones worked by a battery or by the Edison carbon of which we shall speak presently, and these, as well as the telephones by Messrs. Gray and Phelps, are more successful in conveying sound on a long line of wire.

DIFFERENT ARRANGEMENTS OF TELEPHONES.

The prodigious results attained with the Bell telephones, which were at first discredited by many scientific men, necessarily provoked, as soon as their authenticity was proved, innumerable researches on the part of inventors, and even of those who were

originally the most incredulous. A host of improvements and modifications have consequently been suggested, which are evidently not without interest, and must now be considered by us.

BATTERY TELEPHONES.

The Edison Telephone.--One of the earliest and most interesting improvements made in the Bell telephone is that introduced by Mr. Edison in the early part of the year 1876. This system is indeed more complicated than the one we have just considered, since it requires a battery, and the sending instrument differs from the receiving instrument; but it is less apt to be affected by external causes, and transmits sound to a greater distance.

The Edison telephone, like Mr. Gray's, which we have already had occasion to mention, is based upon the action of undulatory currents, determined by the variations in the resistance of a conductor of moderate conducting power, which is inserted in the circuit, and the vibrations of a diaphragm before which the speaker stands react upon it. Only, instead of employing a liquid conductor, which is practically useless, Mr. Edison has attempted to use semi-conducting solid bodies. Those which were most suitable from this point of view were graphite and carbon, especially the carbon extracted from compressed lamp-black. When these substances are introduced into a circuit between two conducting plates, one of which is moveable, they are capable of modifying the resistance of the circuit almost in the same proportion as the pressure exerted upon them by the moveable plate,[5] and it was seen that, in order to obtain the undulatory currents necessary for the production of articulate sounds, it was enough to introduce a disk of plumbago or of lamp-black between the vibrating plate of a telephone and a platinum plate placed in connection with the battery. When the telephone disk is placed in circuit, its vibrations before the disk of carbon produce a series of increasing and decreasing pressures, thus causing corresponding effects in the intensity of the transmitted current, and these effects react in an analogous manner on the undulatory currents determined by induction in the Bell system. In order to obtain good results, however, several accessory arrangements were necessary, and we represent in fig. 27 one of the arrangements made in this part of Mr. Edison's telephonic system.

[Illustration: FIG. 27.]

In this figure a section of the instrument is given, and its form greatly resembles that of Bell. L L is the vibrating disk; O′ O, the mouthpiece; M, the opening to the mouthpiece; N N N, the case for the instrument, which is, like the mouthpiece, made of ebonite, and below the disk it presents a rather large cavity, and a tubular hole which is scooped in the handle. In its upper part this tube terminates in a cylindrical rim, furnished with a worm on which is screwed a little rod with a ridge on its inner side, and the rheostatic system is placed within this tube. The system consists, first, of a piston E, fitted to the end of a long screw E F, and the turning of the button will move the piston up or down within a certain limit. Above this piston there is fitted a very thin platinum plate A, connected by a flexible chain and a wire with a binding-screw P′. Another plate B, exactly similar, is connected with the binding-screw P, and the carbon disk C is placed between these two plates. This disk is composed of compressed lamp-black and petroleum, and its resistance is one _ohm_, or 110 yards, of telegraphic wire. Finally, an ebonite disk is fastened to the upper platinum plate, and an elastic pad, composed of a piece of caoutchouc tube G, and of a cork disk H, is interposed between the vibrating plate L L and the disk B, in order that the vibrations of the plate may not be checked by the rigid obstacle formed by the whole rheostatic system. When these different parts are in position, the instrument is regulated by the screw F, and this is easily done by screwing or unscrewing it until the receiving telephone gives out its maximum of sound.

[Illustration: FIG. 28.]

In another model, represented in fig. 28, which has produced the best results in the distinctness with which sounds are transmitted, the vibrating plate L L is supported on the disks of the secondary carbon conductor C by means of a little iron cylinder A, instead of the caoutchouc pad, and the pressure is regulated by a screw placed below _e_. The mouthpiece E of the instrument is more prominent, and its opening is larger. Finally, the instrument, which is cased in nickel silver, is without a handle. The rigid disk _b_, resting on the first platinum plate _p_, is of aluminium instead of ebonite.

[Illustration: FIG. 29.]

The receiving telephone somewhat resembles that of Mr. Bell, yet it presents some differences which can be understood from the examination of fig. 29. The magnet N S is horseshoe in form, and the magnetising coil E only covers one of the poles, N: this pole is precisely in the centre of the vibrating plate L L, while the second pole is near the edge of this plate. The size of the plate itself is considerably reduced: its superficies is about the same as that of a five-franc piece, and it is enclosed in a kind of circular groove,

which keeps it in a definite position. In consequence of this arrangement the handle of the instrument is of solid wood, and the vacant space for the electro-magnetic system is somewhat larger than in the Bell model; but an arrangement is made for subduing the echo, and there is a kind of sounding-box to magnify the sound. It is evident that the relation which the electro-magnetic system bears to the vibrating disk must increase the sensitiveness of the instrument; for as the pole S is in close contact with the disk L L, the latter is polarised, and becomes more susceptible to the magnetic influence of the second pole N, which is separated from it by an interval not exceeding the thickness of a sheet of coarse paper. In Mr. Edison's two instruments, the receiver and sender, the upper part C C, corresponding to the vibrating disk, instead of being fixed by screws to the handle, is screwed on to the handle itself, which makes it much more easy to dismount the instrument.

Mr. Edison has varied the form of his instruments in many ways, and their cases have of late been made of metal with a funnel-shaped mouthpiece of ebonite.

When Mr. Edison had ascertained, as indeed Mr. Elisha Gray had done before him, that induced currents are more favourable to telephonic transmissions than voltaic currents, he transformed the currents from the battery which passed through his sender into induced currents by making them pass through the primary circuit of a carefully insulated induction coil; the line wire was then put into communication with the secondary wire of the coil. We shall afterwards describe some experiments which show the advantages of this combination: for the present we can only point out the fact, for it is now an integral quality of almost all the systems of battery telephones.

Edison's Chemical Telephone.--The curious and really useful effects produced by Mr. Edison with his _electro-motograph_ prompted, about the beginning of the year 1877, his idea of applying the principle of this instrument to the telephone for the reproduction of transmitted sounds; and he obtained such interesting results that the author of an article on telephones, published in the 'Telegraphic Journal,' August 15, 1877, put forward this invention as one of the finest of the nineteenth century. It certainly appears to have given birth to the phonograph, which has lately become famous, and has so much astonished men of science.

To understand the principle of this telephone, we must give some account of Mr. Edison's electro-motograph, discovered in 1872. This instrument is based upon the principle that if a sheet of paper, prepared with a solution of hydrate of potash, is fastened on a metallic plate which is united to the positive pole of a battery, and if a point of lead or platinum connected with the negative pole is moved about the paper, the friction which this point encounters ceases after the passage of the current, and it is then able to slide as if upon a mirror until the current is interrupted. Now, as this reaction may be effected instantaneously under the influence of extremely weak currents, the mechanical effects produced by these alternations of arrest and motion may, by a suitable arrangement of the instrument, determine vibrations in correspondence with the interruptions of current produced by the transmitter.

In this system the telephonic receiver consists of a resonator and a drum mounted on an axis and turned by a winch. A paper band, wound upon a reel, passes over the drum, of which the surface is rough, and a point tipped with platinum, and fitted to the end of a spring which is fixed in the centre of the resonator, presses strongly on the paper. The current from the battery, first directed on the spring, passes by the platinum point through the chemical paper, and returns by the drum to the battery. On turning the winch, the paper moves forward, and the normal friction which is produced between the paper and the platinum point pushes the point forward, while producing by means of the spring a tension on one side of the resonator; but since the friction ceases at each passage of the current through the paper, the spring is no longer drawn out, and the resonator returns to its normal position. Since this double effect is produced by each vibration made in the sender, a series of vibrations takes place in the resonator, repeating those of the sender, and consequently the musical sounds which affected the sender are reproduced to a certain extent. According to the American journals, the results produced by this instrument are astonishing: the weakest currents, which would have no effect on an electro-magnet, become perfectly efficacious in this way. The instrument can even reproduce with great intensity the highest notes of the human voice, notes which can hardly be distinguished by the use of electro-magnets.

The sender nearly resembles the one we have previously described, except that, when it is used for musical sounds, a platinum point is employed instead of the disk of carbon, and it ought not to be in constant contact with the vibrating plate. According to the 'Telegraphic Journal,' it consists simply of a long tube, two inches in diameter, having one end covered with a diaphragm formed of a thin sheet of copper, and kept in its place by an elastic ring. A small platinum disk is riveted to the centre of the copper diaphragm, and a point of the same metal, fitted with a firm support, is adjusted before the disk. When the singer stands before the diaphragm, its vibration causes it to touch the platinum point, and produces the number of breaks in the current which corresponds to the vibration of the notes uttered.

The experiments lately made in America, in order to decide on the merits of various telephonic systems, show that Mr. Edison's telephone gives the best results. The 'Telegraphic Journal,' May 1, 1878, states that on April 2 Mr. Edison's carbon telephone was tested between New York and Philadelphia on one of the numerous lines of the West Union. The length of the line was 106 miles, and ran parallel to other wires almost throughout its length. The effects of induction caused by telegraphic transmissions through the adjacent wires were enough to make speech inaudible through the other telephones, but they had no influence on Edison's telephone, which was worked with a battery of two cells and a small induction coil, and Messrs. Batchelor, Phelps, and Edison were able to converse with ease. Mr. Phelps' magnetic telephone, which is considered to be the most powerful of its kind, did not afford such good results.

In the experiments made between the Paris Exhibition building and Versailles, the jury commission was able to ascertain that the results were equally favourable.

Telephones by Colonel Navez.--Colonel Navez of the Belgian Artillery, inventor of the well-known balistic chronograph, has endeavoured to improve the Edison telephone by employing several disks of carbon instead of one. He considers that the variations of electric resistance produced by carbon disks under the influence of unequal pressure depend chiefly on their surface of contact, and he consequently believes that the more these surfaces are multiplied, the greater the differences in question will be, just as it happens when light is polarised through ice. He adds that these disks act well by their surfaces of contact, since, if they are separated by copper disks, the speech reproduced ceases to be articulate.[6]

I am not surprised to learn that Colonel Navez has found a limit to the number of carbon disks, for the reproduction of speech in this system is due both to the greatness of the differences of resistance in the circuit, and to the intensity of the transmitted current. If therefore the instrument's sensitiveness to articulate sounds is increased by increasing the number of imperfect contacts in the circuit, the intensity of the transmitted sounds is diminished, and thus sounds lose their power. There is consequently a limit to be observed in the number of carbon disks placed upon each other; and it depends on the nature of the imperfect contacts which are employed, and on the tension of the electric generator.

In order to stop the unpleasant musical vibrations which accompany telephonic transmissions, Colonel Navez employs for the vibrating plate of the sender a silver-plated copper disk, and for the vibrating plate of the receiver an iron disk lined with brass and soldered together. He also employs caoutchouc tubes with mouthpieces and ear-tubes for the transmission and reception of sound, and these instruments are placed level on a table. For this purpose the magnetised bar of the receiving telephone is replaced by two horizontal magnets, acting through a pole of the same nature on a little iron core which carries the coil, and which is placed vertically between the two magnets. He necessarily makes use of a small Ruhmkorff coil to transform the electricity of the battery into induced electricity.

[Illustration: FIG. 30.]

[Illustration: FIG. 31.]

Figs. 30 and 31 represent the two parts of this telephonic system. The carbon battery is in C (fig. 30), the vibrating disk in L L, and the mouthpiece E, fitted to a caoutchouc tube T E, corresponds at the lower end to the vibrating disk. The carbon battery is placed in metallic contact with the circuit by a platinum rod E C, and the vibrating disk also communicates with the circuit through a binding-screw. In the receiving telephone (fig. 31) the upper part is arranged much as in the ordinary telephones, except that, instead of a mouthpiece, the instrument is fitted with an ear-tube T O. The two horseshoe magnets, A, A, which communicate a uniform polarity to the iron core N, support the induction coil B. The two terminals of this receiver are connected with the supplementary wire of the induction coil, and the two terminals of the sender are connected with the two ends of the primary of this coil, and with the battery which is inserted in the circuit near this instrument.

The Pollard and Garnier Telephones.--The battery telephone made by MM. Pollard and Garnier differs from the foregoing in this particular: it simply employs two points of graphite, mounted in metallic porte-crayons, and these points are directly applied against the vibrating plate with a pressure which must be regulated. Fig. 32 represents the arrangement adopted, which, however, may be infinitely varied.

L L is the vibrating tin plate, above which is the mouthpiece E, and P, P′ are the two graphite points with their porte-crayons. There is a screw on the lower part of the porte-crayons which is fixed in a hole pierced in a metallic plate C C, and by this means the pressure of the pencils against the disk L L can be regulated. The metallic plate C C is made in two pieces, placed side by side, but

insulated from each other, so that they may be placed in communication with a cylindrical commutator, and by its means the circuit can be arranged in different ways. Since the commutator consists of five sheets, the transition from one combination to another is instantaneous, and these combinations are as follows:

1. The current enters by the pencil P, passes into the plate, and so to line.

2. The current enters by the pencil P′, passes into the plate, and so to line.

3. The current comes simultaneously by the two pencils P and P′, goes into the plate, and thence to line.

4. The current comes by the pencil P, goes thence to the plate, then into the pencil P′, and so to line.

[Illustration: FIG. 32.]

By this means there are two elements of combination, which may be employed separately, or by coupling them for tension or quantity.

When the pencils are properly regulated and give a regular transmission of equal intensity, the effects produced in the transition from one combination to another may be easily studied, and it has been ascertained: first, that in a short circuit there is no appreciable change, whatever be the combination employed; secondly, that when the circuit is long, or of great resistance, the tension arrangement is the best, and this in proportion to the length of the line.

This telephonic system, like the two preceding ones, requires an inducing machine to transform voltaic into induced currents: we shall presently speak of this important accessory of these instruments.

Besides this arrangement, MM. Pollard and Garnier have employed the one we have represented in fig. 5, which has given better results. We shall see presently that it can be used as the receiving organ of sounds. In each case the two carbons must be placed in contact, and subjected to a certain initial pressure, which should be regulated by the screw fitted to the support of the lower carbon.

As for the receiving telephone, the arrangement adopted by MM. Pollard and Garnier is the same as Bell’s, except that they employ tin plates and helices of greater resistance. This resistance ranges in fact from 100 to 125 miles. ‘We have always held,’ these gentlemen say, ‘that whatever may be the resistance of the outer circuit, there is an advantage in increasing the number of spirals, even when using wire No. 42, which is the one we prefer.’

[Illustration: FIG. 33.]

M. Hellesen’s Reaction Telephone.--M. Hellesen believed that the vibrations produced by the voice on the carbon of a telephonic sender would be magnified if the moveable part of the rheotome were subjected to an electro-magnetic action resulting from the vibrations themselves, and he has contrived a sender, which is based on the principle shown in fig. 33, and which has the merit of forming in itself the inducing apparatus intended to transform the voltaic currents employed. This instrument is composed of a vertical iron tube, supported on a magnetic bar N S, and surrounded by a magnetising coil B B, above which is fixed an inducing helix of fine wire I I, communicating with the circuit. Within the tube there is a lead pencil C, held by a porte-crayon which can be raised or lowered by means of a screw V fixed below the magnetic bar. Finally, above this pencil, there is an iron vibrating plate L L, with a platinum point in communication with the battery in its centre; the local circuit communicates with the pencil by means of the magnetising helix B, and for this purpose one end is soldered to the iron tube.

From this arrangement it follows that the vibrations of the plate L L, at the moment when it comes nearest to the pencil, tend to become greater in consequence of the attractive force exerted on the plate, and as the pressure of the lead pencil is increased, it increases the differences of resistance which result from it, and consequently causes greater variations in the intensity of the transmitted currents.

Reaction Telephone of Messrs. Thomson and Houston.--The telephonic arrangement we have described has lately been adopted by Mr. Elihu Thomson and Mr. Edwin J. Houston, who, on June 21, 1878, two months after M. Hellesen explained his system to me,[7] published an article in ‘The English Mechanic and World of Science’ about an instrument very similar to that of M. Hellesen.

In their instrument, the current, which passes through a body of moderately conducting capacity, acts on an electro-magnet provided with an induction coil, and this electro-magnet reacts on the diaphragm, in order to increase the range of its vibrations, and to create at the same moment two electric actions in the same direction: the only difference lies in the arrangement of the contact of this indifferent conductor with the vibrating plate. Instead of a simple contact effected by pressure between this plate and a carbon pencil, a fragment of the same substance with a sharpened point is fixed on the vibrating plate, and it dips into a drop of mercury which has been poured into the receptacle made for it at the upper end of the electro-magnet. In other respects, the arrangement of the instrument is that of an ordinary telephone, and the iron rod of the electro-magnet represents the magnetised bar of the Bell telephone. The inventors assert that this instrument can be used both as a sender and receiver, and it is in the following manner that it is worked in each case.

When the instrument is transmitting, the morsel of carbon dips more or less into the mercury, and consequently differences are produced in the surfaces of contact, according to the range of vibrations made by the plate; the current varies in intensity in proportion to this range, and induced currents in the induction coil result from these variations; the induced currents react on the receiving telephone, as in Bell's instrument, and are further strengthened by those which are produced electrically by the movement of the diaphragm before the induction coil, and the iron of the electro-magnet.

When the instrument is used as a receiver, the usual effects are displayed, for since the iron of the electro-magnet is magnetised by the current, its conditions are precisely those of the ordinary Bell telephone, and the induced currents reach it in the same manner, only with greater intensity. Messrs. Thomson and Houston assert that their system has produced excellent results, and that by it the sound of the voice is much less altered than in other telephones.

Telephones with batteries and liquid senders.--We have seen that in 1867 Mr. Gray conceived the idea of a telephonic system based on the differences of resistance effected in a circuit completed by a liquid, when the layer of liquid interposed between the electrodes varies in thickness under the influence of the vibrations of the telephonic plate which is in communication with one of these electrodes. This system has since been the subject of study by several inventors, among others by MM. Richemond and Salet; and I give some of the accounts which have been published respecting their researches.

Another telephone for the reproduction of articulate sounds, which M. Richemond terms the _electro-hydro telephone_, has been recently patented in the United States. It resembles that of Mr. Edison in some respects, but instead of making use of carbon disks to modify the resistance of the circuit, water is employed, and this water is placed in communication with the circuit and battery by means of two platinum points, one of which is fixed on the metallic diaphragm which vibrates under the influence of the voice. As the vibrations of the diaphragm transport the point which is attached to it to different parts of the interpolar layer of liquid, they diminish or increase the electric resistance of this layer, and cause corresponding variations in the intensity of the current traversing the circuit. The receiving telephone is of the usual kind. (See 'Telegraphic Journal,' September 15, 1877.)

M. Salet writes: 'I thought it would be interesting to construct a telephone in which there should be absolute solidarity in the movements of the two membranes, and for this purpose I have availed myself of the great resistance of liquids. Mr. Bell had already obtained some results by attaching to the vibrating membrane a platinum wire communicating with a battery, and dipping more or less into a metallic vessel, itself connected by the line with the receiving telephone and containing some acidulated water. I have substituted for the platinum wire a small aluminium lever supporting a disk of platinum, and at a very slight distance from it there is a second disk in connection with the line. The vibrations of the membrane, tripled or quadrupled in their range, are not altered in form, thanks to the small size and light weight of the lever: they cause variations in the thickness of the liquid layer traversed by the current, and consequently in its intensity, and these variations cause corresponding differences in the attractive force of the receiving electro-magnet. Under its influence the receiving membrane executes movements which are identical with those of the sending membrane. The sound transmitted is very distinct, and its _timbre_ is perfectly maintained, a result which might have been anticipated. The consonants, however, are not so clearly pronounced as those transmitted by Mr. Bell's instrument. This inconvenience is most apparent when the lever is heavy, and might easily be obviated. The electrolysis also produces a continual murmur, but this does not interfere with the distinctness of the sound.

'Since on this system the voice is not required to _produce_, but only to _direct_ the electric current generated by a battery, the intensity of the sound received might in theory be increased at pleasure. I have in fact been able to make the receiver emit very powerful sounds, and I think that this advantage greatly counterbalances the necessity of employing a battery, and a somewhat delicate sending instrument. Unfortunately it can only be used for moderate distances. Assuming that any displacement of the transmitting membrane increases the resistance to a degree equivalent to five or six hundred yards of wire: if the line is five

hundred yards long, the intensity of the current will be reduced by one half, and the receiving membrane will take up a fresh position, considerably differing from the first; but if the line is three hundred miles in length, the intensity of the current will only be modified by a thousandth part. An immense battery must therefore be employed in order that this variation may be translated by a sensible change in the position of the receiving membrane.' (See 'Comptes Rendus de l'Académie des Sciences,' February 18, 1878.)

M. J. Luvini, in an article inserted in 'Les Mondes,' March 7, 1878, has suggested a system of rheotome by means of a current, for battery telephones, which, although complicated, possibly offers some advantages, since it produces currents alternately reversed. In this system, the vibrating disk of the sender, which should be in a vertical position, reacts on a moveable horizontal wire, turned back at a right angle, and supporting on each of its branches two platinum points which dip into two bulbs, filled with a liquid of moderate conducting capacity. The two branches of this wire, insulated from each other, are placed in communication with the two poles of the battery, and the four cups into which the platinum wire dips communicate inversely with the line and the earth by means of platinum wires immoveably fixed in the cups. It follows from this arrangement, that when the distances are duly regulated between the fixed and moveable wires, two equal currents will be opposed to each other across the line circuit when the diaphragm is motionless; but as soon as it vibrates, the respective distances of the wires will vary, and it follows from this that there will be a differential current, of which the intensity will correspond with the extent of the displacement of the system, or with the range of vibrations, and the direction will vary with the movements above or below the line of the nodes of vibration. In this way the advantage of the induced currents is obtained.

Telephones with a battery and voltaic arcs.--In order to obtain variations of resistance of still greater sensitiveness than is the case with liquids or pulverised substances, the idea has been suggested of employing conductors of heated gas, and several arrangements of battery telephones have been made in which the circuit was completed by a stratum of air, separating the vibrating disk from a platinum point, which serves to excite an electric discharge of high tension. Under these conditions, the stratum of air becomes the conductor, and the intensity of the current which traverses it corresponds to its thickness. This problem has been solved, either by means of voltaic currents of high tension, or by a Ruhmkorff coil.

The former system was arranged by M. Trouvé, and he writes as follows on the subject in the journal 'La Nature' of April 6, 1878: 'A metallic vibrating membrane forms one of the poles of a high tension battery; the other pole is fastened before the disk by a micrometer screw which can be adjusted so as to vary the distance from the disk according to the tension of the battery, but without ever coming in contact with it. The distance must not in any case exceed that to which the discharge of the battery can extend. Under these conditions, the membrane which vibrates under the influence of the waves of sound has the effect of constantly modifying the distance between the two poles, and thus of continually varying the intensity of the current: consequently the receiving instrument (a Bell telephone, or telephone with an electro-magnet) is subjected to magnetic variations, corresponding to the variations of the current which affect it, and this has the effect of making the receiving instrument vibrate at the same moment. This kind of telephonic instrument relies, therefore, on the possibility of varying within wide limits the resistance of the outer circuit of a high-tension battery, in which the poles are not in contact. In order to vary the conditions of this resistance, it is also possible to interpose some vapour or other medium, such as air, or gas of greater or less rarity.'

M. Trouvé thinks that he was successful with his battery of small disks, moistened with sulphate of copper and sulphate of zinc, arranging these elements, to the number of five or six hundred, in glass tubes of small diameter. It is well known that it is unnecessary for the elements to be of large size in order to obtain tension currents.

M. de Lalagade has suggested an analogous mode by employing for the formation of the arc a current of which the tension is increased by inserting a strong electro-magnet into the circuit. This electro-magnet acts on a Hughes magnet in order to produce induction currents capable of making the receiving instrument act. M. de Lalagade says that a Bunsen battery, or one of six cells with bichromate of potash, will be enough to produce a continuous voltaic arc between the vibrating plate of a telephone and a platinum point which is sufficiently remote to avoid contact. It is necessary, however, to begin with a contact, in order to produce the formation of this arc. In M. de Lalagade's system, the vibrating plate should have in its centre a small platinum plate, in order to obviate the oxidising effects of the spark. The inventor asserts that sounds transmitted in this way, and reproduced in a telephone of which the electro-magnetic system is set upon a sounding-box, will have greater intensity than the sounds transmitted by an ordinary telephone, and the speaker will appear to be close to the ear.

Mercury Telephones.--These systems are based on the physical principle discovered by M. Lippmann, that if a layer of acidulated water is placed above mercury, and connected with it by an electrode and wire, every mechanical action which exerts

pressure on the surface of the mercury, and alters the form of its meniscus, will cause an electric reaction, capable of producing a current with a force which corresponds to the mechanical action exerted. Conversely, every electric action produced on the circuit of such a system will occasion a displacement of the meniscus, and consequently its movement, which will be more marked in proportion to the smallness of the tube in which the mercury is placed, and to the greatness of the electric action. This electric action may result from a difference of potential in the electric condition of the two extremities of the circuit, which communicate with the electric source employed, or with some electric generator.[8]

[Illustration: FIG. 34.]

In accordance with these effects, it is intelligible that if two tubes T T, pointed at the end, and containing mercury, are plunged into two vessels V V (fig. 34) containing acidulated water and mercury, and metallic wires, P P, Q Q, are used, first to connect the columns of mercury in the tubes, and secondly the layers of mercury at the bottom of the two vessels, the tubes being a little removed from the surface of the mercury in the vessels, we shall then have a metallic circuit, completed by two electrolytes, one of which will be subjected to the mechanical or electrical effects produced in the other. If two vibratory plates B B are placed above the tubes, and one of these is caused to vibrate, the other will reproduce these vibrations, influenced by the vibratory movements communicated by the corresponding column of mercury. The vibrations themselves will be in connection with the electrical discharges resulting from the movements of the column of mercury in the first tube, which are mechanically produced. If an electric generator is introduced into the circuit, the effect which we have just analysed will be caused by modifications in the potential of this generator, in consequence of electro-capillary effects. But if no generator is employed, the action will result from electric currents determined by the electro-capillary attraction itself. In the latter case, however, the instrument must be more delicately made, in order to obtain more sensitive electric reaction, and M. A. Bréguet describes his instrument as follows.

‘The instrument consists of a tube of thin glass, a few centimètres in length, containing alternate drops of mercury and acidulated water, so as to constitute so many electro-capillary elements, connected in tension. The two ends of the tube are fused together, yet so as to allow a platinum wire to touch the nearest drop of mercury on each side. A small circle of thin deal is fixed at right angles to the tube by its centre, thus providing a surface of some extent, which can be applied to the ear when the instrument is a receiver, and to make the tube more mobile under the influence of the voice when the instrument is a sender. The following are the advantages offered by instruments of this construction:--

‘1. They do not involve the use of a battery.

‘2. The disturbing influence of the resistance of a long line is almost destroyed in these instruments, although it is still appreciable in the Bell telephone.

‘3. Two mercury telephones, coupled together as we described above, are absolutely correlative, in this sense, that even different positions in the equilibrium of the mercury in one of them produce different positions of equilibrium in the opposite instrument. It is therefore possible to reproduce at a distance, without a battery, not merely faithful indications of oscillatory movements, which is done by the Bell telephone, but also the exact image of the most general movements.’

Friction Telephones.--Mr. E. Gray has quite recently applied the principle of producing sounds by the friction of animal tissues to the construction of a speaking telephone which may be heard through a whole room, like the singing condenser. He obtains this result by means of clockwork, which causes the rotation of the metallic disk of which we have spoken (p. 23), and on which a piece of skin is so arranged as to produce friction. A carbon or liquid telephone is placed at the sending station, in such a way as to react on an induction coil, as in the systems of Edison, Navez, or Pollard, and speech is reproduced on the rotating disk, and is audible, as we have said, without the necessity of approaching the ear to the instrument.

The best arrangement of the metallic disk on which the animal tissue rubs is that of a cylindrical box, of which the outer lid is made of a thin sheet of zinc with a highly polished, slightly oxidised surface; for the agent of friction, glove-leather slightly moistened with acidulated water may be used, or a sinew of an ox, or skin taken from the ear or tail of a pig.

MODIFICATIONS INTRODUCED IN THE CONSTRUCTION OF THE BELL TELEPHONES.

The modifications which we have been considering relate to the principle of the instrument; those which we have now to consider are only modifications in the form and arrangement of the different organs which form the Bell telephone itself, and which have been designed with the object of increasing the intensity and distinctness of the sounds produced.

Telephones with several diaphragms.--When we remember that the induced currents caused in a magnet result from the vibratory movements of the diaphragm, and that these are produced by the vibrations of the stratum of air interposed between this diaphragm and the vocal organ, it necessarily follows that if these vibrations of the air react on several diaphragms, each attached to its electro-magnetic organ, several induced currents might be caused simultaneously, and if these were properly connected, their effects on the receiver would be so much the more intense, since the sounds produced would result from the combination of several sources of sound. Several inventors, starting from this argument, have planned instruments of varying ingenuity, which we will now describe, but without being able to declare who was the first to realise this idea. It is in fact so simple, that it probably suggested itself to the minds of several inventors at the same time, and we see that while M. Trouvé proposed this improvement in France in November 1877, it was tried in America and discussed in England, where indeed it was not expected to produce very favourable results. Mr. Preece wrote on the subject in a paper entitled 'On some Physical Points connected with the Telephone,' which was published in April 1878. He observes that all the attempts to improve the telephone have ended in disappointment and failure. One of the first attempts of the kind was made by Mr. Wilmot, who expected to obtain favourable results by augmenting the number of diaphragms, helices, and magnets, connecting the helices in a series, and causing them to act simultaneously, so as to increase the energy of the currents developed by the influence of the voice; but experience showed that when the instrument acted directly, the vibratory effect of each of the diaphragms decreased in proportion to their number, and the general effect remained the same as with a single diaphragm. Mr. Wilmot's instrument was made in the beginning of October 1877, and that of M. Trouvé was only an imitation of it.

On the other hand, we see that if the telephones with several membranes were not successful in England, this was not the case in America, for the telephones which experience has shown to give the best results in that country are those of Mr. Elisha Gray and Mr. Phelps, and these have several diaphragms. It is evident that there are details of construction in these instruments which may appear insignificant in theory, and which are notwithstanding very important from a practical point of view, and we believe that it is to this circumstance that instruments of this kind owe their success or failure. Thus, for example, it seems that the vibrations of air caused in the mouthpiece ought to be immediately directed on the surface of the diaphragms by means of distinct channels; it is necessary that the empty space round each diaphragm should be sufficiently limited to prevent echoes and interruptions, unless the case is so large that there is no danger of such effects. Above all, it is necessary that the organs should be fixed in some material unsusceptible of reverberation, and for this reason a preference is given to iron or ebonite. It is certain that when the instrument is properly made, its effects are superior to those of the Bell telephones, and it is asserted in the 'Telegraphic Journal' that experiments were made with one of these instruments before the Royal Society, in London, May 1, 1878, and that the intensity of sound was in proportion to the number of diaphragms. This instrument was designed by Mr. Cox Walker, of York, and possessed eight diaphragms. He considers that this is the arrangement which gives the best results.

[Illustration: FIG. 35.]

Mr. Elisha Gray's System.--Mr. Elisha Gray's last system, which we represent in fig. 35, is one of those which have given the best effects. It is made, as we see, of two telephones, side by side, to which correspond two tubes, issuing from a common mouthpiece E. One of these telephones is seen in section in the plate, the other in elevation, and they correspond to the two branches of a nickel-plated horseshoe magnet N U S, which may serve as a suspension ring. In that part of the plate which represents the section, the induction coil is shown in B, and the magnetic core, of soft iron, in A, which is screwed to the polar end of the magnet S; the vibrating plate is in L L, and, as we see, the tube of the mouthpiece terminates on its surface.

In another model there are four telephones side by side, instead of two, and the effects produced are still more marked.

Mr. Phelps's System.--This system is only deduced from the last, but there are two models of it. In the larger one, which makes it possible to hear as distinctly as if the person with whom conversation is held were speaking in a loud voice in the same room, the two telephones are placed parallel to each other, and so as to present their diaphragms vertically; the space between these two diaphragms is occupied by a vertical tube, terminating at its lower end in a horizontal tube corresponding to the centres of the two diaphragms, and on this tube the mouthpiece is fitted, which projects outside the box in which the instrument is enclosed. The induction coils, and the magnetic cores which traverse them, follow the axis of the system, and seem to constitute the axis of a wheel which is polarised by the poles of a horseshoe magnet, of which the position with reference to the surface of the diaphragms can be regulated by moveable screws. The appearance of the instrument somewhat resembles a gyroscope, resting by a horizontal axis on two shafts which issue from a flattened horseshoe magnet.

Above this system there is the electro-magnetic apparatus of the call-bell, in which there is nothing peculiar, and which is like the German alarums of which we shall speak at the end of this account. This instrument is remarkable for strength and clearness of sound, and especially for its freedom from the Punch and Judy voice so displeasing in other telephones.

Mr. Phelps's small model is in the form of an oblong or elliptical snuff-box, of which the two centres are occupied by two telephonic systems, influenced by the same magnet. This magnet is placed in a horizontal position below the snuff-box, and its poles correspond to the magnetic cores of the coils. These cores are made of iron tubes, split longitudinally in order to destroy irregular induction reactions, and the iron diaphragms rest on five spiral springs, which raise them above the magnetic system. On their other surface the diaphragms are provided with rings of some semi-elastic substance, which prevent the central vibrations of the disks from becoming complicated by those of their edges. The lid, hollowed out in very shallow cavities, is next placed upon the disks, and there are channels of communication in it to serve as a sounding-box. The mouthpiece corresponds to one of these cavities, and the other is closed by a small metallic stopper, which can be withdrawn to regulate the instrument when necessary. Since the vibrations of air are transmitted by the channels to both cavities, the two telephones act together, although at first sight only one of them seems to be required to produce the effect.

Mr. Phelps praises the simultaneous effects produced on the two instruments, which he ascribes, first, to the semi-elastic ring surrounding the rim of each disk, and acting as the hammer of the ear, that is, as a damper; then, to the longitudinal splits of the magnetic core, and lastly to the small size of the cavities left above the vibrating disks. The instrument is made of ebonite, grooved on the surface in order to give a better grasp to the hand.

Mr. Phelps has a new model, called _the crown telephone_, which is now in use in America, together with Mr. Edison's carbon sender. In it each of the two systems of the large model we have described is worked by six horseshoe magnets radiating round the magnetic core, and so arranged that the north poles correspond to this core, and the other poles to the circular rim of the diaphragm. In this way the magnetic field is considerably enlarged, and the sound much intensified.

In experiments recently made at Dr. Wells's church, New York, an assembly of three hundred people were able to hear speech and vocal or instrumental music distinctly in different parts of the hall.

Mr. Cox Walker's System.--This system, on which we have already said a few words, has exactly the arrangement of that by Mr. Elisha Gray. The magnets which act upon the diaphragms are horseshoe, and separate pipes, issuing from a common mouthpiece, direct the vibrations of air on the diaphragms. These, indeed, are only defined parts of one diaphragm, bounded in a circle by mouthpieces corresponding to the air-pipes, and sufficiently restricted on their edges to limit the field of vibration.

M. Trouvé's System.--M. Trouvé has simplified the arrangement of telephones with a double diaphragm, by designing the instrument so as to make Bell's bar magnet react by both poles at once on several disks. For this purpose, he employs a tubular magnet, and winds a helix throughout its whole length, as we see in fig. 36. This magnet is maintained in a fixed position in the centre of a small cylindrical box, of which the base is slightly funnel-shaped, thus acting as a mouthpiece and acoustic tube. It is consequently pierced in the centre with a hole larger at _a_, the station for speaking, than on the opposite side _b_. Between the base and the poles of the magnet there are two vibrating iron plates, M, M′, one of which, M, is pierced with a hole _a_ of the same diameter as the hollow part of the magnet, and consequently smaller than that of the mouthpiece. Finally, several other plates _n_, _n_, _n_, are ranged in parallel lines between these two plates, so that the magnet and its helix may pass through them.

[Illustration: FIG. 36.]

When anything is said before the mouthpiece _a_, the waves of sound encountering the edges of the plate M place it in vibration, and, continuing their passage inside the tubular magnet, they cause the plate M′ to vibrate at the same time as M. A double inducing action therefore takes place on the tubular magnet, and this is translated by the induced currents developed in the helix, which have greater energy since each of the plates intensifies the magnetic effects produced at the pole opposite to the one they influence, which is always the case with bar magnets when the inactive pole is provided with an armature. This advantage may even be obtained in the case of ordinary telephones, if the screw which holds the magnet is placed in contact with a mass of soft iron.

In M. Trouvé's arrangement, the induced currents therefore possess greater energy; but he adds that the sounds reproduced will also be strengthened by the multiplicity of vibratory effects, and by the enlargement of the magnetic effects, which results from a better arrangement of the magnets.

‘When the ear is placed at _a_,’ M. Trouvé writes, ‘it perceives immediately the sounds produced by the first plate M, and those of the second plate reach the ear through the interior of the magnet. This new arrangement is well adapted for an experimental comparison of the results produced by a telephone with a single membrane (a Bell telephone), and those produced by a telephone with several membranes. It is in fact enough to listen at the two faces of the telephone alternately, in order to perceive at once the difference of intensity in the sounds produced. Those collected at _a_, on the side of the pierced iron plate, appear manifestly doubled in intensity compared with those collected at _b_ on the side of the simple membrane which forms the ordinary telephone.

‘The difference is still more striking if, in transmitting or receiving a sound of invariable intensity through a multiple telephone, the unbroken membrane M′ is repeatedly prevented from vibrating.’

Before making this arrangement M. Trouvé had planned another, which he presented to the Académie des Sciences, November 26, 1877, and which we have glanced at in the beginning of this chapter. He describes it in these terms:--

‘In order to increase the intensity of the effects produced in the Bell telephone, I have substituted for the single membrane a cubic chamber, of which each face is, with one exception, formed of a vibrating membrane. Each of these membranes, put in vibration by the same sound, influences a fixed magnet, which is also provided with an electric circuit. In this way, by connecting all the currents generated by the magnets, a single intensity is obtained, which increases in proportion to the number of magnets influenced. The cube might be replaced by a polyhedron, of which the faces might be formed of an indefinite number of vibrating membranes, so as to obtain the desired intensity.’

M. Demoget’s System.--Several other systems of telephones with multiple membranes have been proposed. One of them, planned by M. Demoget, consists in placing before the vibrating disk of the ordinary Bell telephone, separated by the space of a millimètre, one or two similar vibrating disks, taking care to pierce in the centre of the first a circular hole of the same diameter as that of the bar magnet, and to pierce a larger hole in the second membrane. The inventor asserts that the distinctness as well as the intensity of sounds is increased in this way.

‘By this arrangement,’ says M. Demoget, ‘since the vibrating magnetic mass is larger in proportion to the magnet, the electro-motive force of the currents generated is increased, and consequently the vibrations of the disks of the second telephone are more perceptible.’

Mr. McTighe’s Telephone.--In this telephone, which has several diaphragms, there is a horseshoe magnet, and instead of placing the coils upon the poles, there is a single coil fastened to an iron core, which is inserted between wide polar appendices fitted to the two poles of the magnet. These appendices consist of thin plates, which act as vibrating plates.

Modifications in the arrangement of Telephonic Organs.--We see that the forms given to the Bell telephone are very varied, and this is still more the case with its constituent organs, without, however, producing any remarkable improvements. Mr. Preece observes that little has been gained by varying the size and strength of the magnets, and the best effects have been obtained by using the horseshoe magnets directed by Mr. Bell himself. The telephone was certainly introduced into Europe with the arrangement which is theoretically the best, although Mr. Bell is still occupied in improving it. This is also the opinion of M. Hellesen, who, like Mr. Preece, has made many experiments on this point; but this has not deterred several people from declaring that they have discovered the way of making a telephone speak so as to be audible to an assembly of people.

Of the different instruments made with this object, that of M. Righi seems to be the most important. It was lately tried with success at the Académie des Sciences, the Conservatoire des Arts et Métiers, and the Press pavilion of the Exhibition.

[Illustration: FIG. 37.]

The receiver is only a Bell telephone of large size, with a diaphragm of parchment L L (fig. 37), in the centre of which there is a sheet-iron disk F. This membrane is stretched on a large funnel E, which is fixed on a box C C, containing the electro-magnetic coil B: and the magnet N S, much larger than in the ordinary instruments, issues from the box, and serves as its support.

[Illustration: FIG. 38.]

The sender resembles the one represented in fig. 19, except that, instead of liquid, M. Righi employs plumbago mixed with powdered silver, and the platinum needle is replaced by a metallic disk D (fig. 38). The receiver I, which contains the powder, is supported on a spring R, which can be pushed up and down by a regulating screw V, and the whole is fitted into a box C C, and

supported on a foot P. The speaker places himself above the mouthpiece E, and the vibrations transmitted to the membrane L L cause the variations of resistance in I which are necessary for the transmission of speech, as in the Edison system. Two Bunsen cells are enough to set the instrument at work, and it will make the sound of a trumpet or flute audible throughout a room. Vocal music, which is less intense, is necessarily transmitted to a rather less distance, and words spoken in the natural voice are heard by those standing about two yards and a half from the instrument.

The maximum distance at which the instrument has been worked with the battery only is twenty-eight miles, the distance between Bologna and Ferrara, and for greater distances it is necessary to have recourse to induction coils.

In this case, an induction coil is introduced into the circuit at each station, and its primary wire is traversed by a current from the local battery, and so also is the sender, which is elsewhere connected with the receiver by a commutator. The secondary circuit of these coils is completed through the earth and line wire. From this arrangement it follows that the induced current which influences the receiver in correspondence, only produces its effect after a second induction, produced on the primary wire of the local coil, and it appears that this is a sufficient effect; but the advantage of this arrangement is, that it is possible to receive and transmit sounds without the aid of anything but the commutator.

Among other arrangements which have been suggested, we may mention one in which, instead of the bar magnet, a horseshoe magnet is used, with a vibrating plate placed between its poles. For this purpose the poles are tipped with iron, and one of them is pierced with a hole which corresponds to the mouthpiece of the instrument. The two branches of the magnet are also furnished with magnetising helices. When anything is spoken before the hole, the vibrating plate causes induced currents in the two helices: these currents would be of opposite direction if the poles were of like nature, but, since the magnetic poles are of contrary nature, they are in the same direction. The vibrating plate then acts like the two plates of M. Trouvé's instrument, which we have described above.

In another arrangement, lately made by Ader, the receiver is only an ordinary two-branched magnet, of which the armature is supported, at about two millimètres from its poles, by a glass plate to which it is glued, and the plate itself is fastened to two rigid supports. In order to hear it is only necessary to apply the ear to the plate. The sender is a moveable rod of iron or carbon, which rests on a fixed piece of carbon, with no pressure except its own weight, and it supports a concave disk, to which the speaker applies his mouth. These two parts are so arranged as to move horizontally, so that, when the instrument is suspended, the circuit is forcibly disconnected by the fact of its position, and is therefore closed until anyone takes it up to speak. Speech is well reproduced by this system, and may be transmitted to some distance if it is made on a larger scale.

Again, an anonymous inventor, in a little note inserted in 'Les Mondes,' February 7, 1878, writes as follows: 'Since the intensity of the currents produced in the telephone is in proportion to the mass of soft iron which vibrates before the pole of the magnet, and since, on the other hand, the plate is sensitive in proportion to its tenuity, I employ, instead of the ordinary plate, one reduced by nitric acid to the least possible thickness, and I fix it to a circle of soft iron, which keeps it stretched and forms part of the same substance. This circle is placed in a circular opening made inside the compartment. The intensity of a telephone is much increased when such a system replaces the ordinary plate, even at one end of the line.'

In order to obtain vibrating plates of extreme tenuity, M. E. Duchemin thought of employing very thin plates of mica, sprinkled with pulverised iron fixed to the plate by a layer of silicate of potash. The inventor asserts that it is possible to correspond in a low voice with the aid of this system; but it has this inconvenience, that the plate will be broken by speaking too loud.

Professor Jorgenson, of Copenhagen, has also made a Bell telephone which produces very intense sounds, and which has permitted him to observe some curious effects. In this instrument, the magnet is made in a mode analogous to Nicklès' tubular magnets. There is first a cylindrical magnet with a core of soft iron at its upper end, to which the coil is fitted; next, a magnetised tube, formed of a steel ring, which encloses the first magnetic system, and is connected with it by an iron tube. Finally, above the polar extremities of this system, there is the vibrating disk, with the same arrangement as that of ordinary telephones, and of which the superficies is large. If this plate is only a millimètre in thickness, the words spoken can be heard throughout a room; but the sounds lose their clearness when the ear is approached to the vibrating plate, the words are confused, and there is the reverberation which is observed on speaking in a place apt to produce echoes: the listener is, in fact, stunned by the sounds produced. On using a thicker plate--one, for example, of three or four millimètres--the telephone only produces the effect of the ordinary instruments, and it is necessary to apply the ear to it.

M. Marin Maillet, of Lyons, has suggested that the sounds reproduced by the telephone might be increased by reflecting them through a certain number of reflectors, which, by concentrating them in a focus on a resonator, would considerably enlarge them.

Since this idea was not accompanied by experiments, it can hardly be regarded as serious.

TELEPHONIC EXPERIMENTS.

Since Mr. Bell's experiments of which an account has been given in the early part of this work, much study has been given by men of science and inventors to the effects produced in this curious instrument, so as to ascertain its theory and deduce improvements in its construction. We will take a glance at these researches in succession.

Experiments on the Effects produced by Voltaic and Induced Currents.--The comparative study of the effects produced in the telephone by voltaic and induced currents was one of the first and most important. In 1873, as we have seen, Mr. Elisha Gray converted the voltaic currents, which he employed to cause the vibrations of his transmitting plate, into induced currents by means of an induction coil, such as Ruhmkorff's. The voltaic currents then traversed the primary helix of the coil, and the induced currents reacted on the receiving instrument, producing on its electro-magnetic system the vibrations excited at the sending station. When Mr. Edison designed his battery telephone, he had recourse to the same means to work his receiving telephone, since he had ascertained that induced currents were superior to voltaic currents. But this peculiarity of Mr. Edison's arrangement was not clearly understood from the descriptions which reached Europe, so that several persons believed that they had invented this arrangement--among others, Colonel Navez and MM. Pollard and Garnier.

Colonel Navez, in an interesting paper on the new telephonic system, presented to the Belgian Royal Academy, February 2, 1878, only suggests this arrangement as a mode of reproducing speech at a great distance; but he quotes no experiment which distinctly shows the advantages of this combination. Twenty days later, MM. Pollard and Garnier, unacquainted with Colonel Navez's researches, sent to me the results they had obtained by similar means, and these results appeared to me so interesting that I communicated them to the Académie des Sciences, February 25, 1878. In order that the importance of these results may be clearly understood, I will repeat the text of M. Pollard's letter, addressed to me on February 20, 1878:

'With the object of increasing the variations of electric intensity in the Edison system, we induce a current in the circuit of a small Ruhmkorff coil, and we fix the receiving telephone to the extremities of the induced wire. The current received has the same intensity as that of the inducing current, and consequently the variations produced in the current which works the telephone have a much wider range. The intensity of the transmitted sounds is strongly increased, and the value of this increase depends upon the relative number of spirals in the inducing and induced circuits. Our attempts to determine the best proportions have been laborious, since it is necessary to make a coil for each experiment; we have hitherto obtained excellent results with a small Ruhmkorff coil reduced to its simplest form, that is, without condenser or contact-breaker. The inducing wire is No. 16, and is wound in five layers; the induced wire is No. 32, and in twenty layers. The length of the coil is seven centimètres.

'The following is the most remarkable and instructive experiment: When setting the sender to work with a single Daniell cell, there is no appreciable effect at the receiving station, at least in the telephone which I have made, when it is in immediate connection with the circuit; after inserting the small induction coil, sounds become distinctly audible, and their intensity equals that of good ordinary telephones. Since the battery current is only moderately intense, the points of plumbago are not worn down, and the regulating apparatus lasts for a long while. When a stronger battery is used, consisting of six cells of bichromate of potash (in tension) or twelve Leclanché cells, sufficient intensity is obtained by the direct action to make sounds nearly as audible as in ordinary telephones; but when the induction coil is inserted, the sounds become much more intense, and may be heard at a distance of from fifty to sixty centimètres from the mouthpiece. Songs may, under such circumstances, be heard at a distance of several yards; but the relative increase does not appear to be so great as in the case of the single Daniell cell.'

On the other hand, 'Les Mondes,' March 7, 1878, contains an account of a series of experiments made by Signor Luvini, Professor of Physics at the Military Academy of Turin, which proved that the introduction of electro-magnets into the circuit which connects the two telephones sensibly increases the intensity of sound. The maximum effect is produced by placing one close to the transmitting, and the other close to the receiving telephone, and the introduction of other magnets is of no use. The inducing wire of a Ruhmkorff coil, when introduced into such a circuit, excited no sensible effects of induction in the induced circuit, and consequently could not set the telephone in connection with this circuit at work. But the current of a Clarke machine produces sounds resembling the beats of a drum, which are deafening when the ear is applied to the instrument: they become very faint, however, at the distance of a mètre. The currents of a Ruhmkorff machine are still more energetic, and the sound fills a whole room. By modifying the position of the lever of the coil, the sound passes through different tones, which are always in unison with the breaks of the current, at least up to a certain pitch.

This property of currents induced by the Ruhmkorff coil has enabled M. Gaiffe to obtain by their means a very simple mode of regulating telephones, so as to produce in them the maximum amount of sensibility. For this purpose he places the telephone he proposes to regulate in the circuit of an induction instrument with moveable helices and graduated intensities. The sounds which result from the vibrator are then reverberated from the telephone, and are audible at a distance from the instrument; by using a screw-driver, it is possible to adjust the screw to which the free end of the bar magnet of the instrument is fixed. It can be tightened or loosened, so as to advance or withdraw the other end of the magnet from the vibrating plate of the telephone, and the process is repeated until the maximum intensity of sound is obtained.

On the other hand, as the sounds given out by the two telephones in correspondence are intense in proportion to the degree of unison in the vibrations produced by them, it is necessary to select those which emit the same sounds for the same given note; and the mode we have just described may be employed with advantage, since it will be enough to observe what instruments give the same note in the condition of maximum sensibility, when regulated in the same way by the induction machine.

It is very important that the telephones in correspondence should be well matched, not only to ensure clear transmissions, but also with reference to the tone of voice of those who are to use it. The sound becomes more audible when the tone of voice corresponds to the telephonic tone; and for this reason some telephones repeat the voices of women and children better than those of men, and with others the reverse takes place.

The telephonic vibrations vary in different instruments, and these variations may be noted in the way we have indicated.

The advantages of induced currents in telephonic transmissions may be easily understood, if we consider that the variations of resistance in the circuit, resulting from the greater or less range in the vibrations of the transmitting plate, are of constant value, and can only manifest their effects distinctly in short circuits; consequently the articulate sounds which result from them can only be really appreciable in circuits of great resistance. According to Mr. Warren de la Rue's experiments (reported in the 'Telegraphic Journal,' March 1, 1878), the currents produced by the vibrations of the voice in an ordinary telephone represent in intensity those of a Daniell cell traversing 100 megohms of resistance (or 10,000,000 kilomètres); and it is plain that the simple question of greater or less intensity in the currents acting on the receiving telephone is not the only thing we have to consider. With an energetic battery, it is evident, in fact, that the differential currents will always be more intense than the induced currents produced by the action of the instrument. I myself am inclined to believe that induced currents owe the advantages they possess to the succession of inverse currents and their brief duration. These currents, of which M. Blaserna considers that the duration does not exceed 1/200 of a second, are much more susceptible than voltaic currents of the multiplied vibrations which are characteristic of phonetic vibrations, and especially since the succession of inverse currents which take place discharge the line, reverse the magnetic effects, and contribute to make the action more distinct and rapid. We cannot therefore be surprised that the induced currents of the induction coil, which can be produced under excellent conditions at the sending station, since the circuit of the voltaic current is then very short, are able to furnish results, not only more effective than the voltaic currents from which they take their origin, but even than the induced currents resulting from the action of the Bell telephone, since they are infinitely more energetic.

As for the effects produced by the currents of Bell telephones, which are relatively great when we consider their size, they are easily explained from the fact that they are produced under the influence of the vibrations of the telephone plate, so that their variations of intensity always maintain the same proportion, whatever may be the resistance of the circuit, and consequently they are not effaced by the distance which divides the two telephones.

Experiments on the part taken by the different telephonic organs in the transmission of speech.--In order to introduce all the improvements of which a telephone is capable, it is important to be quite decided as to the effects produced in the several parts of which it is composed, and as to the part taken by the several organs which are at work. To attain this object several men of science and engineers have undertaken a series of experiments which have produced very interesting results.

One of the points on which it was most important to throw light was that of ascertaining whether the vibrating plate used in their telephone receivers by Messrs. Bell and Gray is the only cause of the complex vibrations which reproduce speech, or if the different parts of the electro-magnetic system of the instrument all conduce to this effect. The experiments made by Mr. Page in 1837 on the sounds produced by the resonant electro-magnetic rods, and the researches pursued in 1846 by Messrs. de la Rive, Wertheim, Matteucci, &c., on this curious phenomenon, allow us to state the question, which is certainly more complex than it at first appears.

In order to start from a fixed point, it must first be ascertained whether a telephone can transmit speech without a vibrating plate. Experiments made by Mr. Edison[9] in November 1877, with telephones provided with copper diaphragms, which produced sounds, make the hypothesis credible; and it received greater weight from the experiments made by Mr. Preece and Mr. Blyth. The fact was placed beyond a doubt by Mr. Spottiswoode (see the 'Telegraphic Journal' of March 1, 1878), who assures us that the vibrating plate of the telephone may be entirely suppressed without preventing the transmission of speech, provided that the polar extremity of the magnet be placed quite close to the ear; and it was after this that I presented to the Académie des Sciences my paper on the theory of the telephone, which led to an interesting discussion of which I shall speak presently. At first the authenticity of these results was denied, and then an attempt was made to explain the sounds heard by Mr. Spottiswoode as a mechanical transmission of the vibrations, effected after the manner of string telephones; but the numerous experiments which have subsequently been made by Messrs. Warwick, Rossetti, Hughes, Millar, Lloyd, Buchin, Canestrelli, Wiesendanger, Varley, and many others, show that this is not the case, and that a telephone without a diaphragm can transmit speech electrically.

Colonel Navez himself, who had first denied the fact, now admits that a telephone without a diaphragm can emit sounds, and even, under certain exceptional conditions, can reproduce the human voice; but he still believes that it is impossible to distinguish articulate words.

This uncertainty as to the results obtained by the different physicists who have studied the matter shows that at any rate the sounds thus reproduced are not clearly defined, and that in physical phenomena, only appreciable to our senses, the appreciation of an effect so undefined must depend on the perfection of our organs. We shall presently see that this very slight effect can be largely increased by the arrangement adopted by Messrs. Bell and Gray, and we shall also see that, by a certain mode of magnifying the vibrations, it has been decisively proved that a telephone without a diaphragm can readily reproduce speech. I proceed to give the description of such a telephone, which was shown by Mr. Millar at the meeting of the British Association at Dublin in August 1878.

This instrument consists of a small bar magnet, three inches in length and 5/16 of an inch in width and thickness, and a copper helix (No. 30) of about six mètres in length is wound round the bar. It is fixed in a box of rather thick pasteboard, fitted above and below with two zinc plates, which render it very portable. With a telephonic battery sender and a single Leclanché cell, speech can be perfectly transmitted; the whistling of an air, a song, and even the act of respiration become audible. It seems also that the instrument can act without a magnet, merely with a piece of iron surrounded by the helix; but the sounds are then much fainter.

Signor Ignace Canestrelli obtained the same results by making one of the carbon telephonic senders react on a telephone without a diaphragm, by means of an induction coil influenced by two Bunsen cells. He writes as follows on the subject:

'With this arrangement I was able to hear the sound of any musical instrument on a telephone without a diaphragm: singing, speaking, and whistling were perfectly audible. Whistling could be heard, even when the telephone without a diaphragm was placed at some distance from the ear. In some cases, depending on the pitch of the voice, on the distance of the sending station, and on the joint pressure exerted by the carbons, I could even distinguish words.

'I finally discharged the currents of the transmitter into the coils of insulated copper wire with which the two poles of a magnet were provided. This magnet was placed on a musical box, made of very thin slips of wood, and on placing the ear at the opening of the box I obtained the same results as with the ordinary telephones without a diaphragm.'

M. Buchin, after repeating experiments of the same kind as the above, intimates that it is easy to hear the sounds produced by a telephone without a diaphragm, by introducing into the ear the end of an iron rod, of which the other end is applied to the active pole of the bar magnet of the telephone. (See 'Le Journal d'Electricité,' October 5, 1878.)

I repeat finally the account of some experiments made by Mr. Hughes and M. Paul Roy which are interesting from our present point of view.

1. If an armature of soft iron is applied to the poles of an electro-magnet, with its two branches firmly fixed on a board, and if pieces of paper are inserted between this armature and the magnetic poles, so as to obviate the effects of condensed magnetism; if, finally, this electro-magnet is connected with a speaking microphone, of the form given in fig. 39, it is possible to hear the words spoken in the microphone on the board which supports the electro-magnet.

2. If two electro-magnets are placed in communication with a microphone, with their poles of contrary signs opposite to each other, and if their poles are separated by pieces of paper, speech will be distinctly reproduced, without employing armature or diaphragm. These experiments are, however, delicate, and demand a practised ear.

3. If, instead of causing the current produced by a microphone to pass through the helix of a receiving telephone, it is sent directly into the bar magnet of this telephone in the direction of its axis--that is, from one pole to another--the words pronounced in the microphone may be distinctly heard. This experiment by M. Paul Roy indicates, if it is exact, that the electric pulsations which traverse a magnet longitudinally will modify its magnetic intensity. The experiment, however, demands verification.

Another point was obscure. It was important to know whether the diaphragm of a telephone really vibrates, or at least if its vibrations could involve its displacement, such as occurs in an electric vibrator, or in wind instruments which vibrate with a current of air. M. Antoine Bréguet has made some interesting experiments on the subject, which show that such a movement cannot take place, since speech was reproduced with great distinctness from telephones with vibrating plates of various degrees of thickness, and he carried the experiment so far as to employ plates fifteen centimètres in thickness.[10] When pieces of wood, caoutchouc, and other substances were laid upon these thick plates, the results were the same. In this case it cannot be supposed that the plates were moved to and fro. I have moreover ascertained, by placing a layer of water or of mercury on these plates, and even on thin diaphragms, that no sensible movement took place, at least when the induced currents produced by the action of speaking were used as the electric source. No ripples could be seen on the surface of the liquid, even when luminous reflectors were employed to detect them. And indeed it can hardly be admitted that a current not more intense than that of a Daniell element, which has traversed 10,000,000 kilomètres of telegraphic wire--a current which can only show deviation on a Thomson galvanometer--should be powerful enough to make an iron plate as tightly stretched as that of a telephone vibrate by attraction, even if we grant that the current was produced by laying a finger on the diaphragm.

Very nice photographic experiments do, however, show that vibrations are produced on the diaphragm of the receiving telephone; they are indeed excessively slight, but Mr. Blake asserts that they are enough to cause a very light index, resting on the diaphragm, to make slight inflections on a line which it describes on a register. Yet this small vibration of the diaphragm does not show that it is due to the effect of attraction, for it may result from the act of magnetisation itself in the centre of the diaphragm.[11] An interesting experiment by Mr. Hughes, repeated under different conditions by Mr. Millar, confirms this opinion.

If the magnet of a receiving telephone consists of two magnetised bars, perfectly equal, separated from each other by a magnetic insulator, and they are so placed in the coil as to bring alternately the poles of the same and of contrary signs opposite to the diaphragm, it is known that the telephone will reproduce speech better in the latter case than in the former. Now, if the effects were due to attraction, this would not be the case; for the actions are in disagreement when the poles of contrary signs are subjected to the same electric influence, while they are in agreement when these poles are of like signs.

On the other hand, it is known that if several iron plates are put together in order to form the diaphragm of the receiver, the transmission of sounds is much stronger than with a simple diaphragm; and yet the attraction, if it has anything to do with it, could only be exerted on one of the diaphragms.

It further appears that it is not merely the magnetic core which emits sounds, but that they are also produced with some distinctness by the helices. Signor Rossetti had already ascertained this fact, and had even remarked that they could be animated by a slight oscillatory movement along the bar magnet, when they were not fixed upon it. Several observers, among others M. Paul Roy, Herr Wiesendanger, and Signor Canestrelli, have since mentioned similar facts, which are really interesting.

‘If,’ writes M. Paul Roy, ‘a coil of fine wire, which is at the extremity of the bar magnet of a Bell telephone, receives the pulsatory currents transmitted by a carbon telephone, it is only necessary to bring the coil close to the ear in order to hear the sounds.

‘The sounds received in this way are very faint, but become much stronger if a piece of iron is introduced into the circuit coil. A magnet acts with still greater force, even when it consists of a simple magnetised needle. Finally, the sound assumes its maximum intensity when an iron disk is inserted between the ear and the coil.

‘By placing the end of the coil to the ear, and sending a current through it from the bar magnet, it is ascertained that the sound is at its minimum when the neutral line of the magnet is enclosed by the coil, and that it increases until attaining its maximum, when the magnet is moved until one of its poles corresponds to the coil.

‘This fact of the reproduction of sounds by a helix is universal. Every induction coil and every electro-magnet are capable of reproducing sound when the currents of the sender are of sufficient intensity.’

Signor Canestrelli writes as follows: ‘With the combination of a carbon telephone and one without diaphragm or magnet--that is, with only a simple coil--I was able to hear whistling through the coil, placed close to the ear. This coil was of very fine copper wire,

and the currents were produced through an induction coil by two Bunsen elements. The contacts of the telephone were in carbon, and it was inserted in the primary circuit.

‘I fastened the coil to the middle of a tightly stretched membrane which served as the base of a short metal cylinder. When a magnet was placed near this part of the coil, the sounds were intensified, and when I fixed the magnet in this position, I could hear what was said.

‘I afterwards substituted for the magnet a second coil, fastened to a wooden bar, and on causing the induced currents to pass into both coils at once I was able to hear articulate speech, although not without difficulty.

‘Under these latter conditions I found it possible to construct a telephone without a magnet, but it required a strong current, and it was necessary to speak into the sender in a special manner, so as to produce strong and concentrated sounds.’

Another very interesting experiment by M. A. Bréguet shows that all the constituent parts of the telephone--the handle, the copper rims, and the case, as well as the diaphragm and the electro-magnet--can transmit sounds. M. Bréguet ascertained this fact by the use of string telephones, which he attached to different parts of the telephone on which the experiment was made. In this way he was not only able to establish a correspondence between the person who worked the electric telephone and the one who was listening through the string telephone, but he also made several string telephones act, which were attached to different parts of the electric telephone.

These two series of experiments show that sounds may be obtained from different parts of the telephone without any very appreciable vibratory movements. But Signor Luvini wished for a further assurance of the fact, by ascertaining whether the magnetisation of any magnetic substance, followed by its demagnetisation, would involve a variation in the form and dimensions of this substance. He consequently caused a large tubular electro-magnet to be made, which he filled with a quantity of water, so that, when its two ends were corked, the liquid should rise in a capillary tube fitted to one of the corks. In this way the slightest variations in the capacity of the hollow part of the electro-magnet were revealed by the ascent or descent of the liquid column. He next sent an electric current of varying intensity through the electro-magnet, but he was never able to detect any change in the level of the water in the tube; although by this arrangement he could measure a change of volume of 1/30 of a cubic millimètre. It appears from this experiment that the vibrations produced in a magnetic substance under the influence of successive magnetisations and demagnetisations, are wholly molecular. Yet other experiments made by M. Canestrelli seem to show that these vibrations are so far sensible as to produce sounds which can be detected by the microphone. He writes as follows on the subject:

‘When the broken currents of an induction coil are discharged into a coil placed on a sounding-box, it is possible to hear at a little distance the sounds produced by the induced currents thus generated. On approaching the magnet to the opening of the coil, these sounds are intensified, and the vibrations of the magnet become sensible to the touch; this vibration might even be made visible by suspending the magnet inserted into the coil to a metallic wire, which is fitted to a membrane stretched on a drum, and the latter will then reproduce sounds. When the same magnet is suspended to a microphone, it is possible, with the aid of a telephone, to ascertain the same effects, which are then increased.’

We shall presently consider how these different deductions are to be interpreted, so as to render the true theory of the telephone intelligible; but, before doing so, we will mention some other experiments which are not without interest.

We have seen that the experiments of Messrs. Edison, Blyth, and Preece, show that sounds may be reproduced by a telephone with a diaphragm made of some unmagnetic substance, and they also show, which is still more curious, that these sounds may be transmitted under the influence of induced currents produced by these diaphragms when they are placed in vibration before the magnet. Messrs. Edison and Blyth had already adduced this fact, which was received with incredulity, but it has been confirmed by Mr. Warwick in an article published in the ‘English Mechanic.’ He writes that in order to act upon the magnet, so as to produce induced currents, something possessed of greater energy than gas must first be made to vibrate. It is not, however, necessary that this substance should be magnetic, for diamagnetic substances act perfectly.[12] Mr. Preece sought for the cause in the induced currents developed in any conducting body when a magnet is moved before it, currents which give rise to the phenomenon discovered by Arago and known by the name of magnetism by rotation. Yet these facts do not appear to us to be sufficiently well established to make the theory worthy of serious consideration, and it is possible that the effects observed resulted from simple mechanical transmissions.

To conclude the account of these experiments, we will add that Mr. W. F. Barrett thinks it somewhat difficult to define the mode of vibration of the diaphragm, since, while a certain amount of compression exerted on the iron destroys the sounds resulting from the peculiar effects of magnetisation, a still stronger compression causes them to reappear. It is certain that the question is full of obscurity, and demands great research: it is enough to have shown that the theory hitherto held is insufficient.

On the other hand, Colonel Navez considers that the intensity of sound reproduced in a telephone depends not only on the range of vibrations, but also on the vibrating surface and the effect it produces on the stratum of air which transmits the sound. (See paper by Colonel Navez in the 'Bulletin de l'Académie de Belgique,' July 7, 1878.)

Experiments on the Effects which result from Mechanical Shocks communicated to different parts of a Telephone.--If a piece of iron is applied to the screw which holds the magnet of the ordinary telephone, it is observed that the transmitted sounds are more distinct, owing to the force supplied to the active pole of the magnet; but at the moment when the piece of iron is applied to the screw a distinct noise is heard, which seems to be due to the mechanical vibrations caused in the magnet at the moment of the shock. M. des Portes, a lieutenant in the French navy, has lately made some interesting experiments on this class of phenomena. He has observed that if, in a telephonic circuit of 90 yards completed by the earth, the sending telephone is reduced to a simple magnet, provided with the coil which constitutes its electro-magnetic organ, and if this magnet is suspended vertically by a silken thread, with the coil above it, a blow struck upon the magnet, either by a copper rod or a piece of wood, will cause distinct sounds to be produced in the receiving telephone--sounds which will increase in intensity when the blow is struck close to the coil, and which will become still stronger, but less clear, if a vibrating plate of soft iron is placed in contact with the upper pole of the magnet.

When the striking instrument is made of iron, the sounds in question are more strongly marked than if it is of wood, and when the magnet has a vibrating disk applied to its active pole, a vibration of the disk takes place at the moment when the shock is heard.

If the striking body is a magnet, the sounds produced resemble those obtained when it is of iron, if the effect is produced between poles of the same nature; but if the poles are of contrary natures, a second noise is heard after each blow, which is produced by drawing away the magnet, and which appears to be a blow struck with much less force. The sound is of course increased if the magnet is provided with its vibrating disk.

If words are uttered on the vibrating disk of the sending telephone, when it is applied to the pole of the magnet, various sounds are heard on the receiving telephone, somewhat similar to those produced by vibrating one of the strings of a violin, and the sound made in withdrawing the disk from contact with the magnet is distinctly heard in the receiver.

The person who applies his ear to the vibrating disk of the sender when it is arranged as above, may hear the voice of anyone who speaks into the receiver, but cannot distinguish the words, owing, no doubt, to the condensed magnetism at the point of contact between the magnet and the vibrating disk, which slackens the magnetic variations and makes it more difficult for them to take place.

A coil is not necessary in order to perceive the blows struck upon the magnet with a rod of soft iron. It is enough to wind three turns of naked conducting wire, which acts as line wire, round one end of the magnet, and the sounds perceived cease, as in other experiments, when the circuit is broken, plainly showing that they are not due to mechanical transmission. It is a still more curious fact that if the magnet is placed in the circuit, so as to form an integral part of it, and if the two ends of the conducting wire are wound round the ends of the magnet, the blows struck upon the latter with the soft iron rod are perceived in the telephone as soon as one pole of the magnet is provided with a vibrating disk.

I have myself repeated M. des Portes' experiments by simply striking on the screw which, in ordinary telephones, fastens the magnet to the instrument, and I have ascertained that, whenever the circuit was complete, the blows struck with an ivory knife were repeated by the telephone: they were, it is true, very faint when the vibrating disk was removed, but very marked when the disk was in its place. On the other hand, no sound was perceived when the circuit was broken. These sounds were louder when the blows were struck upon the screw than when they were struck on the pole of the magnet itself above the coil: for this reason, that in the first case the magnet could vibrate freely, while in the second the vibrations were stifled by the fixed position of the bar magnet.

These effects may be to some extent explained by saying that the vibrations caused in the magnet by the shock produce undulatory displacements of the magnetised particles in the whole length of the bar, and that induced currents would, according to Lenz's law, result in the helix from these displacements--currents of which the force would increase when the power of the magnet was further excited by the reaction of the diaphragm, which acts as an armature, and also by that of the striking instrument when it

also is magnetic. Yet it is more difficult to explain M. des Portes' later experiments, and the effect may be produced by something more than the ordinary induced currents.

These are not the only experiments which show the effects produced under the influence of molecular disturbance of various kinds. Mr. Thompson, of Bristol, has observed that if a piece of iron and a tin rod placed perpendicularly on the iron are introduced into the circuit of an ordinary telephone, it is enough to strike the tin rod in order to produce a loud sound in the telephone. He has also shown that if the two ends of a bar magnet are enclosed by two induction coils which are placed in connection with the circuit of a telephone, and if the flame of a spirit lamp is moved below the magnet in the space dividing the two coils, a distinct sound is heard as soon as the flame exerts its influence on the bar magnet. This effect is undoubtedly due to the weakening of the magnetic force of the bar which is produced by the action of heat. I have myself observed that a scratching sound on one of the wires which connect the telephones is heard in both of them, at whatever point in the circuit the scratch is made. The sounds produced are indeed very faint, but they can be distinctly heard, and they become more intense when the scratch is made on the binding-screws of the telephone wires. These sounds cannot result from the mechanical transmission of vibrations, since they are imperceptible when the circuit is broken. From these experiments it appears that some sounds which have been observed in telephones tried on telegraph stations may arise from the friction of the wires on their supports--a friction which produces those very intense sounds which are sometimes heard on telegraphic wires.

Theory of the Telephone.--It appears from the several experiments of which we have spoken that the explanation generally given of the effects produced in the telephone is very imperfect, and that the transmission of speech, instead of resulting from the repetition by the membrane of the receiving telephone (influenced by electro-magnetism) of vibrations caused by the voice on the membrane of the transmitting membrane, is due to molecular vibrations produced in the whole electro-magnetic system, and especially on the magnetic core contained in the helix. These vibrations must be of the same nature as those which have been observed in resonant electro-magnetic rods by MM. Page, de la Rive, Wertheim, Matteucci, &c., and these have been employed in telephones by Reiss, by Cecil and Leonard Wray, and by Vanderweyde.

According to this hypothesis, the principal office of the vibrating plate consists in its reaction, in order to produce the induced currents when the voice has placed it in vibration, and by this reaction on the polar extremity of the bar magnet it strengthens the magnetic effects caused in the centre of the bar when it vibrates under the electro-magnetic influence, or at least when it is affected by the magnet. Since the range of these vibrations for a single note is great in proportion to the flexibility of the note, and since, on the other hand, the variations in the magnetic condition of the plate are rapid in proportion to the smallness of its mass, the advantage of employing, as Mr. Edison has done, very thin and relatively small plates is readily understood. In the case of transmission, the wider range of vibration increases the intensity of the induced currents transmitted. In the case of reception the variations in the magnetising force which produces the sounds are rendered clearer and more distinct, both in the armature membrane and in the bar magnet: something is gained, therefore, in each case. This hypothesis by no means excludes the phonetic effects of the mechanical and physical vibrations which may be produced in the armature plate under the influence of magnetisation and demagnetisation to which it is subjected, and these join their influence to that of the magnetic core.

What is the nature of the vibrations sent into the receiving telephone? This question is still obscure, and those who have studied it are far from being in agreement: as early as 1846 it was the subject of an interesting discussion between MM. Wertheim and de la Rive, and the new discoveries render it still more complex. M. Wertheim considers that these vibrations are at once longitudinal and transverse, and arise from attractions exchanged between the spirals of the magnetising helix and the magnetic particles of the core. M. de la Rive holds that in the case we are considering the vibrations are simply longitudinal, and result from molecular contractions and expansions produced by the different combinations assumed by the magnetic molecules under the influence of magnetisation and demagnetisation. This appears to us to be the most natural explanation, and it seems to be confirmed by the experiment made by M. Guillemin in 1846. M. Guillemin ascertained that if a flexible iron rod, surrounded by a magnetising helix, is kept in position by a vice at one end, and bent back by a weight at the other, it can be made to return instantly to its normal position by sending a current through the magnetising helix. This recovery can in such a case be due to nothing but the contraction caused by the magnetic molecules, which, under the influence of their magnetisation, tend to produce intermolecular attractions, and to modify the elastic conditions of the metal. It is known that when iron is thus magnetised it becomes as hard as steel, and a file makes no impression on its surface.

It is at any rate impossible to dispute that sounds are produced in the magnetic core, as well as in the armature, under the influence of intermittent electric action. These sounds may be musical or articulate; for as soon as the sender has produced the electric

action required, there is no reason why vibrations which are effected in a transverse or longitudinal direction should transmit the one more than the other. These vibrations may, as we have seen, be termed microscopic.

Signor Luvini, who shares our opinion of the foregoing theory, does not, however, think it wholly satisfactory, unless account is taken of the reaction caused by the bar magnet on the helix which surrounds it. ‘There cannot,’ he says, ‘be _action_ without _reaction_, and consequently the molecular action produced in the magnet ought to cause corresponding variations in the helix, and these two effects ought to contribute to the production of sounds.’ He supports this remark by a reference to Professor Rossetti’s experiment, of which we have spoken above.

We believe, however, that this double reaction of which Signor Luvini speaks is not indispensable, for we have seen that insulated helices can produce sounds; it is true that the spirals, reacting on each other, may be the cause of this.

The difficulty of explaining the production of sounds in an electro-magnetic organ destitute of armature caused the authenticity of the experiments we have described to be at first denied, and Colonel Navez started a controversy with us which is not likely to be soon terminated; yet one result of this controversy is that Colonel Navez was obliged to admit _that the sound of the human voice may be reproduced by a telephonic receiver without a disk_. But he still believes that this reproduction is so faint that it is not possible to recognise articulate words, and he maintains that the transverse vibrations of the disk, which are due to effects of attraction, are the only ones to reproduce articulate speech with such intensity as to be of any use.

It is certain that the articulation of speech requires a somewhat intense vibration which cannot easily be produced in a telephone without a diaphragm; for it must be remembered that in an instrument so arranged, the magnetic effects are reduced in a considerable ratio, which is that of the magnetic force developed in the magnet, multiplied by itself, and that so faint an action as that effected in a telephone becomes almost null when, in consequence of the suppression of the armature, it is only represented by the square root of the force which produced it. It is therefore possible that the sounds which are hardly perceptible in a telephone without a diaphragm become audible when the cause which provokes them is multiplied by itself, and when there are in addition the vibrations produced in the heart of the armature itself, influenced by the magnetisations and demagnetisations to which it is subjected.

In order to show that the action of the diaphragm is less indispensable than Colonel Navez seems to imagine, and that its vibrations are not due to electro-magnetic attractions, it will be enough to refer to Mr. Hughes’s experiments, which we have mentioned above. It is certain that if this were the effect produced, we should hear better when the two bar magnets present their poles of the same nature before the diaphragm, than when they present the poles of contrary natures, since the whole action would then converge in the same direction. Again, the more marked effects obtained with multiple diaphragms in juxtaposition completely exclude this hypothesis. It is, however, possible that in electro-magnetic telephones the iron diaphragm, in virtue of the rapid variations of its magnetic condition, may contribute to render the sounds clearer and more distinct; it may react in the way the tongue does; but we believe that the greater or less distinctness of the articulate sounds must be chiefly due to the range of vibrations. Thus Mr. Hughes has shown that the carbons of metallised wood employed in his microphonic speakers were to be preferred to retort carbons for the transmission of speech, for the very reason that they had less conductivity, so that the differences of resistance which result from differences of pressure are more marked, and consequently it is easier to seize the different degrees of vocal sounds which constitute articulate speech.

It must be clearly understood that what we have just said only applies to the Bell telephone, that is, to a telephone in which the electric currents have such a faint intensity that it cannot be supposed there is any external attractive effect. When these currents are so energetic as to produce such an effect, a transverse electro-magnetic vibration certainly takes place, which is added to the molecular vibration, and helps to increase the sounds produced. But it is no less true that this transverse vibration by attraction or by movement of the diaphragm is not necessary for the reproduction of sounds, whether musical or articulate.

We are not now concerned with the discussion of magnetic effects; there has been an advance in science since Colonel Navez started the controversy, and we must ask how his theory of the movements of the telephone diaphragm by attraction will explain the reproduction of speech by a receiving microphone destitute of any electro-magnetic organ, and I can assert that my experiments show that there can be no mechanical transmission of vibrations, since no sound is heard when the circuit is broken or deprived of its battery. Colonel Navez must therefore accept the molecular vibrations. This certainly gives us a new field for study; but it is because European men of science persist in remaining bound by incomplete theories that we have allowed the Americans who despise them to reap the glory of the great discoveries by which we have lately been astonished.

The experiments quoted above show that sounds may be reproduced not only by simple helices without an electro-magnetic organ, but also by the plates of a condenser, in spite of the pressure exerted upon them; and when we add to this the effects I have just pointed out, it may be supposed that vibrations of sound must result from every reaction between two bodies which has the effect of producing abruptly and at close intervals modifications in the condition of their electric or magnetic equilibrium. It is known that the presence of ponderable matter is necessary for the production of electric effects, and it is possible that the molecular vibrations of which I have spoken may be the result of molecular movements, due to the variations of the electric force which holds the molecules in a special condition of reciprocal equilibrium.

In conclusion, the theory of the telephone and microphone, considered as reproductive organs of speech, is still far from being perfectly clear, and it would be imprudent to be too positive on questions of such recent origin.

The theory of the electric transmission of sounds in electro-magnetic telephones is somewhat complex. It has been seen that they can be obtained from diaphragms of non-magnetic substance, and even from simple mechanical vibrations produced by shocks. Are we to ascribe them in the first case to the inductive reaction of the magnet on the vibrating plate, and in the second case to the movements of magnetic particles before the spirals of the helix? The matter is still very obscure; yet it is conceivable that the modifications of the inducing action of the magnet on the vibrating diaphragm may involve variations in the magnetic intensity, just as we can admit an effect of the same kind due to the approach and withdrawal of the magnetic particles of the spirals of the helix; M. Trève, however, believes that there is in the latter case a special action, which he has already had occasion to study under other circumstances, and he sees in the current thus caused the effect of the transformation of the mechanical labour produced amidst the magnetic molecules. The question is complicated by the fact that these effects are often produced by purely mechanical transmissions.

There is another point to consider, on which Colonel Navez has made some interesting remarks; that is, whether the effects in the receiver are stronger with permanent than with temporary magnets. In the first model of the telephone, exhibited by Mr. Bell at Philadelphia, the receiver was, as I have said, made of a tubular electro-magnet, furnished with a vibrating disk at its cylindrical pole; but this arrangement was abandoned by Mr. Bell, with the object, as he states in his paper, of rendering his instrument both a receiver and a sender.[13] Yet Colonel Navez maintains that the magnet plays an important part, and is even indispensable under the present conditions of its form. ‘It is possible,’ he says, ‘under certain circumstances, and by making the instrument in a special way, to make a Bell receiver speak without a permanent magnet, yet with an instrument of the usual construction the sound ceases when the magnet is withdrawn and replaced by a cylinder of soft iron. In order to restore the voice of the telephone, it is enough to approach the pole of a permanent magnet to the cylinder of soft iron. It follows from these experiments that a Bell telephone cannot act properly unless the disk is subjected to an initial magnetic tension obtained by means of a permanent magnet. It is easy to deduce this assertion from a consideration of the theory.’

The assertion may be true in the case of Bell telephones, which are worked by extremely weak currents, but when these currents are relatively strong, all electro-magnets will reproduce speech perfectly, and we have seen that M. Ader made a telephone with the ordinary electro-magnet which acted perfectly.

The action of the currents sent through the helix of a telephone can be easily explained. Whatever may be the magnetic conditions of the bar, the induced currents of different intensity which act upon it produce modifications in its magnetic state, and hence the molecular vibrations follow from contraction and expansion. These vibrations are likewise produced in the armature under the influence of the magnetisations and demagnetisations which are produced by the magnetic action of the core, and they contribute to the vibrations of the core itself, while at the same time the modifications in the magnetic condition of the system are increased by the reaction of the two magnetic parts upon each other.

When the bar is made of soft iron, the induced currents act by creating magnetisations of greater or less energy, followed by demagnetisations which are the more prompt since inverse currents always succeed to those which have been active, and this causes the alternations of magnetisation and demagnetisation to be more distinct and rapid. When the bar is magnetised, the action is differential, and may be exerted in either direction, according as the induced currents corresponding to the vibrations which are effected pass through the receiving coil in the same or opposite direction as the magnetic current of the bar. If these currents are in the same direction, the action is strengthening, and the modifications are effected as if a magnetisation had taken place. If these currents are of opposite direction, the inverse effect is produced; but, whatever the effects may be, the molecular vibrations maintain the same reciprocal relations and the same height in the scale of musical sounds. If the question is considered from the mathematical point of view, we find the presence of a constant, corresponding with the intensity of the current, which does

not exist in mechanical vibrations, and which may possibly be the cause of the peculiar tone of speech reproduced by the telephone, a tone which has been compared to the voice of Punch. M. Dubois Raymond has published an interesting paper on this theory, which appeared in 'Les Mondes,' February 21, 1878, but we do not reproduce it here, since his remarks are too scientific for the readers for whom this work is intended. We will only add that Mr. C. W. Cunningham asserts that the vibrations produced in a telephone cannot be manifested under precisely the same conditions as those which affect the tympanum of the ear, because the latter has a peculiar funnel-shaped form, which excludes every fundamental note, specially adapted to it, and this is not the case with the bars and magnetic plates which possess fundamental notes capable of greatly altering the half-tones of the voice. He considers the alteration of the voice observed in the telephone must be ascribed to these fundamental notes.

M. Wiesendanger's Thermophone.--M. Wiesendanger, in an article inserted in the 'English Mechanic and World of Science,' September 13, 1878, ascribes the reproduction of speech in certain telephones to vibratory movements resulting from molecular expansions and contractions produced by variations of temperature, and these variations would follow from the currents of varying intensity which are transmitted through the telephonic circuits. He was conscious of one objection to this theory, namely, that the movements of expansion and contraction due to heat are slowly produced, and consequently are not capable of substantial action, rapid enough to produce vibrations; but he considers that molecular effects need not take place under the same conditions as those which are displayed in the case of material substances.

M. Wiesendanger believes that this hypothesis will explain the reproduction of speech in the receiving microphones of Mr. Hughes, and that it may even be applied to the theory of the electro-magnetic telephone, if we consider that a magnetising helix, as well as a magnetic core, round which an electric current circulates, is more or less heated, according to the intensity of the current which traverses it, especially when the wire of the helix and the core are bad conductors of electricity and of magnetism. Pursuing this idea, M. Wiesendanger has sought to construct telephones in which calorific effects are more fully developed, and with this object he used very fine wire of German silver and platinum to make the coils. He ascertained that these coils could produce sounds themselves, and, to increase their intensity, he put them between disks of iron, or on tin tubes, placed on resonant surfaces close to the disks. In this way he says that he was able to make a good receiving telephone without employing magnets. He afterwards arranged the instrument in different ways, of which the two following are the most noteworthy.

In the first, the electro-magnetic system was simply formed by a magnetic disk with a helix wound round it, of which the wire was in connection with the circuit of a microphone, and which was fastened to the centre of the parchment membrane of an ordinary string telephone; the disk consisted of two iron plates separated by a carbon disk of smaller diameter, and the whole was so compressed as to form a solid mass.

In the second, the helix was wound on a tin tube, six inches long and five-eighths of an inch in diameter, which was soldered by merely a point to the centre of the diaphragm of an ordinary telephone.

The inventor asserts that the tube and diaphragm only act as resonators, and that the sounds produced by this instrument are nearly the same as those obtained from the ordinary string telephone: the tunes of a musical box were heard, and the reproduction of speech was perfect, both in intensity and in distinctness of sound; it even appeared that telephonic sounds were audible with the tin tube alone, surrounded by the helix. M. Wiesendanger says that 'these different receiving telephones show clearly that the diaphragm and magnet are not essential, but merely accessory, parts of a telephone.'

VARIOUS EXPERIMENTS MADE WITH THE TELEPHONE.

We must now consider a series of experiments which demonstrate the wonderful properties of the telephone, and which may also give some indication of the importance of the influences by which it is liable to be affected.

Experiments by M. d'Arsonval.--We have seen that the telephone is an extremely sensitive instrument, but its sensitiveness could scarcely be appreciated by ordinary means. In order to gauge it, M. d'Arsonval has compared it to the nerve of a frog, which has hitherto been regarded as the most perfect of all galvanoscopes, and it appears from his experiments that the sensitiveness of the telephone is two hundred times greater than that of the frog's nerve. M. d'Arsonval has given the following account of his researches in the records of the Académie des Sciences, April 1, 1878:

'I prepared a frog in Galvani's manner. I took Siemens' instrument of induction, used in physiology under the name of the chariot instrument. I excited with the ordinary pincers the sciatic nerve, and I withdrew the induced coil until the nerve no longer responded

to the electric excitement. I then substituted the telephone for the nerve, and the induced current, which had ceased to excite the latter, made the instrument vibrate strongly. I withdrew the induced coil, and the telephone continued to vibrate.

‘In the stillness of night I could hear the vibration of the telephone when the induced coil was at a distance fifteen times greater than the minimum at which the excitement of the nerve took place; consequently, if the same law of inverse squares applies to induction and to distance, it is evident that the sensitiveness of the telephone is two hundred times greater than that of the nerve.

‘The sensitiveness of the telephone is indeed exquisite. We see how much it exceeds that of the galvanoscopic frog’s leg, and I have thought of employing it as a galvanoscope. It is very difficult to study the muscular and nervous currents with a galvanometer of 30,000 turns, because the instrument is deficient in instantaneous action, and the needle, on account of its inertia, cannot display the rapid succession of electric variations, such as are effected, for example, in a muscle thrown into electric convulsion. The telephone is free from this inconvenience, and it responds by vibration to each electric change, however rapid it may be. The instrument is therefore well adapted for the study of electric tetanus in the muscle. It is certain that the muscular current will excite the telephone, since this current excites the nerve, which is less sensitive than the telephone. But for this purpose some special arrangement of the instrument is required.

‘It is true that the telephone can only reveal the variations of an electric current, however faint they may be; but I have been able, by the use of a very simple expedient, to reveal by its means the presence of a continuous current, also of extreme faintness. I send the current in question into the telephone, and, to obtain its variations, I break this current mechanically with a tuning-fork. If no current is traversing the telephone, it remains silent. If, on the other hand, the faintest current exists, the telephone vibrates in unison with the tuning-fork.’

Professor Eick, of Wurzburg, has also used the telephone for physiological researches, but in a direction precisely opposite to that explored by M. d’Arsonval. He ascertained that when the nerves of a frog were placed in connection with a telephone, they were forcibly contracted when anyone was speaking into the instrument, and the force of the contractions chiefly depended on the words pronounced. For instance, the vowels _a_, _e_, _i_ produced hardly any effect, while _o_ and especially _u_ caused a very strong contraction. The words _Liege still_, pronounced in a loud voice, only produced a faint movement, while the word _Tucker_, even when spoken in a low voice, strongly agitated the frog. These experiments, reminding us of those by Galvani, were necessarily based on the effects produced by the induced currents developed in the telephone, and they show that if this instrument is a more sensitive galvanoscope than the nerve of a frog, the latter is more susceptible than the most perfect galvanometer.

Experiments by M. Demoget.--In order that he might compare the intensity of the sounds transmitted by the telephone with the intensity of original sounds, M. Demoget placed two telephones in an open space. He held the first to his ear, while his assistant withdrew to a distance, constantly repeating the same syllable with the same intensity of tone in the second instrument. He first heard the sound transmitted by the telephone, and then the sound which reached him directly, so that comparison was easy, and he obtained the following results.

At a distance of 93 yards the original and the transmitted sounds were received with equal intensity, while the vibrating disk was about 5 centimètres from the ear. At this moment, therefore, the relative intensity was as 25 to 81,000,000. In other words, the sound transmitted by the telephone was only 1/3000000 of the emitted sound. ‘But,’ said M. Demoget, ‘since the stations at which we worked could not be regarded as two points freely vibrating in space, the ratio may be reduced by one half on account of the influence of the earth, and the sound transmitted by the telephone may be supposed to be 1,500,000 times weaker than that emitted by the voice.

‘Again, since we know that the intensity of the two sounds is in proportion to the square of the range of vibrations, it may be concluded that the vibrations of the two telephone disks were in direct proportion to the distance, that is, as 5 to 9,000, or that the vibrations of the sending telephone were eighteen hundred times greater than those of the receiving telephone. These latter may therefore be compared to molecular vibrations, since the range of those of the sending telephone was extremely small.

‘Without in any degree detracting from the merit of Bell’s remarkable invention,’ continues M. Demoget, ‘it follows from what I have said above that the telephone, considered as a sending instrument, leaves much to be desired, since it only transmits the 18/100 part of the original power; and if it has produced such unexpected results, this is due to the perfection of the organ of hearing, rather than to the perfection of the instrument itself.’

M. Demoget considers this loss of power which takes place in the telephone to be chiefly owing to the eight transformations in succession to which sound is subjected before reaching the ear, setting aside the loss due to the electric resistance of the line, which might in itself suffice to absorb the whole force.

In order to estimate the force of the induced currents which act upon a telephone, M. Demoget has attempted to compare them with currents of which the intensity is known, and which produce vibrations of like nature and force: for this purpose he has made use of two telephones, A and B, communicating through a line 22 yards in length. He placed a small file in slight contact with the vibrating disk of the telephone A, and caused friction between the file and a metallic plate: the sound thus produced was necessarily transmitted by the telephone B, with an intensity which could be estimated. He then substituted a battery for the telephone A, and the file was introduced into the circuit by connecting it with one of the poles. The current could only be closed by the friction of the file with the plate, which had a spring, and was in communication with the other end of the circuit. In this way broken currents were obtained, which caused vibration in the telephone B, and produced a sound of which the intensity varied with the strength of the battery current. In this way M. Demoget endeavoured to find the electric intensity capable of producing a sound similar to that of the telephone A, and he ascertained that it corresponded in intensity to that produced in a small thermo-electric battery formed of an iron and a copper wire, two millimètres in diameter, flattened at the end, and soldered to the tin: the faint current produced by this battery only caused a short wire galvanometer to deviate two degrees.

This estimate does not appear to us to unite so many conditions of accuracy as to enable us to deduce from it the degree of sensitiveness possessed by a telephone, a sensitiveness which the experiments of Messrs. Warren de la Rue, Brough, and Peirce show to be much greater. Mr. Warren de la Rue, as we have seen, used Thomson's galvanometer, and compared the deviation produced on the scale of this galvanometer with that caused by a Daniell cell traversing a circle completed by a rheostat: he ascertained that the currents discharged by an ordinary Bell telephone are equivalent to those of a Daniell cell traversing 100 megohms of resistance, that is, 6,200,000 miles of telegraphic wire. Mr. Brough, the Director of Indian Telegraphs, considers that the strongest current which at any given moment causes a Bell telephone to work does not exceed 1/1000000 of the unit of current, that is, one Weber, and the current transmitted to the stations on the Indian telegraphic line is 400,000 times as strong. Finally, Professor Peirce, of Boston, compares the effects of the telephonic current with those which would be produced by an electric source of which the electro-motive force should be 1/200000 part of a volt, or one Daniell cell. Mr. Peirce justly remarks that it is difficult to estimate the real value of these kinds of currents at any precise sum, since it essentially varies according to the intensity of the sounds produced on the transmitting telephone; but it may be affirmed that it is less than the 1/1000000 part of the current usually employed to work the instruments on telegraphic lines.

Signor Galileo Ferraris, who has recently published an interesting treatise on this question in the 'Atti della Reale Accademia delle Scienze di Torino' (June 13, 1878), states that the intensity of the currents produced by the ordinary Bell telephone varies with the pitch of the sound emitted.

Experiments by M. Hellesen, of Copenhagen.--In order to estimate the reciprocal effects of different parts of a telephone, M. Hellesen has made telephones of the same size with three different arrangements which act inversely to each other. The first was of the ordinary form, the second like that of Bell's first system, that is, with a membrane supporting a small iron armature on its centre, instead of a vibrating disk, and the third telephone consisted of a hollow cylindrical magnet, with the vibrating disk fixed to one of its poles, and the disk was adapted to move before a flat, snail-shaped spiral, of which the number of spirals equalled those of the two other helices. In this last arrangement, the induced currents resulting from the vibrations of the voice might be assimilated to those which follow from the approximation and withdrawal of the two parallel spirals, one of which should be traversed by a current. It is this last arrangement which Mr. Bell has adopted as producing the best effects, and it is rare in the history of discoveries that an inventor hits at once on the best arrangement of his instrument.

Experiments by M. Zetsche.--There are always a few perverse minds, impelled by a spirit of contradiction to deny evidence, and thus they attempt to depreciate a discovery of which the glory irritates them. The telephone and the phonograph have been the objects of such unworthy criticism. It has been said that electric action had nothing to do with the effects produced in the telephone, and that it only acted under the influence of mechanical vibrations transmitted by the conducting wire, just as in a string telephone. It was in vain to demonstrate to these obstinate minds that no sound is produced when the circuit is broken, and in order to convince them M. Zetsche has made some experiments to show, from the mode in which sound is propagated, that it is absurd to ascribe the sound produced in a telephone to mechanical vibration. He wrote to this effect in an article inserted in the 'Journal Télégraphique,' Berne, January 25, 1878:

‘The correspondence by telephone between Leipzig and Dresden affords another proof that the sounds which reproduce words at the receiving station are due to electric currents, and not to mechanical vibrations. The velocity with which sound is transmitted by vibrations on the wire, in the case of longitudinal undulations, may be estimated at three miles one furlong a second, so that the sound ought to traverse the distance from Leipzig to Dresden in 25 seconds. The same time ought to elapse before receiving the answer. Consequently there should be an interval of more than three-quarters of a minute allowed for each exchange of communication, which is by no means the case.’

Experiments which may be made by anyone.--We will conclude this chapter, devoted to the account of the different experiments made with the telephone, by the mention of a singular experiment, which, although easily performed, has only been suggested a few months ago by a Pennsylvanian newspaper. It consists in the transmission of speech by a telephone simply laid on some part of the human body adjacent to the chest. It has been asserted that any part of the body will produce this effect, but according to my experience, I could only succeed when the telephone was firmly applied to my chest. Under such conditions, and even through my clothes, I could make myself heard when speaking in a very loud voice, from which it appears that the whole of the human body takes part in the vibrations produced by the voice. In this case, the vibrations are mechanically transmitted to the diaphragm of the sending telephone, not by the air, but by the body itself acting on the outside of the telephone.

THE MICROPHONE.

The microphone is in fact only the sender of a battery telephone, but with such distinctive characteristics that it may be regarded as an original invention which is entitled to a special name. The invention has lately given rise to an unfortunate controversy between its inventor, Mr. Hughes, and Mr. Edison, the inventor of the carbon telephone and the phonograph--a controversy which has been embittered by the newspapers, and for which there were no grounds. For although the scientific principle of the microphone may appear to be the same as that of Mr. Edison’s carbon sender, its arrangement is totally different, its mode of action is not the same, and the effect required of it is of quite another kind. Less than this is needed to constitute a new invention. Besides, a thorough examination of the very principle of the instrument must make us wonder at Mr. Edison’s claim to priority. He cannot in fact regard as his exclusive possession the discovery of the property possessed by some substances of moderate conductivity of having this power modified by pressure. In 1856, and often subsequently, as for example in 1864, 1872, 1874, and 1875, I made numerous experiments on this point, which are described in the first volume of the second edition of my ‘Exposé des applications de l’Electricité,’ and also in several papers presented to the Académie des Sciences, and inserted in their _Comptes rendus_. M. Clarac again, in 1865, employed a tube made of plumbago, and provided with a moveable electrode, to produce variable resistances in a telegraphic circuit. Besides, in Mr. Edison’s telephonic sender, the carbon disk, as we have seen, must be subjected to a certain initial pressure, in order that the current may not be broken by the vibrations of the plate on which it rests, and consequently the modifications of resistance in the circuit which produce articulate sounds are only caused by greater or less increase and diminution of pressure, that is, by differential actions. We shall presently see that this is not the case with the microphone. In the first place, the carbon contact is effected in the latter instrument on other carbons and not with platinum disks, and these contacts are multiple. In the second place, the pressure exerted on all the points of contact is excessively slight, so that the resistances can be varied in an infinitely greater ratio than in Mr. Edison’s system; and for this very reason it is possible to magnify the sounds. In the third place, a microphone can be made of other substances besides carbon. Finally, no vibrating disk is needed to make the microphone act; the simple medium of air is enough, so that it is possible to work the instrument from some little distance.

We do not therefore see the grounds for Mr. Edison’s assertions, and especially for the way in which he has spoken of Messrs. Hughes and Preece, who are well known in science and are in all respects honourable men. I repeat my regret that Mr. Edison should have made this ill-judged attack on them, since it must injure himself, and is unworthy of an inventor of such distinction. If we look at the question from another point of view, we must ask Mr. Edison why, if he invented the microphone, he did not make us acquainted with its properties and results. These results are indeed startling, since the microphone has in so short a time attracted general attention; and it is evident that the clear-sighted genius of this celebrated American inventor would have made the most of the discovery if it were really his. The only justification for Mr. Edison’s claim consists in his ignorance of the purely scientific discoveries made in Europe, so that he supposed the invention of the microphone to be wholly involved in the principle which he regards as his peculiar discovery.

In Mr. Hughes’s instrument which we are now considering, the sounds, instead of reaching the receiving stations much diminished, which is the case with ordinary telephones, and even with that of Mr. Edison, are often remarkably increased, and it is for this

reason that Mr. Hughes has given to this telephonic system the name of Microphone, since it can be employed to discover very faint sounds. Yet we must add that this increase really takes place only when the sounds result from mechanical vibrations transmitted by solid substances to the sending instrument. The sounds propagated through the air are undoubtedly a little more intense than in the ordinary system, but they lose some of their force, and therefore it cannot be said that in this case the microphone has the same effect upon sounds as the microscope has on objects on which light is thrown. It is true that with this system it is possible to speak at a distance from the instrument, and I have even been able to transmit conversation in a loud voice, when standing at a distance of nine yards from the microphone. When close to the instrument, I was also perfectly able to make myself heard at the receiving station while speaking in a low voice, and even to send the sounds to a distance of ten or fifteen centimètres from the mouthpiece of the receiving telephone by raising the voice a little; but the increase of sound is not really very evident unless it is produced by a mechanical action transmitted to the standard of the instrument.

Thus the steps of a fly walking on the stand are clearly heard, and give the sensation of a horse's tread; and even a fly's scream, especially at the moment of death, is said by Mr. Hughes to be audible. The rustling of a feather or of a piece of stuff on the board of the instrument, sounds completely inaudible in ordinary circumstances, are distinctly heard in the microphone. It is the same with the ticking of a watch placed upon the stand, which may be heard at ten or fifteen centimètres from the receiver. A small musical box placed upon the instrument gives out so much sound, in consequence of its vibratory movements, that it is impossible to distinguish the notes, and in order to do so it is necessary to place the box close to the instrument, without allowing it to come in contact with any of its constituent parts. It therefore appears that the instrument is affected by the vibrations of air, and the transmitted sounds are fainter than those heard close to the box. On the other hand, the vibrations produced by the pendulum of a clock, when placed in communication with the standard of the instrument by means of a metallic rod, are heard perfectly, and may even be distinguished when the connection is made by the intervention of a copper wire. A current of air projected on the system gives the sensation of a trickle of water heard in the distance. Finally, the rumbling of a carriage outside the house is transformed into a very intense crackling noise, which may combine with the ticking of a watch, and will often overpower it.

Different Systems of Microphones.--The microphone has been made in several ways, but the one represented in fig. 39 is the arrangement which renders it the most sensitive. In this system, two small carbon cubes, A, B, are placed one above the other on a vertical wooden prism; two holes are pierced in the cubes to serve as sockets for a spindle-shaped carbon pencil, that is, with the points fined off at the two ends, and about four centimètres long: if of a large size, the inertia will be too great. One end of this pencil is in the cavity of the lower carbon, and the other must move freely in the upper cavity which maintains it in a position approaching to that of instable equilibrium, that is, in a vertical position. Mr. Hughes states that the carbons become more effective if they are steeped in a bath of mercury at red heat, but they will act well without undergoing this process. The two carbon cubes are also provided with metallic contacts which admit of their being placed in connection with the circuit of an ordinary telephone in which a Leclanché battery has been placed, or one, two, or three Daniell cells, with an additional resistance introduced into the circuit.

[Illustration: FIG. 39.]

In order to use this instrument, it is placed on a table, with the board which serves to support it, taking care to deaden any extraneous vibrations by interposing between this board and the table several folds of stuff so arranged as to form a cushion, or, which is better, a belt of wadding, or two caoutchouc tubes: what is said by a person standing before this system is immediately reproduced in the telephone, and if a watch is placed on the stand, or a box with a fly enclosed in it, all its movements are heard. The instrument is so sensitive that words said in a low voice are most easily heard, and it is possible, as I have already said, to hear the speaker when he is standing nine yards from the microphone. Yet some precautions are necessary in order to obtain good results with this system, and besides the cushions placed beneath the instrument to guard it from the extraneous vibrations which might ensue from any movements communicated to the table, it is also necessary to regulate the position of the carbon pencil. It must always rest on some point of the rim of the upper cavity; but as the contact may be more or less satisfactory, experience alone will show when it is in the best position, and it is a good plan to make use of a watch to ascertain this. The ear is then applied to the telephone, and the pencil is placed in different positions until the maximum effect is obtained. To avoid the necessity of regulating the instrument in this way, which must be done repeatedly by this arrangement, MM. Chardin and Berjot, who are ingenious in the construction of telephones on this pattern, have added to it a small spring-plate, of which the pressure can be regulated, and which rests against the carbon pencil itself. This system works well.

[Illustration: FIG. 40.]

M. Gaiffe, by constructing it like a scientific instrument, has given the instrument a more elegant form. Fig. 40 represents one of his two models. In this case, the cubes or carbon dice are supported by metallic holders, and the upper one E is made to move up and down a copper column G, so as to be placed in the right position by tightening the screw V. In this way the carbon pencil can be made to incline more or less, and its pressure on the upper carbon can be altered at pleasure. When the pencil is in a vertical position, the instrument transmits articulate sounds with difficulty, on account of the instability of the points of contact, and rustling sounds are heard. When the inclination of the pencil is too great, the sounds are purer and more distinct, but the instrument is less sensitive. The exact degree of inclination should be ascertained, which is easily done by experiment. In another model M. Gaiffe substitutes for the carbon pencil a very thin square plate of the same material, bevelled on its lower and upper surfaces, and revolving in a groove cut in the lower carbon. This plate must be only slightly inclined in order to touch the upper carbon, and under these conditions it transmits speech more loudly and distinctly.

I must also mention another arrangement, devised by Captain Carette of the French Engineers, which is very successful in transmitting inarticulate sounds. In this case the vertical carbon is pear-shaped, and its larger end rests in a hole made in the lower carbon; its upper and pointed end goes into a small hole made in the upper carbon, but so as hardly to touch it, and there is a screw to regulate the distance between the two carbons. Under such conditions, the contacts are so unstable that almost anything will put an end to them, and consequently the variations in the intensity of the transmitted current are so strong that the sounds produced by the telephone may be heard at the distance of several yards.

[Illustration: FIG. 41.]

Fig. 41 represents another arrangement, devised by M. Ducretet. The two carbon blocks are at D D′, the moveable carbon pencil is at C, the telephone at T, and the binding screws at B B′. An enlarged figure of the arrangement of the carbons is given on the left. The arm which holds the upper carbon D is fastened to a rod, bearing a plate P′, of which the surface is rough, and a little cage C′, made of wire netting, can be placed upon the plate, so as to enable us to study the movements of living insects.

When speech is to be transmitted with a force which can make the telephone audible in a large room, the microphone must have a special arrangement, and fig. 42 represents the one which Mr. Hughes considers the most successful, to which he has given the name of _speaker_.

[Illustration: FIG. 42.]

In this new form, the moveable carbon which is required to produce the variable contacts is at C, at the end of a horizontal bar B A, properly balanced so as to move up and down on its central point. The support on which the bar oscillates is fastened to the end of a spring plate in order that it may vibrate more easily, and the lower carbon is placed at D below the first. It consists of two pieces laid upon each other, so as to increase the sensitiveness of the instrument, and we represent the upper piece at E, which is raised so as to show that when it is desired only one of these carbons need be used. For this purpose the carbon E is fastened to a morsel of paper, which is fixed to the little board and contributes to the articulation. A spring R, of which the tension can be regulated by the screw _t_, serves to regulate the pressure of the two carbons. Mr. Hughes recommends the use of metallised charcoal prepared from deal.[14] The whole is then enclosed in a semi-cylindrical case H I G, made of very thin pieces of deal, and the system is fixed, together with another similar system, in a flat box, M J L I, which, on the side M I, presents an opening before which the speaker stands, taking care to keep his lower lip at a distance of two centimètres from the bottom of the box. If the two telephones are connected for strength, and if the battery employed consists of two cells of bichromate of potash, it is possible to act so strongly on the current, that, after traversing an induction coil only six centimètres long, a telephone of Bell’s square model can be made to speak, so as to be heard from all parts of a room; a speaking tube, about a yard long, must indeed be applied to it. Mr. Hughes asserts that the sounds produced by it are nearly as loud as those of the phonograph, and this is confirmed by Mr. Thomson.

M. Boudet de Paris has lately invented a microphone speaker of the same kind, with which it is possible to make a small telephone utter a loud sound. An induction coil, influenced by a single Leclanché cell, must be employed.

Suppose that a very small carbon rod with pointed ends is placed at the bottom of a box, of about the size of a watch. One end of the rod rests against a morsel of carbon, which is fastened to a very thin steel diaphragm, placed before a mouthpiece which acts as a lid to the box, and is screwed above it. Next suppose that a small piece of paper, folded in two, in the shape of the letter V, is fixed above that part of the carbon in contact with the carbon of the diaphragm. This constitutes the instrument, and in order to work it, it must be held in a vertical position before the mouth, at a distance of about three centimètres, and it is necessary to speak in the ordinary tone. If the telephone is placed in direct communication with this instrument, it will send the voice to a distance. Without

employing a Leclanché cell, the voice may be heard at the distance of ten yards, if one of the carbons used for the phonograph is placed before the mouthpiece of the telephone.

In this system, the sensitiveness of the instrument is entirely due to the slightness of the contact between the two carbons, and the slight elasticity of the folded paper constitutes the contact. Perhaps the paper itself has some influence; at any rate the most delicate spiral spring is incapable of producing the same effect, and it is necessary to suspend the instrument vertically, in order that the weight of the moveable carbon may not affect it. It can be regulated by depressing or elevating that part of the paper which rests on the carbon rod.

Although it is possible to work all telephones with this instrument, some are more effective than others. The mouthpiece must be concave, and the diaphragm must be close to its rim, and must be made of a particular kind of tin. The ordinary diaphragm does not act well, and M. Boudet de Paris has tried several, so as to obtain the maximum effect.

It is certain that when the instruments are as well regulated as those which the inventor has deposited with me, their results are really surprising. It is even possible, by using several microphones at the sending station, to obtain the reproduction of duets, and even of trios, with remarkable effect.

With this kind of microphone speaker M. Boudet de Paris is able to transmit speech into a snuff-box telephone, merely consisting of a flat helix of wire, placed before a slightly magnetised steel plate, and without insertion of a magnetic core. A single Leclanché cell was enough. An experiment of the same nature was tried in England, but it was found necessary to use six Leclanché cells.

[Illustration: FIG. 43]

[Illustration: FIG. 44.]

The microphone may also be made of morsels of carbon pressed into a box between two metallic electrodes, or enclosed in a tube with two electrodes represented by two elongated fragments of carbon. In the latter case the carbons ought to be as cylindrical as possible, and those made by M. Carré for the Jablochkoff candles are very suitable. Fig. 43 represents an instrument of this kind which M. Gaiffe arranged for me, and which, as we shall see, serves as a thermoscope (fig. 44). It is composed of a quill filled with morsels of carbon, and those at the two ends are tipped with metal. One of these metal tips ends in a large-headed screw which, by means of its supports A B, is able to press more or less on the morsels of carbon in the tube, and consequently to establish a more or less intimate contact between them. When the instrument is properly regulated, speech can be reproduced by speaking above the tube. It is therefore a microphone as well as a thermoscope. Mr. Hughes has remarked one curious fact, namely, that if the different letters of the alphabet are pronounced separately before this sort of microphone, some of them are much more distinctly heard than others, and it is precisely those which correspond to the breathings of the voice.

A microphone of this kind may be made by substituting for the carbon powders of more or less conductivity, or even metal filings. I have shown in my paper on the action of substances of moderate conductivity, that such power varies considerably with the pressure and the temperature; and as the microphone is based on the differences of conducting power which result from differences of pressure, we can understand that these powders may be used as a means of telephonic transmission. In a recent arrangement of this system Mr. Hughes has made the powder adhere together with a sort of gum, and has thus made a cylindrical pencil which, when connected with two electrodes which are good conductors, can produce effects analogous to those we have just described. As I have said, it is possible to use metal filings, but Mr. Hughes prefers powdered charcoal.

Mr. Blyth states that a flat box, about 15 inches by 9, filled with coke, and with two tin electrodes fixed to the two ends, is one of the best arrangements for a microphone. He says that three of these instruments, hung like pictures against the wall of a room, would suffice, when influenced by a single Leclanché cell, to make all the sounds produced in a telephone audible, and especially vocal airs. Mr. Blyth even asserts that a microphone capable of transmitting speech can be made with a simple piece of coke, connected with the circuit by its two ends, but it must be coke: a retort carbon, with electrodes, will not act.

It is a remarkable property of these kinds of microphones that they can act without a battery, at least when they are so arranged as to form a voltaic element for themselves, and this can be done by throwing water on the carbons. Mr. Blyth, who was the first to speak of this system, does not distinctly indicate its arrangement, and we may assume that his instrument did not differ from the one we have already described, to which water must have been added. In this way, indeed, I have been able to transmit not only the ticking of a watch and the sounds of a musical box, but speech itself, which was often more distinctly expressed than in an ordinary microphone, since it was free from the sputtering sound which is apt to accompany the latter. Mr. Blyth also asserts that

sounds may be transmitted without the addition of water, but in this case he considers that the result is due to the moisture of the breath. Certainly much moisture is not required to set a voltaic couple in action, especially when a telephone is the instrument of manifestation. The ordinary microphone may be used without a battery, if the circuit in which it is inserted is in communication with the earth by means of earthen cakes; the currents which then traverse the circuit will suffice to make the tickings of a watch placed upon the microphone perfectly audible. M. Cauderay, of Lausanne, in a paper sent to the Académie des Sciences, July 8, 1878, informs us that he made this experiment on a telegraphic wire which unites the Hôtel des Alpes at Montreux with a _châlet_ on the hill--a distance of about 550 yards.

The Microphone used as a Speaking Instrument.--The microphone can not only transmit speech, but it can also under certain conditions reproduce it, and consequently supply the place of the receiving telephone. This seems difficult to understand, since a cause for the vibratory motion produced in part of the circuit itself can only be sought in the variations in intensity of the current, and the effects of attraction and magnetisation have nothing to do with it. Can the action be referred to the repulsions reciprocally exerted by the contiguous elements of the same current? Or are we to consider it to be of the same nature as that which causes the emission of sounds from a wire when a broken current passes through it, so that an electric current is itself a vibratory current, as Mr. Hughes believes? It is difficult to reply to these questions in the present state of science; we can only state the fact, which has been published by Messrs. Hughes, Blyth, Robert Courtenay, and even by Mr. Edison himself. I have been able to verify the fact myself under the experimental conditions indicated by Mr. Hughes, but I was not so successful in the attempt to repeat Mr. Blyth's experiments. This gentleman stated that in order to hear speech in a microphone it would be enough to use the model made from fragments of carbon, as we have described, to join to it a second microphone of the same kind, and to introduce into the circuit a battery consisting of two Grove elements. If anyone then speaks above the carbons of one of the microphones, what is said should be distinctly heard by the person who puts his ear to the other, and the importance of the sounds thus produced will correspond with the intensity of the electric source employed. As I have said, I was unable by following this method to hear any sound, still less articulate speech; and if other experiments had not convinced me, I should have doubted the correctness of the statement. But this negative experiment does not in fact prove anything, since it is possible that my conditions were wrong, and that the cinders which I employed were not subject to the same conditions as Mr. Blyth's fragments of coke.

[Illustration: FIG. 45.]

With respect to Mr. Hughes's experiments, I have repeated them with the microphone made by MM. Chardin and Berjot, using that by M. Gaiffe as the sender, and I ascertained that with a battery of only four Leclanché cells, a scratch made on the sender, and even the tremulous motion and the airs played in a little musical box placed on the sender, were reproduced--very faintly, it is true--in the second microphone; in order to perceive them, it was enough to apply the ear to the vertical board of the instrument. It is true that speech was not reproduced, but of this Mr. Hughes had warned me; it was evident that with this arrangement the instrument was not sufficiently sensitive.

A different arrangement of the microphone is required for the transmission and the reproduction of speech by this system, and a section of the one which Mr. Hughes found most successful is given in fig. 45. It somewhat resembles Mr. Hughes's microphone speaker, placed in a vertical position, and the fixed carbon is fastened to the centre of the stretched membrane of a string telephone. The ear or mouth tube is at A, the membrane at D D, the carbon just mentioned at C: this carbon is of metallised charcoal prepared from deal, and so also is the double carbon E, which is in contact with it and is fastened to the upper end of the little bar G I. The whole is enclosed in a small box, and the pressure exerted on the contact of the two carbons is regulated by a spring R and a screw H. The tube of the telephone serves as an acoustic tube for the listener, and Mr. Hughes's speaker, described above, acts as sender. It is hardly necessary to say that the two instruments are placed at each end of the circuit, that the carbons are connected with the two poles of a battery of one or two cells of bichromate of potash, or two Bunsen or six Leclanché cells, and the two instruments are connected by the line wire. Under such conditions, conversation may be exchanged, but the sounds are always much less distinct than they are in a telephone.

I was able to ascertain this fact with a roughly made instrument brought from England by Mr. Hughes. MM. Berjot, Chardin, and de Méritens, who were also present at the experiments, were able with me to hear speech perfectly, and I have since successfully repeated the experiment alone, but it does not always succeed, and under its present conditions the instrument has no importance in a scientific point of view. It is evident that the instrument can dispense with any support, and the little box then forms the handle of the instrument; in this case the two binding screws are placed at the end of this handle, as in a telephone. The microphone speaker with a disk, represented in fig. 5, which acts as sender to the singing condenser, can be used, when properly regulated, as

a receiving microphone. M. Berjot has obtained good results from a little instrument of the same kind as that in fig. 45, but with a metal diaphragm, and the microphonic system consists of a cylindrical piece of carbon resting on a small disk of the same substance, which is galvanised and soldered to the diaphragm. The whole is enclosed in a small round box, with its upper part cut in the form of a mouthpiece.

It seems that all microphone senders with disks can reproduce speech more or less perfectly; it is a question of adjusting and refining the carbon points of contact. A weak battery, consisting of a single Leclanché cell, is better for these instruments than a strong battery, precisely because of the effects of oxidation and polarisation, which are so energetically produced at these points of contact when the battery is strong.

The effects of the microphone receiver explain the sounds, often very intense, produced by the Jablochkoff candles when they are influenced by electro-magnetic machines. These sounds always vibrate in unison with those emitted by the machine itself, and they result, as I have already shown, from the rapid magnetisations and demagnetisations which are effected by the machine. These effects, observed by M. Marcel Deprez, were particularly marked in M. de Méritens' first machines.

Other Arrangements of Microphones.--An arrangement such as we have just described has been employed by M. Carette to form an extremely powerful microphone speaker. The only difference is that the stretched membrane is replaced by a thin metallic disk: he fastens one of the carbons to the centre of this disk, and applies to it the other carbon, which is pointed, and held by a _porte-carbon_ with a regulating screw, so that the pressure which takes place between the two carbons may be regulated at pleasure. By this arrangement speech may be heard at a distance from the telephone. In other respects it resembles the telephone sender represented in fig. 5.

M. de Méritens has executed the system represented, fig. 45, on a large scale, forming the tube A B of a zinc funnel a yard in length, and in this way he has been able to magnify the sounds, so that a conversation held in a low voice, three or four yards from the instrument, has been produced in a telephone with more sonorous distinctness. The instrument was placed on the floor of the apartment, with the opening of the funnel above, and the telephone was in the cellars of the house.

The form of the microphone has been varied in a thousand ways, to suit the purposes to which it was to be applied. In the 'English Mechanic and World of Science,' June 28, 1878, we see the drawings of several arrangements, one of which is specially adapted for hearing the steps of a fly. It is a box, with a sheet of straw paper stretched on its upper part; two carbons, separated by a morsel of wood, and connected with the two circuit wires, are fastened to it, and a carbon pencil, placed crosswise between the two, is kept in this position by a groove made in the latter. A very weak battery will be enough to set the instrument at work, and when the fly walks over the sheet of paper it produces vibrations strong enough to react energetically on an ordinary telephone. The instrument must be covered with a glass globe. When a watch is placed on the membrane, with its handle applied to the morsel of wood which divides the two carbons, the noise of its ticking may be heard through a whole room. Two carbon cubes placed side by side, and only divided by a playing-card, may also be used instead of the arrangement of carbons described above. A semicircular cavity, made in the upper part of the two carbons, in which are placed some little carbon balls, smaller than a pea and larger than a mustard seed, will make it possible to obtain multiple contacts which are very mobile and peculiarly fit for telephonic transmissions. This arrangement has been made by Mr. T. Cuttriss.

Several other arrangements of microphones have been devised by different makers and inventors, such as those of Messrs. Varey, Trouvé, Vereker, de Combettes, Loiseau, Lippens, de Courtois, Pollard, Voisin, Dumont, Jackson, Paterson, Taylor, &c., and they are more or less satisfactory. The instruments of MM. Varey, Trouvé, Lippens, and de Courtois are the most interesting, and we will describe them.

M. Varey's microphone consists of a sounding box of deal, mounted in a vertical position on a stand, and two microphones are arranged on either side of it, with vertical carbons united for tension. A small Gaiffe cell of chloride of silver, without liquid, is applied to the standard of the instrument, and is enough to make it work perfectly. This system is extremely sensitive.

M. Trouvé's microphones, represented in figs. 46, 47, 48, are extremely simple, so that he is able to sell them at a very moderate price. They generally consist of a small vertical cylindrical box, as we see in the figure, with disks of carbon at its two ends, which are united by a carbon rod, or by a metallic tube tipped with carbon. This rod or tube turns freely in two cavities made in the carbons, and the box, while acting as a sounding box, becomes at the same time a prison for the insects whose movements and noises are the objects of study.

[Illustration: FIG. 46.]

These boxes may be suspended on a cross-bar (fig. 47) by the two communicating wires, so as to be completely insulated. In this case the ticking of a watch placed upon the board, friction, and external shocks are hardly heard, but on the other hand the sound vibrations of the air alone are transmitted, and they acquire great distinctness. We have often repeated these experiments, and have always found that the tones of the voice were perfectly preserved.

The model represented fig. 48 is still more simple, and appears to be the latest development of this kind of instrument. It consists of a stand and a disk united by a central rod. The upper disk moves round the central rod, and permits the vertical carbon to assume any inclination which is desired. It is evident that the instrument will become less sensitive when the carbon is more oblique.

[Illustration: FIG. 47.]

We must also mention a very successful microphone devised by M. Lippens. It is a slightly made box, like that of M. Varey, and on its opposite faces there are applied, on two frames left empty for the purpose, two thin plates of hardened caoutchouc, in the centre of which inside the box, two carbons are fastened, and on their outer surface a half-sphere is hollowed.

[Illustration: FIG. 48.]

The interval between the two carbons hardly amounts to two millimètres, and a carbon ball is inserted into the two cavities which form its spherical case. This ball is supported by a spiral spring which can be extended more or less by means of a wire wound on a windlass which is fixed above the instrument, like the spring of an electric telegraph instrument. By means of this spring, the pressure of the carbon ball against the sides of the cavity which contains it can be regulated at pleasure, and the sensitiveness of the instrument and its capacity for transmitting speech can be adjusted. Under these conditions, the vibrations of the caoutchouc plates directly affect the microphone, and the currents of air have no influence on it, so that the effects are more distinct. It is so sensitive that it is best for the speaker to place himself at the distance of at least 50 centimètres from the instrument. M. Lippens' instrument is a pretty one, mounted on a wooden stand, which is neatly turned.

In order to put an end to the sputtering usual in microphones, it occurred to M. de Courtois to prevent any cessation of contact between the carbons by keeping them close together, and to effect the variations of resistance necessary for articulate sounds by making them slide over each other, so as to insert a shorter or longer portion of the carbon in the circuit. For this purpose a vibrating disk is placed in a vertical position in a rigid frame, and a small conducting rod, terminated by a pointed carbon, is applied to it, with this carbon point resting on another flat piece of carbon placed below it. Influenced by the vibrations of the disk, the carbon point moves to and fro, effecting more or less extensive contacts with the lower carbon, and thus producing variations of resistance which almost correspond to the range of vibrations on the disk.

Experiments made with the Microphone.--I must now mention the interesting experiments which led Mr. Hughes to the invention of the remarkable instrument of which we have spoken, as well as those undertaken by other scientific men, either from a scientific or a practical point of view.

Believing that light and heat can modify the conductivity of bodies, Mr. Hughes went on to consider whether sound vibrations, transmitted to a conductor traversed by a current, would not also modify this conductivity by provoking the contraction and expansion of the conducting molecules, which would be equivalent to the shortening or lengthening of the conductor thus affected. If such a property existed, it would make it possible to transmit sounds to a distance, since variations in the conductivity would result from variations corresponding to the intensity of the current acting on the telephone. The experiment which he made on a stretched metal wire did not, however, fulfil his expectation, and it was only when the wire vibrated so strongly as to break, that he heard a sound at the moment of its fracture. When he again joined the two ends of the wire, another sound was produced, and he soon perceived that imperfect contact between the two broken ends of wire would enable him to obtain a sound. Mr. Hughes was then convinced that the effects he wished to produce could only be obtained with a divided conductor, and by means of imperfect contacts.

He then sought to discover the degree of pressure which it was most expedient to exert between the two adjacent ends of the wire, and for this purpose he effected the pressure by means of weights. He ascertained that when the pressure did not exceed the weight of an ounce on the square inch at the point of connection, the sounds were reproduced with distinctness, but somewhat imperfectly. He next modified the conditions of the experiment, and satisfied himself that it was unnecessary to join the wires end to end in order to obtain this result. They might be placed side by side on a board, or even separated (with a conductor placed

crosswise between them), provided that the conductors were of iron, and that they were kept in metallic connection by a slight and constant pressure. The experiment was made with three Paris points, and arranged as it appears in fig. 49, and it has since been repeated under very favourable conditions by Mr. Willoughby Smith with three of the so-called rat-tail files, which made it possible to transmit even the faint sound of the act of respiration.[15]

[Illustration: FIG. 49.]

He afterwards tried different combinations of the same nature, which offered several solutions of continuity, and a steel chain produced fairly good results, but slight inflections, like those caused by the _timbre_ of the voice, were not reproduced, and he tried other arrangements. He first sought to apply metallic powders to the points of contact; powdered zinc and tin, known in commerce under the name of white bronze, greatly increased the effects obtained; but they were unstable, on account of the oxidation of the contacts; and it was in seeking to solve this difficulty, as well as to discover the most simple means of obtaining a slight and constant pressure on the contacts, that Mr. Hughes was led to the arrangement, previously described, of carbons impregnated with mercury, and he thus obtained the maximum effect.[16]

Mr. Hughes considers that the successful effects of the microphone depend on the number and perfection of the contacts, and this is doubtless the reason why some arrangements of the carbon pencil in the instrument described above were more favourable than others.

In order to reconcile these experiments with his preconceived ideas, Mr. Hughes thought that, since the differences of resistance proceeding from the vibrations of the conductor were only produced when it was broken, the molecular movements were arrested by the lateral resistances which were equal and opposite, but that if one of these resistances were destroyed, the molecular movement could be freely developed. He considers that an imperfect contact is equivalent to the suppression of one of these resistances, and as soon as this movement can take place, the molecular expansions and contractions which result from the vibrations must correspond to the increase or diminution of resistance in the circuit. We need not pursue Mr. Hughes's theory further, since it would take too long to develope it, and we must continue our examination of the different properties of the microphone.[17]

Carbon, as we have said, is not the only substance which can be employed to form the sensitive organ of this system of transmission. Mr. Hughes has tried other substances, including those which are good conductors, such as metals. Iron afforded rather good results, and the effect produced by surfaces of platinum when it was greatly subdivided was equal, if not superior, to that furnished by the mercurised carbon. Yet since the difficulty of making instruments with this metal is greater, he prefers the carbon, which resembles it in being incapable of oxidation.

We have already said that the microphone may be used as a thermoscope, in which case it must have the special arrangement represented in fig. 43. Under these conditions, heat, reacting on the conductivity of these contacts, may cause such variations in the resistance of the circuit that the current of three Daniell cells will be annulled by approaching the hand to the tube. In order to estimate the relative intensity of the different sources of heat, it will be enough to introduce into the circuit of the two electrodes A and B, fig. 43, a battery P, of one or two Daniell cells, and a moderately sensitive galvanometer G. For this purpose one of 120 turns will suffice. When the deviation decreases, it shows that the source of heat is superior to the surrounding atmosphere; and conversely, that it is inferior when the deviation increases. Mr. Hughes says that the effects resulting from the intervention of sunshine and shadow are shown on the instrument by considerable variations in the deviations of the galvanometer. Indeed it is so sensitive to the slightest variations of temperature that it is impossible to maintain it in repose.

I have repeated Mr. Hughes's experiments with a single Leclanché cell, and for this purpose I employed a quill, filled with five fragments of carbon, taken from the cylindrical carbons of small diameter which are made by M. Carré for the electric light. I have obtained the results which are mentioned by Mr. Hughes, but I ought to say that the experiment is a delicate one. When the pressure of the fragments of carbon against each other is too great, the current traverses them with too much force to allow the calorific effects to vary the deviation of the galvanometer, and when the pressure is too slight, the current will not pass through them. A medium degree of pressure must therefore be effected to ensure the success of the experiment, and when it is obtained, it is observed that on the approach of the hand to the tube, a deviation of 90° will, after a few seconds, diminish, so that it seems to correspond with the approach or withdrawal of the hand. But breathing produces the most marked effects, and I am disposed to believe that the greater or less deviations produced by the emission of articulate sounds when the different letters of the alphabet are pronounced separately, are due to more or less direct emissions of heated gas from the chest. It is certain that the letters which

require the most strongly marked sounds, such as A, F, H, I, K, L, M, N, O, P, R, S, W, Y, Z, produce the greatest deviations of the galvanometric needle.

In my paper on the conductivity of such bodies as are moderately good conductors, I had already pointed out this effect of heat upon divided substances, and I also showed that after a retrograde movement, which is always produced at once, a movement takes place in an inverse direction to the index of the galvanometer when heat has been applied for some instants, and this deviation is much greater than the one which is first indicated.

In a paper published in the 'American Scientific Journal,' June 28, 1878, Mr. Edison gives some interesting details on the application of his system of a telephonic sender to measuring pressures, expansions, and other forces capable of varying the resistance of the carbon disk by means of greater or less compression. Since his experiments on this subject date from December 1877, he again claims priority in the invention of using the microphone as a thermoscope; but we must observe that according to Mr. Hughes's arrangement of his instrument, the effect produced by heat is precisely the reverse of the effect described by Mr. Edison. In fact, in the arrangement adopted by the latter, heat acts by increasing the conductivity acquired by the carbon under the increased pressure produced by the expansion of a body sensitive to heat: in Mr. Hughes's system, the effect produced by heat is precisely the contrary, since it then acts only on the contacts, and not by means of pressure. Therefore the resistance of the microphone-thermoscope is increased under the influence of heat, instead of being diminished. This contrary effect is due to the division of some substance which is only a moderate conductor, and I have shown that under such conditions these bodies, when only slightly heated, always diminish the intensity of the current which they transmit. I believe that Mr. Edison's arrangement is the best for the thermoscopic instrument, and makes it possible to measure much less intense sources of heat. Indeed he asserts that by its aid the heat of the luminous rays of the stars, moon, and sun may be measured, and also the variations of moisture in the air, and barometric pressure.

This instrument, which we give fig. 50, with its several details, and with the rheostatic arrangement employed for measuring, consists of a metallic piece A fixed on a small board C, and on one of its sides there is the system of platinum disks and carbons shown in fig. 28. A rigid piece G, furnished with a socket, serves as the external support of the system, and into this socket is introduced the tapering end of some substance which is readily affected by heat, moisture, or barometric pressure. The other extremity is supported by another socket I, fitted to a screw-nut H, which may be more or less tightened by a regulating screw. If this system is introduced into a galvanometric circuit _a, b, c, i, g_, provided with all the instruments of the electric scale of measure, the variations in length of the substance inserted are translated by greater or less deviations of the galvanometric needle, which follow from the differences of pressure resulting from the lengthening or shortening of the surface capable of expansion which is inserted in the circuit.

[Illustration: FIG. 50.]

The experiments on the microphone made in London at the meeting of the Society of Telegraphic Engineers on May 25, 1878, were wonderfully successful, and they were the subject of an interesting article in the 'Engineer' of May 31, which asserts that the whole assembly heard the microphone speak, and that its voice was very like that of the phonograph. When the meeting was informed that these words had been uttered at some distance from the microphone, the Duke of Argyll, who was present, while admiring the important discovery, could not help exclaiming that this invention might have terrible consequences, since, for instance, if one of Professor Hughes's instruments were placed in the room in Downing Street, in which Her Majesty's ministers hold their cabinet council, their secrets might be heard in the room in which the present meeting took place. He added that if one of these little instruments were in the pocket of Count Schouvaloff, or of Lord Salisbury, we should at once be in possession of the secrets for which all Europe was anxiously waiting. If these instruments were able to repeat all the conversations held in the room in which they stood, they might be really dangerous, and the Duke thought that Professor Hughes, who had invented such a splendid yet perilous instrument, ought next to seek an antidote for his discovery. Dr. Lyon Playfair, again, thought that the microphone ought to be applied to the aërophone, so that by placing these instruments in the two Houses of Parliament, the speeches of great orators might be heard by the whole population within five or six square miles.

The experiments lately made with the microphone at Halifax show that the Duke of Argyll's predictions were fully justified. It seems that a microphone was placed on a pulpit-desk in a church in Halifax, and connected by a wire about two miles long with a telephone placed close to the bed of a sick person, who was able to hear the prayers, the chanting, and the sermon. This fact was communicated to me by Mr. Hughes, who heard it from a trustworthy source, and it is said that seven patients have subscribed for the expense of an arrangement by which they may hear the church services at Halifax without fatigue.

The microphone has also lately been applied to the transmission of a whole opera, as we learn from the following account in the 'Journal Télégraphique,' Berne, July 25, 1878:--

'A curious micro-telephonic experiment took place on June 19 at Bellinzona, Switzerland. A travelling company of Italian singers was to perform Donizetti's opera, "Don Pasquale," at the theatre of that town. M. Patocchi, a telegraphic engineer, took the opportunity of making experiments on the combined effects of Hughes's carbon microphone as the sending instrument, and Bell's telephone as the receiver. With this object he placed a Hughes microphone in a box on the first tier, close to the stage, and connected it by two wires, from one to half a millimètre in thickness, to four Bell receivers, which were placed in a billiard-room above the vestibule of the theatre, and inaccessible to sounds within the theatre itself. A small battery of two cells, of the ordinary type used in the Swiss telegraphic service, was inserted in the circuit, close to the Hughes microphone.

'The result was completely successful. The telephones exactly reproduced, with wonderful purity and distinctness, the instrumental music of the orchestra, as well as the voices of the singers. Several people declared that they did not lose a note of either, that the words were heard perfectly; the airs were reproduced in a natural key, with every variation, whether _piano_ or _forte_, and several amateurs assured M. Patocchi that by listening to the telephone they were able to estimate the musical beauty, the quality of the singers' voices, and the general effect of the piece, as completely as if they had been among the audience within the theatre.

'The result was the same when resistances equivalent to 10 kilomètres were introduced into the circuit, without increasing the number of cells in the battery. We believe that this is the first experiment of the kind which has been made in Europe, at least in a theatre, and with a complete opera; and those who are acquainted with the delicacy and grace of the airs in "Don Pasquale" will be able to appreciate the sensitiveness of the combined instruments invented by Hughes and Bell, which do not suffer the most delicate touches of this music to be lost.'

Although experiments with the microphone are of such recent date, they have been very various, and among other curious experiments we learn from the English newspapers that the attempt has been made to construct an instrument on the same principle as the telephone, which shall be sensitive to the variations of light. It is known that some substances, and particularly selenium, are electrically affected by light, that is, that their conductivity varies considerably with the greater or less amount of light which is shed upon them. If, therefore, a circuit in which a substance of this nature is inserted, is abruptly subjected to a somewhat intense light, the increase of resistance which results from it ought to produce a powerful sound in a telephone inserted in the circuit. This fact has been verified by experiment, and Mr. Willoughby Smith infers from it, as we have already suggested, that the effects produced in the microphone are due to variations of resistance in the circuit, which are produced by more or less close contacts between imperfect conductors.

In order to obtain this effect under the most favourable conditions, Mr. Siemens employs two electrodes, consisting of network of very fine platinum wire, fitting into each other like two forks, of which the prongs are interlaced. These electrodes are inserted between two glass plates, and a drop of selenium, dropped in the centre of the two pieces of network, connects them on a circular surface large enough to establish sufficient conductivity in the circuit. It is on this flattened drop that the ray of light must be projected.

APPLICATIONS OF THE MICROPHONE.

The applications of the microphone increase in number every day, and in addition to those of which we have just spoken, there are others of really scientific and even of practical interest. Among the number is the use which can be made of it as a system of relays for telegraphy, in science for the study of vibrations imperceptible to our senses, in medicine and surgery, and even in manufactures.

Its application to Scientific Research.--We have seen that several physicists, including Messrs. Spottiswoode, Warwick, Rossetti, Canestrelli, Wiesendanger, Lloyd, Millar, Buchin, and Blyth, have been able to hear what is said in a telephone which has no iron diaphragm, but it was so difficult to establish the fact that it has been often disputed. More certain evidence was desirable, and the microphone is an opportune agent for affording it.

The 'Telegraphic Journal' of September 1, 1878, observes that M. du Moncel, in order to claim the victory in his controversy with Colonel Navez, had still to show that the sounds which appeared to be inarticulate in telephones without a diaphragm might become intelligible if they were intensified. This has been done for him by the use of Mr. Hughes's microphone, and the following

experiments were made for the purpose.

1. If a magnetising coil, surrounding a bar of soft iron, is inserted in the circuit of a microphone, with a battery of three cells, the ticking of a watch and other sounds of the same kind may be heard on approaching the ear to the electro-magnet which has been thus constituted. It is true that these sounds are very faint when they are not amplified, but if the electro-magnet is fastened to a board, and a second microphone is fixed to the same board, the sounds produced by the electro-magnet are magnified, and become distinctly audible in the telephone which is placed in connection with this second microphone.

2. These sounds may be further amplified by resting one of the extremities of the core of the electro-magnet on one of the poles of a permanent magnet, which is fixed upon the board. Articulate speech may then be heard in the telephone which is placed in connection with the microphone resting on the board, and the point at issue between MM. Navez and Du Moncel is completely decided in this way: for the auxiliary microphone can only propagate and amplify the vibration of articulate sounds, which are communicated by the bar magnet of the coil to the board on which the two instruments are placed. In this way it would be possible to render articulate sounds perceptible to M. Navez, when transmitted by the bar magnet of a telephone without a diaphragm.

3. When a second bar magnet rests on the free pole of the electro-magnet, so as to present to it a pole of the same nature as the one with which it is already in communication--in a word, if a bar is placed between the two poles of a horseshoe electro-magnet, the effects are still more marked, and hence it may be assumed that the bar reacts as an armature, by concentrating the lines of magnetic force in the vicinity of the helix.

4. When the two poles of a horseshoe magnet are inserted together inside a coil, their effects are equally energetic, although by this arrangement one of the poles might be expected to neutralise the effect of the other: but the most important effects have been obtained by placing an armature of soft iron across the poles of the magnet which has been already inserted in the coil. Under these conditions articulate sounds are distinctly heard.

These experiments were confirmed by Mr. F. Varley, in a letter published in the ‘Telegraphic Journal’ of September 15, 1878, and among the fresh experiments mentioned by him, we will quote those which he made with an iron tube inserted in a helix, in which the two opposite poles of two bar magnets are introduced. These poles are only separated from each other by the interval of an inch, so that the centre of the iron tube may be strongly magnetised.

Mr. Varley says that this last arrangement reproduces the articulate sounds which issue from a sending microphone, and this experiment is more decisive than that of Professor Hughes, in which case it might be supposed that the bar magnet, resting on the polar end of an electro-magnetic bar, was only a modification of the disk in the Bell telephone, set in vibration by the alternate currents passing through the helix, and that these vibrations were communicated to the board, and became sensible when enlarged by the microphone. But such an objection cannot be alleged in the case of the arrangement described above, for since the sound is produced between the current passing into the helix and the magnetic current of the bar, it can only be the result of a vibration produced by a disturbance of the reciprocal relations subsisting between these two elements. Mr. Varley adds that these experiments confirm M. du Moncel’s researches, which have thrown considerable light upon the causes which are at work in the action of the speaking telephone, and with which we have hitherto been imperfectly acquainted.

Its application to Telephonic Relays.--In February 1878, I first began to consider the mode of forming telephonic relays, but I was checked by the discovery that there was no vibration in the receiving telephone, and I made the following communication on the subject to the Académie des Sciences on February 25:--‘If the vibrations of the disk in the receiving telephone were the same as those of the sending telephone, it is easy to see that if a telephone with a local battery, acting both as sender and receiver, were substituted for the receiving telephone, it might, by the intervention of the induction coil, act as a relay, and might therefore not only amplify the sound, but also transmit it to any distance. It is, however, doubtful whether the vibrations of the two corresponding disks are of the same nature, and if the sound be due to molecular contractions and expansions, the solution of the problem becomes much more difficult. Here is therefore a field for experiments.’ These experiments have been successfully made by Mr. Hughes, who acquainted me with them early in June 1878, and they led to the discovery of a most interesting system of microphonic relays.

On a wooden board of moderate size, such as a drawing board, he placed a microphone with a carbon brought to a fine point at each end, and fixed in a vertical position. One or more telephones were placed in the circuit, with their membranes facing the board, and a continuous sound was heard, sometimes resembling a musical note, sometimes the singing of boiling water in an oven; and the sound, which could be heard at a distance, went on indefinitely, as long as the electric force was exerted. Mr. Hughes explains this phenomenon in the following way.

The slightest shock which affects the microphone has the effect of sending currents, more or less broken, through the telephones, which transform them into sound vibrations, and since these are mechanically transmitted by the board to the microphone, they maintain and even amplify its action, and produce fresh vibrations on the telephones. Thus a fresh action is exerted on the microphone, and so on indefinitely. Again, if a second microphone, in connection with another telephonic circuit, be placed upon the same board, we have an instrument which acts as a telephonic relay, that is, it transmits to a distance the sounds communicated to the board, and these sounds may serve either as a call, or as the elements of a message in the Morse code, if a Morse manipulator is placed in the circuit of the first microphone. Mr. Hughes adds that he has made several very successful experiments with this system of instruments, although he only employed a Daniell battery of six cells without any induction coil. By fastening a pasteboard tube, 40 centimètres in length, to the receiving telephone, he was able to hear in all parts of a large room the continuous sound of the relay, the ticking of a watch, and the scratching of a pen upon paper. He did not try to transmit speech, since it would not have been reproduced with sufficient distinctness under such conditions.

Since this first attempt, Mr. Hughes has arranged another and still more curious system of microphonic relays, for which two microphones with vertical carbons are required. He places two microphones of this description on a board, and connects one of them with a third microphone, which acts as a sender, while the second is in communication with a telephone and a second battery: in this way the words uttered before the sender are heard in the telephone, without employing any electro-magnetic organ for the telephonic relay.

In August 1878, Messrs. Houston and Thomson likewise arranged a system of telephonic relays which only differs from that of Mr. Hughes in the particular of having the microphone fixed on the diaphragm of the telephone, and not on the board beside it. The system consists of three vertical microphones, which can be combined for tension or quantity, according to the conditions for which they are required. The model of this instrument was represented in the ‘Telegraphic Journal’ of August 15, 1878, to which we must refer our readers, if they wish for further information on the subject.

Its application to Medicine and Surgery.--The extreme sensitiveness of the microphone suggested its use for the observation of sounds produced within the human body, so that it might serve as a stethoscope for listening to the action of the lungs and heart. Dr. Richardson and Mr. Hughes are now busy in the attempt to carry out this idea, but so far the result is not very satisfactory, although they still hope to succeed. Meanwhile, M. Ducretet has made a very sensitive stethoscopic microphone, which we represent in fig. 51. It consists of a carbon microphone C P, with a simple contact, of which the lower carbon P is fitted to one of M. Marais’ tambourines with a vibrating membrane T. This tambourine is connected with another T′, by a caoutchouc tube, which is to be applied to the different parts of the body which demand auscultation, and which is therefore termed the _tambour explorateur_. The sensitiveness of the instrument is regulated by means of a counterpoise P O, which is screwed upon the arm of a bent lever, and to this the second carbon C is fixed. The extreme sensitiveness of M. Marais’ tambourines in transmitting vibrations is well known, and since their sensitiveness is further increased by the microphone, the instrument becomes almost too impressionable, since it reveals all sorts of sounds, which it is difficult to distinguish from each other. Such an instrument can only be of use when entrusted to experienced hands, and a special education of the organ of hearing is needful, in order to turn it to account.

[Illustration: FIG. 51.]

In a work lately published by M. Giboux on the application of the microphone to medicine, this stethoscopic system is rather severely criticised, and not without reason if, as M. Giboux asserts, it is only sensitive to the movements which take place on the surface of the body, and those which are internal are either lost or altogether changed in character. But without pronouncing on the improvements which may ultimately be made in the instrument, M. Giboux thinks that its most important use in medical practice consists in its allowing a certain number of students to observe with the professor the different sounds of the body, to study them with him in their different phases, and thus to profit more readily by his teaching. A microphonic circuit might bifurcate between several telephones, so that each person might hear for himself what is heard by others.

The most important application of the instrument to surgical purposes has lately been made by Sir Henry Thompson, aided by Mr. Hughes, for the examination of the bladder in cases of stone. It enables him to ascertain the presence and precise position of calculi, however small they may be. For the purpose of research, he uses a sound, made of a Maillechort rod, a little bent at the end, and placed in communication with a sensitive carbon microphone. When the sound is moved about in the bladder, the rod comes in contact with stony particles, even if they are no larger than a pin’s head, and friction ensues, producing in the telephone vibrations which can be easily distinguished from those caused by the simple friction of the rod on the soft tissues of the sides of the bladder. The arrangement of the instrument is shown in fig. 52. The microphone is placed in the handle which contains the

sound, and is the same as that given in fig. 42, but of smaller size, and the two conducting wires _e_ which lead to the telephone, issue from the handle by the end _a_ opposite to that _bb_ to which the sound _dd_ is screwed. As this instrument is not intended to reproduce speech, retort carbons instead of wood carbons may be used.

[Illustration: FIG. 52.]

Some deaf people, whose sense of hearing is not completely destroyed, have been able to hear by an expedient based upon the principle of the microphone. For this purpose two telephones, connected by a metallic crown, which is placed on the temples, are applied to the ears of the deaf person, and the telephones are placed in communication with a battery microphone, which hangs to the end of a double conducting wire. The deaf man keeps the microphone in his pocket, and presents it as an acoustic tube to the person who wishes to converse with him. Mr. Hughes's speaker, represented fig. 42, is the one used.

Various Applications.--The microphone may be used in many other ways, some of which are suggested in the 'English Mechanic' of June 21, 1878. The article states that by means of this instrument, engineers will be able to estimate the effects of the vibrations caused on old and new buildings by the passage of heavy loads; a soldier will be able to discover the enemy's approach when he is several miles off, and may even ascertain whether he has to do with artillery or cavalry; the approach of ships to the neighbourhood of torpedoes may be automatically heralded on the coast by this means, so that an explosion may be produced at the right moment.

It has also been proposed to use the microphone to give notice of an escape of gas in coal-mines. The gas, in escaping from between the seams of coal, makes a whistling noise, which might, with the aid of the microphone and telephone, be heard at the top of the shaft. Again, it has been suggested that the microphone might be used as a seismograph to reveal the subterranean noises which generally precede earthquakes and volcanic eruptions, and which would be much intensified by this instrument. It might even be of use to Signor Palmieri for his observations in the Vesuvius Observatory.

The microphone has also been used by Mr. Chandler Roberts to render the diffusion of gaseous molecules through a porous membrane sensible to the ear.

As might have been expected, the acclamation with which Mr. Hughes's invention was received led to the assertion of other claims to priority, and in addition to that of Mr. Edison, on which we have already given our opinion, there are several others, showing that if some microphonic effects were discovered at different times before the date of Mr. Hughes's discovery, they could not have been considered important, since they were not even announced. Among the number was that of Mr. Wentworth Lascelles Scott, specified in the 'Electrician' of May 25, 1878, and that of M. Weyher, presented to the Société de Physique, Paris, in June 1878. Another, made by M. Dutertre, is of somewhat greater importance, for his experiments were reported in the Rouen papers in February of the same year: yet there is no just ground for such claims, since the earliest date of his experiments is subsequent to the experiments first made by Mr. Hughes. These began early in December 1877, and in January 1878 they were exhibited to officials of the Submarine Telegraph Company, as Mr. Preece declared in a letter addressed to the several scientific men.

EXTERNAL INFLUENCE ON TELEPHONIC TRANSMISSIONS.

The obstacles which occur in telephonic transmissions proceed from three causes: 1. The intensity of sound is diminished by the loss of current in transmission--a loss which is much greater in the case of induced currents than in those received from a battery. 2. Confusion is caused by the influence of adjacent currents. 3. The induction from one wire to another. This last influence is much greater than is usually supposed. If two perfectly insulated wires are placed side by side, one in communication with the circuit of an electric bell, and the other with the circuit of a telephone, the latter will repeat the sounds of the bell with an intensity often great enough to act as a call without applying the instrument to the ear. MM. Pollard and Garnier, in their interesting experiments with the induced currents of the Ruhmkorff coil, have ascertained that in this way not merely sounds may be obtained which correspond with the induced currents resulting from the action of the primary current, but also those which result from the action of the secondary current on other helices, which are termed currents of the second order. These different reactions frequently cause the telephonic transmissions made on telegraphic lines to be disturbed by irregular sounds, arising from the electric transmissions on adjoining lines; but it does not appear that these influences altogether neutralise each other, so that conversation held in the ordinary way and a message sent in the Morse code may be heard simultaneously.

At the Artillery School, Clermont, a telephonic communication has been established, for the sake of experiments, between the school and the butts, which are at a distance of about eight miles. Another communication of the same kind has been established between the Clermont Observatory and the one at Puy-de-Dôme, which is nearly nine miles from the former. These two lines are carried on the same posts for a course of six miles, together with an ordinary telegraphic wire, and for a distance of 330 yards there are seven other such wires. The two telephonic wires are separated from each other by a space of 85 centimètres. The following facts have been observed under these conditions.

1. The school telephone is perfectly able to read off from their sound the Morse messages which pass through the two adjacent telegraph wires, and the ticking of the instrument does not at all interfere with the vocal communication of the telephone, nor render it inaudible.

2. The two adjacent telegraphic lines, although not in contact, confuse their messages together, and it has sometimes been possible to hear messages from Puy-de-Dôme at the school through the wire which runs to the butts, although the distance between the two lines is nowhere less than 85 centimètres.

These inconveniences have been in some degree remedied by inserting strong resistances in the circuit, or by putting the current to earth at some distance from the telephonic stations.

M. Izarn, Professor of Physics at the Lycée, Clermont, holds that telephonic electric currents may readily be turned aside by the earth, especially if in the course of their passage they encounter metallic conductors, such as gas or water pipes. He writes as follows on the subject, in a paper addressed to the Académie des Sciences, on May 13, 1878:--'I set up a telephone in the Clermont Lycée with a single wire, more than 50 yards in length, which crosses the court-yard of the Lycée, and goes from the laboratory, where it is suspended to a gas-burner, to a room near the porter's lodge, where it is suspended to another gas-burner. When I applied my ear to the telephone, I could distinctly hear the telegraphic signals, Morse or otherwise, which came either from the telegraph office at Clermont, or from the telephone office which was at work between the School of Artillery and the butts below Puy-de-Dôme, a distance of eight miles. I could overhear words, and especially the military orders issued at the butts for the purpose of being heard at the school. Yet my wire is perfectly independent of those used for signalling, and is even very remote from them; but as the wires of the telegraph office and of the School of Artillery go to earth at a little distance from the gas-pipes, it is probable that this phenomenon is caused by a diversion of the current produced in my wire, by means of the earth and the network of metal pipes.'

Mr. Preece made the same remark in his notice of 'some physical points connected with the telephone.' Again, we read in the 'Telegraphic Journal' of June 15, 1878, that in a telephonic concert transmitted from Buffalo to New York, the singers at Buffalo were heard in an office placed outside the telegraphic circuit in which the transmission was effected. On enquiry, it was ascertained that the wire through which the telephonic transmission took place, was at one point in its course close to the one which directly transmitted the musical sounds, but the distance between the two wires was not less than ten feet.

When the circuits are altogether metallic, there is much less risk of confusion, and M. Zetzche declares that sounds proceeding from other wires are in this case little heard, and then only momentarily, so that it is much more easy to hear with this arrangement than with the one in ordinary use. 'It is not,' he says, 'the resistances of the wire, but rather the diversions of the current near the posts, which interfere with telephonic correspondence on long lines above ground. This was proved by the following experiments:--I connected the telegraphic line from Dresden to Chemnitz with a line from Chemnitz to Leipzig (54 miles), which made a circuit of 103 miles, going to earth at its two extremities. There was no communication between Dresden and Leipzig, but Leipzig and Dresden could communicate with ease, in spite of the greater extent of line. I broke the connection with earth, first at Leipzig, then simultaneously at Leipzig and Dresden, and I observed the following effects. When insulation took place at Leipzig only, the telephone could be heard at the stations of Dresden, Riesa, and Wurzen; when the line was insulated at both ends, the communication was good between the two latter stations, but it was observed that at the intermediate station the words spoken at Wurzen were more distinctly heard than the words spoken at Riesa were heard at Wurzen. Since the distance from Wurzen to Leipzig is little more than half that from Riesa to Dresden, there are consequently nearly twice as many posts on the latter line, which carry the currents to earth, and hence I conclude that these diversions of current explain the possibility of conversing on an insulated line, and also why sounds are more distinctly heard at the Riesa station in consequence of the greater intensity of current still remaining on the line.'

Some vibrations also result from the action of currents of air on telegraphic wires, which produce the humming sound so well known on some lines, and these may also react on the telephone; but they are in this case generally mechanically transmitted, and they may be distinguished from the others, if the sounds which ensue are heard after the telephone is excluded from the circuit by a break with a short circuit and after the communication to earth established behind the telephone has been broken.

The induced reactions caused by the line wires on each other are not the only ones which may be observed on a telephonic circuit: every manifestation of electricity near a telephone may produce sounds of greater or less force. Of this we have already given a proof in M. d'Arsonval's experiments, and others by M. Demoget demonstrate the fact still more clearly. In fact, if a small bar magnet provided with a vibrator be placed before one of the telephones of a telephonic circuit, and the vibrating plate of the telephone be removed, in order to draw away the sound produced by the vibrator, its humming noise may be distinctly heard on the second telephone of the circuit; a noise which attains its maximum when the two extremities of the electro-magnet are at their nearest point to the telephone without a diaphragm, and it is at its minimum when this electro-magnet is presented to it along its neutral line. M. Demoget supposes that the action which is exerted in this instance is that of a magnet exerting two inducing actions which are opposite and symmetrical, with a field limited by a double paraboloid and with an axis, according to his experiments, which extended 55 centimètres beyond the magnetic core, and a vertical diameter of 60 centimètres. He believes that in this way it would be easy to telegraph on the Morse system, and that, in order to do so, it would only be necessary to apply a key to the inducing electro-magnet.

Mr. Preece points out three ways of overcoming the difficulty presented by the induced reactions caused by the wires on each other.

1. By increasing the intensity of the transmitted currents, so as to make them decidedly stronger than the induced currents, and to reduce the sensitiveness of the receiving telephone.

2. To place the telephonic wire beyond the range of induction.

3. To neutralise the effects of induction.

The first mode may be effected by Edison's battery system, and we have seen that it is very successful.

In order to put the second mode in practice, Mr. Preece says that it would be necessary to study the two kinds of induction which are developed on telegraphic lines: electro-static induction, analogous to that produced on submarine cables, and electro-dynamic induction, resulting from electricity in motion. In the former case, Mr. Preece proposes to interpose between the telephone wire and the other wires a conducting body in communication with the earth, capable of becoming a screen to the induction by itself absorbing the electro-static effects. He says that this might be accomplished by surrounding the telegraphic wires adjacent to the telephonic wire with a metallic envelope, and then plunging them in water. He adds that the effects of static induction are not completely destroyed in this way, since the substance used is a bad conductor, but they are considerably reduced, as he has proved by experiments between Dublin, Holyhead, Manchester, and Liverpool. In the second case, Mr. Preece admits that an iron envelope might paralyse the electro-dynamic effects produced by absorbing them, so that if insulated wires were employed, covered with an iron case, and communicating with the earth, the two induced reactions would be annulled. We will not follow Mr. Preece in his theory as to these effects--a theory which seems to us open to question, but we content ourselves with pointing out his proposed mode of attenuation.

In order to carry out the third expedient, it might be thought that it would be enough to employ a return wire instead of going to earth, for under such conditions the currents induced on one of the wires would be neutralised by those resulting from the same induction on the second wire, which would then act in an opposite direction; but this mode would only be successful when there is a very small interval between the two telephone wires, and they are at a considerable distance from the other wires. When this is not the case, and they are all close together, as in submarine or subterranean cables, consisting of several wires, this mode is quite inefficient. A small cable, including two conductors, insulated with gutta-percha, may be successfully carried through the air.

The use of two conductors has the further advantage of avoiding the inconvenience of stray currents on the line and through the earth, which, when the communications to earth are imperfect, permit the line current to pass more or less easily into the telephonic line.

In addition to the disturbing causes in telephonic transmission we have just mentioned, there are others which are also very appreciable, and among them are the accidental currents which are continually produced on telegraphic lines. These currents may

proceed from several causes, at one time from atmospheric electricity, at another from terrestrial magnetism, at another from thermo-electric effects produced upon the lines, at another from the hydro-electric reactions produced on the wires and disks in communication with the earth. These currents are always very unstable, and consequently they are likely, by reacting on the transmitted currents, to modify them so as to produce sounds upon the telephone. Mr. Preece asserts that the sound proceeding from earth currents somewhat resembles that of falling water. The discharges of atmospheric electricity, even when the storm is remote, produce a sound which varies with the nature of the discharge. When it is diffused and the clap takes place near at hand, Dr. Channing, of Providence, U.S., says that the sound resembles that produced by a drop of fused metal when it falls into water, or, still more, that of a rocket discharged at a distance: in this case it might seem that the sound would be heard before the appearance of the flash, which clearly shows that the electric discharges of the atmosphere only take place in consequence of an electric disturbance in the air. Mr. Preece adds that a wailing sound is sometimes heard, which has been compared to that of a young bird, and which must proceed from the induced currents which terrestrial magnetism produces in the metallic wires when placed in vibration by currents of air.

M. Gressier, in a communication made to the Académie des Sciences on May 6, 1878, has spoken of some of these sounds, but he is totally mistaken in the source to which he ascribes them.

‘In addition to the crackling sound caused by the working of telegraph instruments on the adjacent lines, a confused murmur takes place in the telephone, a friction so intense that it might sometimes be thought that the vibrating disk was splitting. This murmur is heard more by night than by day, and is sometimes intolerable, since it becomes impossible to understand the telephone, although nothing is going on in the office to disturb the sound. The same noise is heard when only one telephone is used. A good galvanometer inserted in the circuit reveals the presence of sensible currents, sometimes in one direction, sometimes in another.’

I studied these currents for a long time with the galvanometer, and made them the subject of four papers which were laid before the Académie des Sciences in 1872, and I am convinced that they have in general nothing to do with atmospheric electricity, but result either from thermo-electric or hydro-electric influence. They take place constantly and in all weathers on telegraph lines, whether these lines are insulated at one end, or in contact with the earth at both ends. In the first case, the polar electrodes of the couple are formed by the telegraph wire and the earth plate, generally of the same nature, and the intermediate conducting medium is represented by the posts which support the wire and the earth which completes the circuit. In the second case, the couple is formed in almost the same way, but the difference in the chemical composition of the ground at the two points where the earth plates are buried, and sometimes their different temperature, exert a strong influence. If only the first case be considered, it generally happens that on fine summer days the currents produced during the day are inverse to those which are produced by night, and vary with the surrounding temperature in one or the other direction. The presence or absence of the sun, the passage of clouds, the currents of air involve abrupt and strongly marked variations, which may be easily followed on the galvanometer, and which cause more or less distinct sounds in the telephone.

During the day, the currents are directed from the telegraph line to the earth plate, because the heat of the wire is greater than that of the plate, and these currents are then thermo-electric. During the night, on the other hand, the wire is cooled by the dew, which causes a greater oxidation on the wire than that which takes place on the plate, and the currents then become hydro-electric.

I say more about these currents because, in consequence of a mistaken belief as to their origin, it has been supposed that the telephone might serve for the study of the variations of the atmospheric electricity generally diffused through the air. Such an application of the telephone would, under these conditions, be not only useless, but also misleading, by inducing the study of very complex phenomena, which could lead to nothing more than I have already stated in my different papers on the subject.

Certain local influences will also produce sounds in the telephone. Thus the distension of the diaphragm by the moist heat of the breath, when the instrument is held before the mouth in speaking, causes a perceptible murmur.

From the electro-static reactions, so strongly produced on the submarine cables, in consequence of electric transmissions, it might be supposed that it would not be easy to hold telephonic correspondence through this kind of conductor, and, to ascertain the fact, an experiment was made on the cable between Guernsey and Dartmouth, a distance of sixty miles. Articulate speech, only a little indistinct, was, however, perfectly transmitted. Other experiments, made by Messrs. Preece and Wilmot, on an artificial submarine cable, placed in conditions analogous to those of the Atlantic cable, showed that a telephonic correspondence might be kept up at a distance of a hundred miles, although the effects of induction were apparent. At the distance of 150 miles, it was somewhat difficult to hear, and the sounds were very faint, as if some one were speaking through a thick partition. The sound diminished rapidly until

the distance of 200 miles was reached, and after that it became perfectly indistinct, although singing could still be heard. It was even possible to hear through the whole length of the cable, that is, for 3,000 miles, but Mr. Preece believed this to be due to the induction of the condenser on itself: he holds, however, that singing may be heard at a much greater distance than speech, owing to the more regular succession of electric waves.

Mr. Preece also made experiments on the subterranean telegraphs between Manchester and Liverpool, a distance of 30 miles, and found no difficulty in exchanging correspondence; and it was the same with the cable from Dublin to Holyhead, a distance of 67 miles. This cable had seven conducting wires, and when the telephone was connected with one of them, the sound was repeated through all the others, but in a fainter degree. When the currents of the telegraphic instruments passed through the wires, the induction was apparent, but not so great as to prevent telephonic communication.

ESTABLISHMENT OF A TELEPHONIC STATION.

Although the telephonic system of telegraphy is very simple, yet certain accessory arrangements are indispensable for its use. Thus, for example, an alarum call is necessary, in order to know when the exchange of correspondence is to take place, and information that the call has been heard is likewise necessary. An electric bell is therefore an indispensable addition to the telephone, and since the same circuit may be employed for both systems, if a commutator is used, it was necessary to find a mode of making the commutator act automatically, so as to maintain the simple action of the system which constitutes its principal merit.

MM. Pollard and Garnier's System.--With this object, MM. Pollard and Garnier devised a very successful arrangement last March, which employs the weight of the instrument to act upon the commutator.

For this purpose, they suspended the instrument to the end of a spring plate, fastened between the two contacts of the commutator. The circuit wire corresponds with this plate, and the two contacts correspond, the one with the telephone, the other with the bell. When the telephone hangs below the spring-support, that is, when it is not at work, its weight lowers the spring plate on the lower contact, and the communication of the line with the bell is established: when, on the other hand, the telephone is raised for use, the spring plate touches the higher contact, and communication is established between the line and telephone. In order to make the bell sound, it is only necessary to establish, on the wire which connects the line with the bell contact of the commutator, a breaker which can both join and break the current, and which communicates on one side with the contact of the bell, and on the other with its battery. The ordinary push of an electric bell will be sufficient, if it is supplied with a second contact, but MM. Pollard and Garnier wished to make this action also automatic, and consequently they devised the arrangement represented in fig. 53.

[Illustration: FIG. 53.]

In this system, as well as in those which have since been devised, two telephones are employed, one of which is constantly applied to the ear, and the other to the mouth, so as to make it possible to speak while listening. The telephones are supported by three wires, two of which contain flexible conductors, while the third only acts as a support.

Two of the four wires of the two telephones are connected with each other, and the other two are connected with the two binding screws of the commutator _t_, _t′_: the wires without conductors are suspended to the extremities of the two flexible plates _l_, _l′_, which correspond with earth and line.

When at rest, the weight of the telephones presses the two plates _l_, _l′_, on the lower contacts S, S′, but when the instruments are taken up these plates press against the higher contacts.

The two bell wires terminate on the lower contacts, those of the telephones on the higher contacts, and one of the poles of the battery is connected with the lower contact on the left S′, the other with the higher contact on the right T.

When at rest, the system is applied to the electric bell, and the current sent from the opposite station will follow the circuit L _l_ S S′ S′ _l′_ T, so that the call will be made. On taking up the two telephones, the circuit of the bell system is broken, and that of the telephones is established, so that the current follows the course L _l_ T _t t′_ T′ _l′_ T. If only one telephone is held at a time, the current is sent into the bell system of the opposite station, and follows the route + P S _l_ L T _l′_ T′ _t_ P --. In this way the three actions necessary for calling, corresponding, and enabling the corresponding instrument to give a call, are almost involuntarily made.

System by MM. Bréguet and Roosevelt.--In the system established by the Paris agents of the Bell company, the arrangement resembles the one just described, except that there is only one spring commutator, and the call is made with the push of an ordinary electric bell. A mahogany board is suspended from the wall, and on it are arranged, first, the ordinary electric bell system, with a sending push fixed below it; second, two forks supporting two telephones, one of which is fastened to the bar of a commutator, arranged as a Morse key. The two telephones are connected by two conducting wires, so arranged as to be capable of extension, and two of their four binding screws are in immediate connection with each other, and the other two with the earth, line, and battery, by means of the commutator, the sending push, and the bell system. The arrangement is shown in fig. 54.

[Illustration: FIG. 54.]

The commutator A consists of a metallic bar _a c_, bearing the suspension fork of one of the telephones F′ below its point of articulation: it ends in two pins _a_ and _c_, below which the two contacts of the commutator are fixed, and a spring compresses the lower arm of the bar, so as to cause the other arm to rest constantly on the higher contact. For greater security a steel tongue _a b_ is fastened to the lower end of the bar, and rubs against the small shaft _b_, which is provided with two insulated contacts, corresponding to those of the board. The bar is in communication with the line wire by means of the call-push, and the upper of the two contacts we have just described corresponds with one of the telephone wires which is inserted in the same circuit, while the other corresponds with the bell system S, which is in communication with earth. It follows from this arrangement, that when the right telephone presses its whole weight on the support, the bar of the commutator is inclined on the lower contact, and consequently the line is in direct communication with the bell, so that the call can be made. When, on the other hand, the telephone is removed from its support, the bar rests on the higher contact, and the telephones are connected with the line.

Pressure on the sending push serves to call the corresponding station: the connection of the line with the telephones is then broken, and it is established with the battery of the sending station, which sends its current through the bell of the corresponding station. In order to obtain this double effect, the contact spring of the sending push generally rests upon a contact fastened to a piece of wood shaped like a joiner's rule, which covers it in front, and below this spring there is a second contact, which communicates with the positive pole of the station battery. The other contact corresponds with the line wire, and a connection takes place between the earth wire and the negative pole of the station battery, so that the earth wire is common to three circuits:

1st. To the telephone circuit. 2nd. To that of the bell system. 3rd. To that of the local battery.

The second fork, which supports the telephone on the right, is fixed to the board, and is independent of any electric current.

It is clear that this arrangement may be varied in a thousand ways, but the model we have just described is the most practical.

Edison's System.--The problem becomes more complex in the case of battery telephones, since the battery must be common to both systems, and the induction coil must be inserted in two distinct circuits. Fig. 55 represents the model adopted in Mr. Edison's telephone.

[Illustration: FIG. 55.]

In this arrangement, there is a small stand C on the mahogany board on which the bases of the two telephones rest. The bell system S is worked by an electro-magnetic speaker P, which serves, when a Morse key is added to the system, for exchange of correspondence in the Morse code, if there should be any defect in the telephones, or to put them in working order. Above the speaker there is a commutator with a stopper D to adapt the line for sending or receiving, with or without the bell; and below the stand C the induction coil, destined to transform the voltaic currents into induced currents, is arranged in a small closed box E.

When the commutator is at reception, the line is in immediate correspondence either with the speaker or with the receiving telephone, according to the hole in which the stopper is inserted; when, on the other hand, it is at sending, the line corresponds to the secondary circuit of the induction coil. Under these conditions the action is no longer automatic; but since this kind of telephone can only be usefully employed for telegraphy, in which case those who work it are acquainted with electric apparatus, there is no inconvenience in this complication.

CALL-BELLS AND ALARUMS.

The call-bells applied to telegraphic service have been arranged in different ways. When the vibrating bells are in use, like those of which we have just spoken, it is necessary to use a battery, and the advantages offered by telephones with induced currents are

thus sensibly diminished. In order to dispense with the battery, the use of the electro-magnetic bell has been suggested.

In this case there are usually two bells, with a hammer oscillating between them, and a support formed of the polarised armature of an electro-magnet. The electro-magnetic instrument is placed below this system; it is turned by a winch, and sends the currents, alternately reversed, which are necessary to communicate the vibratory movement to the hammer, and this movement is enough to make the two bells tinkle. Below the winch of this electro-magnetic instrument there is a commutator with two contacts, which adapts the instrument for sending or receiving.

M. Mandroux has simplified this system, and has reduced it to small dimensions by the following arrangement. He fixes two magnetic cores, furnished with coils, on each of the two poles of a horseshoe magnet, composed of two bars connected by an iron coupler, and between the poles expanded by these four cores he inserts an armature, within which there is a steel spring fastened to one of these poles. In this way the armature is polarised, and oscillates under the influence of the reversed currents transmitted by an instrument of the same kind provided with an induction system. These oscillations may have the effect of producing the sound of a call-bell, and the induction system may consist of a manipulating key, fastened to a duplex system of armature, regularly applied to the magnetic cores, taken in pairs. On communicating a series of movements to this manipulator, a series of induced currents in an inverse direction are produced, which cause the armature of the corresponding station to act as we have already seen, and which may even, when necessary, furnish a series of Morse signals for a suitable manipulation. On account of the small size of this system, it might be applied to the telephonic service of the army.

The Bell Telephone Company in Paris has arranged another little call-system which is quite satisfactory and has the advantage of acting as a telephone at the same time. The model resembles the one we have termed a snuff-box telephone, and it has a button commutator by means of which the instrument is placed in communication with the electro-magnetic system of the instrument, or with a battery which is able to make the telephone vibrate with some force. To make a call, the button must be pressed, and the battery current is communicated to the corresponding instrument, which begins to vibrate when the call is made; and when notice is given of the receipt of the signal, the pressure on the button is removed, and it becomes possible to speak and receive as in ordinary telephones.

[Illustration: FIG. 56.]

M. de Weinhold's System.--M. Zetzche speaks highly of an alarum devised by Professor A. de Weinhold, which resembles that by M. Lorenz, represented in fig. 56. Its organ of sound consists of a steel bell T, from 13 to 14 centimètres in diameter, and toned to give about 420 double vibrations in a second. 'Its diameter and tone,' he says, 'are important, and any great departure from the rule laid down diminishes the effect. The opening of the bell is below, and it is fixed on a stand by its centre. A slightly curved bar magnet, provided at its two ends with iron appendices enclosed in a coil, traverses the stand. The bar magnet of the telephone also terminates in an iron appendix enclosed in a coil. In both cases the changes produced in the magnetic condition appear to be more intense than they are in magnets without appendices. The bar magnet is placed within the bell in the direction of one of its diameters, so that the appendices almost touch its sides.

'When the bell is struck on a spot about 90° from this diameter with a wooden clapper M, which acts with a spring, and is withdrawn by stretching the spring and then letting it go, as in a bell for the dinner-table, the vibrations imparted to it send currents into the coils, and these currents produce identical vibrations on the iron disk of the telephone, which are intensified by a conical resonator fitted to the telephone, so as to be easily heard some paces off. For ordinary use, the bell coil is broken into a short circuit by means of a metallic spring R, and consequently, when the bell is struck, the spring must be opened so as not to break the circuit. An instrument of the same kind has also been devised by Herr W. E. Fein at Stuttgardt.'

[Illustration: FIG. 57.]

[Illustration: FIG. 58.]

MM. Dutertre and Gouault's System.--One of the most ingenious solutions of the problem of making the telephone call has recently been proposed by MM. Dutertre and Gouault. Figs. 57 and 58 represent the opposite faces of the instrument. It consists of a kind of snuff-box telephone, like the one shown in fig. 26, and it is so arranged as to send or receive the call, according to the way in which it is placed on its stand, which is only an ordinary bracket fastened to the wall. When it is placed on the bracket so as to have the telephone mouthpiece on the outside, it is adapted for receiving, and can then give the call. When, on the other hand, its position on the bracket is reversed, it permits the other station to make the call, by producing vibrations on a vibrator under the

influence of a battery, and these vibrations reverberate in the corresponding instrument with sufficient force to produce the call. If the instrument is taken up, and the finger is placed on a small spring button, it may then be used as an ordinary telephone.

In this instrument, the magnet N S (fig. 57) is snail-shaped, like others we have mentioned, but the core of soft iron S, to which the coil E is fastened, can produce two different effects on its two extremities. On the one side, it reacts on a small armature which is fastened to the end of a vibrating disk C, fig. 58; the armature is placed against a contact fastened to the bridge B, and constitutes an electro-magnetic vibrator. For this purpose the bridge is in metallic communication with the coil wire, of which the other end corresponds with the line wire, and the spring C is mounted on an upright A, which also supports another spring D G acting on two contacts, one placed at G, and corresponding to the earth wire, the other at H, and connected with the positive pole of the battery. A small moveable button, which passes through a hole in the lid of the box, and projects beyond it, is fixed at G, and all this part of the instrument faces the bottom of the box. The upper part consists of the vibrating disk and the mouthpiece, so that the mechanism we have described is all mounted on an inner partition forming a false bottom to the box.

When the box rests upon its base, on the side shown in fig. 58, the button at G presses on the spring D G, and raises it so as to break the connection with the battery; the coil of the instrument is then united to the circuit, and consequently receives the transmitted currents, which follow this route: line wire, coil E, bridge B, spring C, spring D G, earth contact. If these currents are transmitted by a vibrator, they are strong enough to produce a noise which can be heard in all parts of a room, and consequently the call may be given in this way. If the currents are due to telephonic transmission, the instrument is applied to the ear, care being taken to put the finger on the button G, and the exchange of correspondence takes place as in ordinary instruments; but it is simpler and more manageable to insert a second telephone in the circuit for this purpose. When the box is inverted on its mouthpiece, and the button G ceases to press on the spring D G, the battery current reacts on the vibrator of the instrument, and sends the call to the corresponding station, following this route: I D A C B E, line, earth and battery; and the call goes on until the correspondent breaks the current by taking up his instrument, thus warning the other that he is ready to listen.

System of M. Puluj.--There is yet another call system, devised by M. Puluj. It consists of two telephones without mouthpieces, connected together, and with coils placed opposite the branches of two tuning-forks, tuned as nearly as possible to the same tone. A small metal bell is fixed between the opposite faces of the tuning-forks, and a wire stretched near them is provided with a small ball in contact with their branches. When the tuning-fork at the sending station is put in vibration by striking it with an iron hammer covered with skin, the tuning fork at the other station vibrates also, and its ball strikes upon the bell. As soon as the signal is returned by the second station, mouthpieces with iron diaphragms are fastened to the telephones, and the correspondence begins. It seems that, by the use of a resonator, the sound which reaches the receiving station may be so intensified as to become audible in a large hall, and the bell signal may be heard in an adjoining room, even through a closed door.

Mr. Alfred Chiddey's System.--This arrangement consists of a slender copper tube, eight inches long, and with an orifice of 1/30 of an inch, of which the lower end is soldered to the diaphragm of a telephone. A branch joint, to which an india-rubber tube is fitted, connects it with a gas jet, which is lighted and surrounded with a lamp shade, in such a way as to make it produce, under given conditions, sounds resembling those of the singing flames. A perfectly similar system is arranged at the other end of the line, in such a way that the sounds emitted in each case shall be precisely in unison. If the two systems are so regulated as not to emit sounds in their normal condition, they can be made to sing by causing a tuning-fork in the vicinity of one or the other to vibrate the same note, and then the corresponding flame will begin to sing, producing a vibration in the diaphragm of the telephone with which it is in correspondence, and hence will follow the vibration of the diaphragm of the other telephone, and consequently the vibration of the flame of the calling instrument. In this way the call signal may be made without the intervention of any battery.

APPLICATIONS OF THE TELEPHONE.

The applications of the telephone are much more numerous than might be supposed at the first glance. As far as the telegraphic service is concerned, its use must evidently be rather limited, since it cannot register the messages sent, and the speed of transmission is inferior to that of the improved system of telegraphs; yet in many cases it would be very valuable, even for a telegraphic system, since it is possible to work it without any special telegraphic training. The first comer may send and receive with the telephone, and this is certainly not the case even with the simplest forms of telegraphic instruments. This system is therefore already in use in public offices and factories, for communication in mines, for submarine works, for the navy, especially when several vessels manœuvre in the same waters, some towed by others; finally, for military purposes, either to transmit orders to different corps, or to communicate with schools of artillery and rifle practice. In America the municipal telegraphic service and that

of telegraphs limited to the area of towns are conducted in this way, and it is probable that this system will soon be adopted in Europe. Indeed, a service of this kind was established in Germany last autumn at the telegraph offices of some towns, and the London Post Office is now thinking of establishing it in England.

But, besides its use for the purposes of correspondence, the telephone can be useful to the telegraphic service itself by affording one of the simplest means of obtaining a number of simultaneous transmissions through the same wire, and even of being combined in duplex with the Morse telegraphs. Its applications in the microphonic form are incalculable, and the proverb which declares that 'walls have ears' may in this way be literally true. It is alarming to think of the consequences of such an indiscreet organ. Diplomatists must certainly redouble their reserve, and tender confidences will no longer be made with the same frankness. On this point we cannot think that much will be gained, but on the other hand the physician will probably soon make use of this invention to ascertain more readily the processes going on within the human body.

APPLICATION OF THE TELEPHONE TO SIMULTANEOUS TELEGRAPHIC TRANSMISSIONS.

The simultaneous transmission of several messages through the same wire is one of the most curious and important applications of the telephone to telegraphic instruments which can be made, and we have seen that it was this application which led Messrs. Gray and Bell to the invention of speaking telephones. The admiration which these instruments have excited has thrown the original idea into the background, although it has perhaps a more practical importance. We will now consider these systems.

An articulating telephone is not necessary in order to obtain simultaneous transmission: the musical telephones devised by MM. Petrina, Gray, Froment, &c., are quite sufficient, and a brief explanation of their principle will make this intelligible. Suppose that there are seven electro-magnetic vibrators at the two corresponding stations, which are tuned with the same tuning-fork on the different notes of the scale, and suppose that a key-board, resembling the Morse telegraph key, is arranged so that, by lowering the keys, electric reaction takes place on each vibrator: it is easy to see that these vibrators may be made to react in the same way on the corresponding vibrators of the opposite station; but they must be tuned on the same note, and the sounds emitted will continue while the keys are lowered. By keeping them down for a shorter or longer time, the long or short sounds which constitute the elements of telegraphic language in the Morse system may be obtained, and consequently an audible transmission becomes possible. Let us now suppose that a telegraphist accustomed to this mode of transmission is placed before each of the vibrators, and that they transmit different messages at the same moment in this way: the telegraphic wire will be instantaneously traversed by seven currents, broken and massed upon each other, and they might be expected to produce a medley of confused sounds on the vibrators at the receiving station; but since they each harmonise with the corresponding vibrator, they have no sensible influence except on those for which they are intended. The dominant sound may be made still more distinct by applying a Helmholtz resonator to each vibrator,[18] that is, an acoustic instrument which will only vibrate under the influence of the note to which it is tuned. In this way it is possible to select the transmitted sounds, and only to allow each _employé_ to hear that which is intended for him. Consequently, however confused the sounds may be on the receiving vibrators, the person to whom _do_ is assigned will only receive _do_ sounds, the person to whom _sol_ is assigned will only receive _sol_ sounds, so that correspondence may be carried on as well as if they had each a special wire.

In the mode we have described, this telegraphic system only admits of audible transmissions, and consequently cannot register messages. To supply this defect, it has been suggested to make the receiving vibrators react on registers, so arranging the latter that their electric organ may present such magnetic inertia, that, when it is influenced by the vibrations of sound, its effect may be maintained throughout the time of vibration. Experiments show that a Morse receiver, worked by the current of a local battery, will be enough for this purpose; so that if the musical vibrator is made to react as a relay, that is, on a contact in connection with the local battery and the receiver, the dots and dashes may be obtained on it which are the constituent elements of the Morse code.

On these principles, and considering that the musical spaces separating the different notes of the scale are such as may be easily distinguished by the resonator, seven simultaneous transmissions may be obtained on the same wire; but experience shows that it is necessary to be content with a much smaller number. Yet this number may easily be doubled by applying the mode of transmission in an opposite direction to the system.

Mr. Bell states that the idea of applying the telephone to multiple electric transmissions occurred simultaneously to M. Paul Lacour of Copenhagen, to Mr. Elisha Gray of Chicago, to Mr. Varley of London, and to Mr. Edison of New York; but there is some confusion here, for we have already seen, from reference to the patents, that Mr. Varley's system dates from 1870, that of M. Paul Lacour from September 1874, that of Mr. Elisha Gray from February 1875, and those of Messrs. Bell and Edison were still later. Yet

it appears from Mr. Gray's specification that he was the first to conceive and execute instruments of the kind. In fact, in a specification drawn up on August 6, 1874, he distinctly put forward the system we have described, and which is the basis of those of which we have still to speak. This specification was only an addition to two others made out in April and June 1874. Mr. Varley's system has only an indirect relation to the one we have described. It appears from what Mr. Bell said on the subject in a paper addressed to the Society of Telegraphic Engineers in London, that he himself only attaches a secondary interest to this invention.

He said that he had been struck with the idea that the greater or less duration of a musical sound might represent the dot and dash of the telegraphic alphabet, and it occurred to him that simultaneous telegraphic transmissions, of which the number should only be limited by the delicacy of the sense of hearing, might be obtained by suitable combinations of long and short sounds, and that these should be effected by a keyboard of tuning-forks applied to one end of a telegraphic line, and so arranged as to react electrically on electro-magnetic instruments striking on the strings of a piano. For this purpose it would be necessary to assign an employé to each of the keys for the service of transmission, and to arrange that his correspondent should only distinguish his peculiar note among all those transmitted. It was this idea, Mr. Bell adds, which led to his researches in telephony.

For several years he sought for the best mode of reproducing musical sounds at a distance by means of vibrating rheotomes: the best results were given by a steel plate vibrating between two contacts, of which the vibrations were electrically produced and maintained by an electro-magnet and a local battery. In consequence of its vibration, the two contacts were touched alternately, and the two circuits were alternately broken; the local circuit which kept the plate in vibration, and the other which was connected with the line, and reacted on the distant receiver, so as to effect simultaneous vibrations in it. A Morse key was placed in the latter circuit near the sending instrument, and when it was lowered, vibrations were sent through the line; when it was raised, these vibrations ceased, and it is easy to see that, by lowering the key for a longer or shorter time, the short and long sounds necessary for the different combinations of telegraphic language could be obtained. Moreover, if the vibrating plate of the receiving instrument were so regulated as to vibrate in unison with the sending instrument in correspondence, it would vibrate better with this sender than with another whose plate was not so adjusted.

It is evident that different sounds might be simultaneously transmitted with several plates by this arrangement of contact breaker, and that at the receiving station the sounds might be distinguished by each employé, since the one which corresponds to the fundamental note of each vibrating plate is reproduced by that plate. Consequently, the sounds produced by the vibrating plate of _do_, for example, will only be audible at the receiving station on the plate tuned to _do_, and the same will be the case with the other plates; so that the sounds will reach their destination, if not without confusion, yet with sufficient clearness to be distinguished by the employés.

Mr. Bell sums up the defects still existing in his system as follows:--1st. The receiver of the messages must have a good musical ear, in order to distinguish the value of sounds. 2nd. Since the signals can only take place when the transmitted currents are in the same direction, two wires must be employed in order to exchange messages on each side.

He surmounted the first difficulty by providing the receiver with an instrument which he called the vibrating contact breaker, and which registered automatically the sounds produced. This contact breaker was placed in the circuit of a local battery, which could work a Morse instrument under certain conditions. When the sounds emitted by the instrument did not correspond with those for which it had been tuned, the contact breaker had no effect on the telegraphic instrument: it only acted when the sounds were those which were to be interpreted, and its action necessarily corresponded to the length of the sounds.

Mr. Bell adds that he applied the system to electro-chemical telegraphs; but we need not dwell on this part of the invention, since, as we have said, it is no longer his special study.

System of M. Lacour of Copenhagen.--M. Lacour's system was patented on the 2nd September, 1874, but his experiments were commenced on the 5th June of the same year. Since M. Lacour believed that the vibrations would be imperceptible on long lines, his first attempts were made on a somewhat short line; but in November 1874 fresh experiments were made between Fredericia and Copenhagen on a line 225 miles in length, and it was ascertained that vibratory effects could be easily transmitted, even under the influence of a rather weak battery.

[Illustration: FIG. 59.]

In M. Lacour's system, the sending instrument is a simple tuning-fork, placed in a horizontal position, and one of its arms reacts on a contact breaker, which can produce precisely the same number of discharges of currents as there are vibrations of the

tuning-fork. If a Morse manipulator is inserted in the circuit, it is evident that if it is worked so as to produce the dots and dashes of the Morse alphabet, the same signals will be reproduced at the opposite station, and the signals will be manifested by long and short sounds, if an electro-magnetic receiver is connected with the circuit. This sender is shown fig. 59.

Fig. 60 represents M. Lacour's receiver. It consists of a tuning-fork F made of soft iron, not of steel like the sending tuning-fork, and each of its branches is inserted in the bobbin of an electro-magnetic coil C C; two distinct electro-magnets M M react close to the extremities of the fork, in such a way that the polarities developed on the two branches of the fork under the influence of the coils C C should be of contrary signs to those of the electro-magnets M M.

[Illustration: FIG. 60.]

If this double electro-magnetic system is inserted in a line circuit, it follows that, for each discharge of the transmitted current, a corresponding attraction of the branches of the tuning-fork will take place, and consequently there will be a vibration, producing a sound, if the discharges are numerous. This sound will naturally be short or long in proportion to the duration of the sender's action, and it will be the same as that of the tuning-fork in that instrument. Again, if one branch of the tuning-fork reacts on a contact P inserted in the circuit of the local battery communicating with a Morse receiver, traces will be produced on this receiver of length varying with the duration of the sounds, for the Morse electro-magnet will be so quickly affected by the successive breaks in the current that its armature will remain stationary throughout each vibration. 'I have not yet been able,' said M. Lacour in an address delivered before the Danish Academy of Science in 1875, 'to calculate the time necessary for the production of definite vibrations in the tuning-fork. Different factors have to be considered, but experiment has shown that the time which elapses before the local circuit is broken is such a small fraction of a second as to be almost inappreciable, even when the current is very weak.

'Since intermittent currents only affect a tuning-fork on condition that it vibrates in unison with the one which produces them, it follows that if a series of sending tuning-forks, tuned to the different notes of the scale, is placed at one end of a circuit, and if a similar series of electro-magnetic tuning-forks, in exact accordance with the first, is placed at the other end of the circuit, the intermittent currents transmitted by the sending tuning-forks will be added to each other without becoming confused, and each of the receiving tuning-forks will only be affected by the currents emitted by the tuning-fork in unison with it. In this way the combinations of elementary signals representing a word may be telegraphed simultaneously.'

M. Lacour enumerates the ways in which this system may be applied as follows: 'If the keys in connection with the sending tuning-forks are placed side by side, and are lowered in succession, or two or three together, it will be enough to play on the keys as on a musical instrument, in order that the air may be heard at the receiving station, or the signals transmitted simultaneously may each belong to a different message. This system will therefore allow the furthest station on a line to communicate with one or several intermediate stations, and _vice versa_, without disturbing the communication at other stations. In this way two stations can exchange signals, unperceived by the rest. The power of sending many signals at once affords a good means of improving the autographic telegraph. In the instruments now in use, such as those of Caselli and D'Arlincourt, there is only one tracing stylus, and this stylus must pass over the whole surface of the telegram in order to obtain a copy of it, but with the telephone a certain number of styli may be placed side by side in the form of a comb, and this comb need only be drawn in a certain direction to pass over the surface of the telegram. In this way a more faithful copy will be obtained in a shorter time.'

M. Lacour also observes that his system possesses a merit already pointed out by Mr. Varley, namely, that the instruments permit the passage of ordinary currents without revealing their presence, whence it follows that the accidental currents which often disturb telegraphic transmissions will have no effect on these systems.

M. Lacour began without applying an electro-magnetic system to his instrument in order to maintain the movement of the tuning-fork, but he soon saw that this accessory was indispensable, and he made the tuning-forks themselves electro-magnetic. It also occurred to him to convert the transmitted currents into pulsatory currents by inserting an induction coil in the circuit, which was also done by Mr. Elisha Gray. Finally, in order to obtain the immediate action of the tuning-forks and the immediate cessation of their action, he constructed them so as to reduce their inertia as much as possible. This was effected by inserting the two branches of the tuning-fork in the same coil and by lengthening its handle, and turning it back so that it might pass through a second coil, dividing into two branches and embracing the two vibrating branches, but without touching them. When a current traverses both coils, it produces, in the kind of horseshoe magnet formed by the two systems, opposite polarities which provoke a double reaction in the vibrating branches--a reaction by repulsion exerted by the two branches in virtue of the same polarity, and a reaction by attraction by the other two branches in virtue of their opposite polarities; and this double action is repeated by the

movements of a contact breaker applied to one of the vibrating branches of the tuning-fork.

[Illustration: FIG. 61.]

Mr. Elisha Gray's System.--According to the system originally patented, each sender, represented fig. 61, consists of an electro-magnet M M resting below a small copper tablet B S, in such a way that its poles pass through this tablet and are on a level with its upper surface. A steel plate A S is fixed above these poles; its tension can be regulated by means of a screw S; and another screw _c_ is placed on the plate, and is in electric communication with a local battery R′ by means of a Morse key. Below the plate A S there is a contact _d_ connected with the line wire L; this contact is met by the plate at the moment of its attraction by the electro-magnet, and breaks the current of a line battery P, which acts on the receiver of the opposite station. Finally, the electric communication established between the local battery R′ and the electro-magnet, as may be seen in the figure, produces vibrations in the steel plate A S at each lowering of the key, as in the case of ordinary vibrations--vibrations which, with a suitable tension of the plate and a given intensity of the battery R′, can produce a definite musical note. Moreover, since at each vibration the plate A S meets the contact, discharges of the line current take place through the line L, and react on the receiving instrument, causing it to reproduce exactly the same vibrations as those of the sending instrument.

[Illustration: FIG. 62.]

The receiving instrument represented fig. 62 exactly resembles the one we have just described, except that there is no contact _d_ below the vibrating plate A S, and the contact _c_, instead of communicating with the line wire, is in electric connection with a register E and a local battery P. It follows from this arrangement that when the plate A S vibrates under the influence of the broken currents passing through the electro-magnet M M, similar vibrations are sent through the register; but if the electro-magnetic organ of this register is properly regulated, these vibrations can only produce the effect of a continuous current, and hence the length of the traces left on the instrument will vary with the duration of the sounds produced. In this way the registration of the dashes and dots which constitute the signs of the Morse vocabulary will be effected.

If it is remembered that the plate A S vibrates under the influence of electro-magnetic attractions more readily in proportion to their approximation in number to the vibrations corresponding to the fundamental sound it can emit, it becomes clear that if this plate is tuned to the same note as that of the corresponding instrument, it will be rendered peculiarly sensitive to the vibrations transmitted by the sender, and the other vibrations which may affect it will only act faintly. Moreover, a resonator placed above the plate will greatly increase this predisposition; so that if several systems of this kind, tuned to different notes, produce simultaneous transmissions, the sounds corresponding to the different vibrations will be in a certain sense selected and distributed, in spite of their combination, into the receivers for which they are specially adapted, and each of them may retain the traces of the sounds emitted by adding the register, which may be so arranged as to act as an ordinary Morse receiver. Mr. Gray states that the number of sending instruments and independent local circuits may be equal to that of the tones and semitones of two or more octaves, provided that each vibrating plate be tuned to a different note of the scale. The instruments may be placed side by side, and their respective local keys, arranged like the keys of a piano, will make it easy to play an air combining notes and chords; there may also be an interval between the instruments, which may be sufficiently far from each other to allow the employés to work without being distracted by sounds not intended for them.

In a new arrangement, exhibited at the Paris Exhibition, 1878, Mr. Gray considerably modified the way of working the various electro-magnetic organs which we have just described. In this case, the plates consist of tuning-forks with one branch kept in continual vibration at both stations, and the signals only become perceptible by intensifying the sounds produced. This arrangement follows from the necessity of keeping the line circuit always closed for multiple transmissions of this nature, so as to react with pulsatory currents, which are alone able, as we have already seen, to retain the individual character of several sounds simultaneously transmitted.

[Illustration: FIG. 63.]

Under these conditions, the sender consists, as we see (fig. 63), of a bar tuning-fork, _a_, which is grooved for the passage of a runner, heavy enough to tune the fork to the desired note, and it oscillates between two electro-magnets _e_ and _f_ and two contacts I and G. The difference of resistance in the electro-magnets is very great: in the one _f_ the resistance is equal to 2¾ miles of telegraphic wire, in the other it does not exceed 440 yards. When electric communication is established as we see in the figure, the following effect takes place. Since the current of the local battery through the two electro-magnets is broken by the rest-contact of the Morse key H, the plate _a_ is subject to two contrary actions; but since the electro-magnet _f_ has more turns

than the electro-magnet _e_, its action is preponderant, and the plate is attracted towards _f_, and produces a contact with the spring G, which opens a way of less resistance for the current. Since the current then passes almost wholly through G, _b_, 1, 2, B, the electro-magnet is now able to act; the plate _a_ is then attracted towards _e_, and, by producing a contact on the spring I, it sends the current of the line B P through the telegraphic line, if the key H is at the same time lowered on the sending contact: if not, there will be no effect in this direction, but since the plate _a_ has left the spring G, the first effect of attraction by the electro-magnet _f_ will be repeated, and this tends to draw the plate again towards _f_. This state of things is repeated indefinitely so as to maintain the vibration of the plate, and to send out signals corresponding with these vibrations whenever the key H is lowered. The elastic nature of the plate makes these vibrations more easy, and it ought also to be put in mechanical vibration at the outset.

The receiver, represented fig. 64, consists of an electro-magnet M, mounted on a sounding-box C, and having an armature formed by a tuning-fork L L firmly buttressed on the box by a cross bar T. There is a runner P on the armature, sliding in a groove, which makes it possible to tune the vibrations of the tuning-fork to the fundamental note of the sounding-box C, which is so arranged as to vibrate in unison with it. Under these conditions, the box as well as the tuning-fork will act as an analyser of the vibrations transmitted by the currents, and may set the register at work by itself reacting on a breaker of the local current. To obtain this result, a membrane of gold-beater's skin or parchment must be stretched before the opening of the box, and a platinum contact must be applied to it, so arranged as to meet a metallic spring connected with any kind of register or a Morse instrument, when the membrane vibrates. As, however, in America the messages are generally received by sound, this addition to the system is not in use.

[Illustration: FIG. 64.]

The instrument is not only regulated by the runner P, but also by a regulating screw V which allows the electro-magnet M to be properly adjusted. The regulating system is made more exact by the small screw V, and the instrument is connected with the line by the binding screw B. Of course this double arrangement is necessary for each of the sending systems.

As I have already said, seven different messages might theoretically be sent at once in this way, but Mr. Gray has only adapted his instrument for four; he has, however, made use of the duplex system, which allows him to double the number of transmissions, so that eight messages may be sent at the same time, four in one direction, and four in another.

Mr. Hoskins asserts that this system has been worked with complete success on the lines of the Western Union Telegraph Company, from Boston to New York, and from Chicago to Milwaukee. Since these experiments were made, fresh improvements have rendered it possible to send a much larger number of messages.

Mr. Gray has also, aided by Mr. Hoskins, devised a system by which telephonic messages may be sent on a wire previously used for Morse instruments. Mr. Varley had already solved this problem, but Mr. Gray's system seems to have produced important results, and has therefore a claim to our attention. We do not, however, describe it here, since it is not within the lines marked out for us, and those who are interested in the subject will find all the necessary details in a paper inserted in the 'Journal of the Society of Telegraphic Engineers, London,' vol. vi.

Mr. Varley's System.--This system is evidently the earliest in date, since it was patented in 1870, and the patent describes the principle of most of the arrangements which have since been adopted by Messrs. Lacour, Gray, and Bell. It is based upon the use of his own musical telephone, which we have already described, but with some variations in its arrangement, which make it somewhat like the Reiss system.

It was Mr. Varley's aim to make his telephone work in conjunction with instruments with ordinary currents, by the addition of rapid electric waves, incapable of making any practical change in the mechanical or chemical capacity of the currents which serve for the ordinary signals, yet able to make distinct signals, perceptible to the ear and even to the eye. He says: 'An electro-magnet offers at first a great resistance to the passage of an electric current, and may consequently be regarded as a partially opaque body with respect to the transmission of very rapid inverse currents or of electric waves. Therefore, if a tuning-fork, or an instrument with a vibrating plate, tuned to a given note, be placed at the sending station, and so arranged as to be kept in constant vibration by magnetic influence, the current which acts upon it must be passed into two helices placed one above the other so as to constitute the primary helix of an induction coil: in this way it will be possible to obtain in two distinct circuits two series of rapidly broken currents, which will correspond to the two directions of the vibrations of the tuning-fork, and we shall also have the induced currents produced in the secondary helix by these currents, which may act on a third circuit. This third circuit may be placed in connection

with a telegraphic line previously used by an ordinary telegraphic system, if a condenser is applied to it, and in this way two different transmissions may be obtained simultaneously.'

[Illustration: FIG. 65.]

Fig. 65 represents the arrangement of this system. D is the vibrating plate of the tuning-fork designed to produce the electric contacts necessary to maintain it in motion. These contacts are at S and S′, and the electro-magnets which affect it are at M and M′. The induction coil is at I′, and the three helices of which it is composed are indicated by the circular lines which surround it. There is a Morse manipulator at A, another at A′, and the two batteries which work the system are at P and P′. The condenser is at C, and the telephone is at the end of the line L.

When the vibration of the plate D tends to the right, and the electric contact takes place at S′, the current of the battery P′, after traversing the primary helix, reaches the electro-magnets M M′, which give it an impulse in the contrary direction. When, on the other hand, it tends to the left, the current is sent through the second primary circuit, which will be balanced by the first. Consequently there will be a series of reversed currents in the induced circuit corresponding to the key A′, which will alternately charge and discharge the condenser C, thus sending into the line a corresponding series of electric undulations which will react on the telephone placed at the end of the line; and as the duration of the transmitted currents will vary with the time that the key A′ is lowered, a correspondence in the Morse code may be obtained in the telephone, while another correspondence is exchanged with the key A and the ordinary Morse receivers.

In order to render the vibratory signals visible, Mr. Varley proposes to use a fine steel wire, stretched through a helix and facing a narrow slit, to reproduce the vibrations. A light, which is intercepted by the wire, is placed behind the slit. As soon as a current passes, the wire vibrates and the light appears. A lens is placed so as to magnify the image of the luminous slit, and project it on a white screen while the wire is in vibration.

VARIOUS USES OF THE TELEPHONE.

Its domestic application.--We have seen that telephones may be used with advantage in public and private offices: they can be set up at a much less expense than acoustic tubes, and in cases where the latter would never be employed. With the aid of the calls we have described, they offer the same advantages, and the connection between the instruments is more easily concealed. The difference of price in establishing them is in the ratio of one to seven.

For this purpose electro-magnetic telephones are evidently the best, since they require no battery and are always ready to work. They are already in use in many Government offices, and it is probable that they will soon be combined with electric bells for the service of hotels and of large public and private establishments: they may even be used in private houses for giving orders to servants and porters, who may thus save visitors from the fatigue of a useless ascent of several storeys.

In factories, telephones will certainly soon replace the telegraphic communication which has already become general. They may not only be used for ordinary messages, but to call for help in case of fire, and they will become an integral part of several systems already established for this purpose.

In countries which have free telegraphic communication, the telephone has already replaced in great measure the private telegraph instruments which have hitherto been in use; and if the same privilege is extended to France, no other mode of correspondence will be used.

Its application to telegraphic service.--The advantage to be derived by the telegraphic service from the telephone is rather limited, since, as far as the speed of transmission is concerned, it is of less value than many of the telegraphic instruments now in use, and the messages which it produces cannot be registered. Yet in municipal offices not overburdened with messages they offer the advantage of not requiring a trained service. On longer lines their use would be of little value. The 'Berne Telegraphic Journal' has published some interesting remarks on this subject, of which the following is a summary.

1st. In order to send a message with the special advantages of the system, the sender ought to be able to address his correspondent without the intervention of an official. Those who are acquainted with the network of wires know this to be impossible. Intermediate offices for receiving messages are essential, and the public cannot be admitted to those set apart for sending and receiving; consequently the sender must deliver a written message.

2nd. If the message is written, the chief advantage of the instrument is lost, since it must be read and uttered aloud, which could not be done if expressed in a language with which the employés were unacquainted.

3rd. The instruments now in use at the telegraph offices can transmit messages more quickly than if they were spoken.

In Germany, however, a telephone service has been established in several telegraph offices, and its possible advantages are enumerated as follows in the official circular which created it:

‘The offices which will be opened to the public for the service of telephonic messages in Germany will be regarded as independent establishments; yet they will be in connection with the ordinary telegraph offices, which will undertake to send telephonic messages through their wires.

‘The transmission will take place as follows: The sending office will request the receiving office to prepare the instrument; as soon as the tubes are adjusted, the sending office will give the signal for despatching the verbal message.

‘The sender must speak slowly and clearly, without raising his voice; each syllable must be distinctly pronounced; the final syllables especially must be well articulated, and there must be a pause after each word, in order to give the receiver time to write it down.

‘When the telegram has been received, the employé at the receiving office must verify the number of words; then he must repeat through the telephone the whole message without pausing, so as to make sure that there is no mistake.

‘In order to ensure secrecy, the telephones are placed apart, where persons unconnected with the service cannot hear the verbal message, and the employés are forbidden to reveal to anyone the names of the correspondents.

‘The charge for telephonic messages, as for the ordinary telegraphic services, is at the rate of so much a word.’

The use of the telephone has also been suggested for verifying the perfect junction of telegraphic wires. It is certain that, if the junction is complete, no abnormal sounds will be heard, or only those which result from accidental currents; but if the junction is bad, the imperfect contacts which take place produce variations in electric intensity which are translated into the more or less marked sounds observed in the telephone.

M. Mauborgne, the electrician attached to the Northern Railway of France, has lately used the telephone instead of the galvanometer to ascertain the condition of the circuits in correspondence with the instruments in use for electric signals. The reactions produced on the galvanometer needle by the pieces of iron which are placed at the sides of the railway often make its indications uncertain, and a strong wind produces irregular movements in the instrument which interfere with observations. It was also necessary to place the galvanometer with due regard to the points of the compass, and to wait for the needle to settle, which involved loss of time. The operation is easily accomplished with the telephone, since the strokes of the call-bell are distinctly reproduced; it is made to ring by working the contacts which need verification, and in the same way the condition of the battery can be ascertained.

Application to military purposes.--Since the telephone was invented, numerous experiments have been made in different countries to ascertain whether it would be of use in military operations. These experiments have hitherto been only moderately satisfactory, on account of the noise inseparable from an army, which generally makes it impossible to hear the telephone, and every means of intensifying its sounds has been eagerly sought. It was at first supposed that the discovery of the microphone had solved the problem, and I received many enquiries from military schools on the subject, but I have not been able to see that anything has been gained from this point of view. The telephone is, however, of great use in schools of artillery and rifle practice. Now that firearms carry so far, it has become necessary to be informed by telegraph of the points hit on the target, in order to judge of the accuracy of aim, and for this purpose telegraphic targets were suggested; but telephones are much to be preferred, and they are now used with good effect.

If the telephone is unsuited for the service of the flying telegraph in the field, it may be of great use in the defence of towns, to transmit the orders of the commandant to different batteries, and even for the exchange of correspondence with captive balloons sent to hover over fields of battle.

In spite of the difficulties attending its use, the experiment was made by the Russians in the late war: the cable wire of communication was 500 or 600 yards long, and so light that it could be laid by one man. The ‘Telegraphic Journal’ of March 15, 1878, states that the bad weather did not interfere with the working of the instruments; but the noise made it difficult to hear, and it

was necessary to cover the head with a hood to intercept external sounds. This cannot be considered a satisfactory result, yet the telephone may be of great service to an army by intercepting the enemy's messages: a bold man, provided with a pocket telephone, who placed himself in a retired spot, might divert the current of the enemy's telegraphic wire into his telephone, and get possession of all his despatches, as we saw was the case at Clermont. He might even do this by diverting the current to earth or to a rail of the railway line. These are suggestions for future research, and it is probable that they may some day be turned to practical account.

Its application to the navy.--The telephone may be of the greatest use in naval matters, for the service of electro-semaphores, for island forts and ships at anchor. M. Pollard says that 'experiments made between the Préfecture Maritime at Cherbourg, the semaphores and the forts on the mole, demonstrate the advantage there would be in establishing telephones at these stations, since they would ensure an easy communication between the vessels of a squadron and the land they are approaching. By sinking small cables which come to the surface of the water along mooring chains, and terminate in buoys or cases which remain permanently in the harbour, the ships of war may in this way place themselves in communication with the Préfecture Maritime as they cast anchor, and, by temporarily connecting the vessels together with light cables, the admiral may communicate freely with the whole squadron.'

The telephone has been tried on board ship for transmitting orders, but without success, on account of the noise always going on in a vessel.

The telephone may be usefully applied to the service of submarine torpedoes. We have already seen how it may be applied in connection with the microphone, but it may also be used in firing the torpedoes after the exact position of the enemy's ship has been ascertained from two reconnaissances taken from different parts of the coast.

The telephone, again, makes it possible to verify the condition of torpedoes, and to ascertain if there is any fault in the circuit within the explosives. For this purpose a very weak current has been used, and a galvanometer is not always able to indicate the fault, while the extreme sensitiveness of the telephone will do so in the simplest way.

Captain M'Evoy, of the American Army, suggested a way of ascertaining, while on shore, the condition of torpedoes under water, by connecting the buoys which support them with the land by means of a telephonic line. By inserting, in the buoy which supports the torpedo, metallic disks, so arranged as to vibrate with every movement caused by the waves upon the buoy, a continuous noise will be heard in the telephone, after the circuit has been completed by the metallic disks; and the noise will go on as long as the disks continue to oscillate, and will cease as soon as the buoy is completely covered by the water. When it ceases, therefore, if not affected by some accidental cause, it may be supposed that the enemy's ship is passing over the buoy.

M. Trève, again, has shown that the telephone might be used with advantage for the telegraphic communication between vessels in tow, and M. des Portes has applied it with good effect to diving operations. In this instance, one of the glass panes in the helmet is replaced by a copper plate in which the telephone is framed, so that the diver need only make a slight movement of his head in order to receive or address communications to those in charge of the apparatus. With this system the keels of vessels may be examined, and an account given of their condition, without bringing up the divers, which has hitherto been necessary.

M. de Parville, the able and learned editor of the _Journal Scientifique_ and the science department of the _Journal des Débats_, has suggested a new and interesting application of the telephone. It concerns the possibility of making use of it to determine the precise position of the magnetic meridian, that is, the true direction of the magnetised needle.

For this purpose a Bell telephone is necessary, of which the magnetic core is formed of an iron rod a mètre in length, kept, by a suitable suspension, at nearly the same angle of inclination as a dipping-needle. This rod will be magnetised under the influence of terrestrial magnetism, and the telephone will be able to transmit the sounds produced by some sort of vibrator placed near its mouthpiece. These sounds will be strong in proportion to the degree of magnetisation of the bar; and if the telephone is turned round the horizon, keeping the bar at the same angle of inclination, the sounds transmitted to the receiving telephone will be greatest when the axis of the bar is in the plane of the magnetic meridian, and least when it is at 90°. It will therefore be possible to ascertain from the direction of the axis at the moment when the sounds are no longer heard, the exact inclination of the magnetic needle from north to south, for it will be given by the perpendicular to the line which is followed by the axis of the iron bar at that moment.

It is possible that, with this system, the disturbing influence on the magnetic needle of the mass of iron in iron-plated vessels might be almost destroyed, and a more exact orientation than that of the compass might be obtained. The same process may make it possible to estimate and measure the variations of terrestrial magnetism. M. de Parville has not himself tried to apply this system; but Mr. Blake's experiments, of which we spoke in an early part of this work, make it probable that it might be done with advantage.

Application to industry.--One of the earliest and most important applications of the telephone is that which was first made to the service of mines in England and America in the autumn of 1877. The great length of the galleries is well known, and had already involved the use of the electric telegraph for transmitting orders; but the miners did not understand how to work these instruments, and the service was ill performed. Thanks to the telephone, through which the first corner can send and receive a message, there is no longer any difficulty in the communication between the galleries and the surface of the mine.

The ventilation of mines can also be regulated by the aid of telephones. If one of these instruments is placed near a wheel kept in motion by the air which passes through the ventilating shaft, and another is placed in the inspector's office he can ascertain by the sound if the ventilation is duly carried on, and if the machine works regularly.

Application to scientific research.--M. d'Arsonval's experiments, which we have already mentioned, show that the telephone can be used as an extremely sensitive galvanoscope; but since it can only produce sounds under the influence of broken currents, the circuit on which the experiment is made must be divided at rather close intervals. It has been seen that it is not even necessary to insert the telephone in the circuit: it may be influenced, when at a distance, either immediately or by the induction of the broken current on a circuit placed parallel to the first, and the force of these effects may be increased by the reaction of a core of iron, round which the inducing circuit is wound. The drawback to this system is that the direction of the current is not ascertained, so that it cannot be used as a measuring instrument; but, on the other hand, it is so sensitive, so easy to arrange, and so inexpensive, that it might be of the greatest use as a galvanoscope.

Mr. Warren de La Rue has also made use of the telephone in his researches into the electric discharges of high-tension batteries, in order to follow the different phases of the discharge during the luminous phenomena which it produces. In this way he ascertained that when a condenser is placed in connection with a battery formed of a considerable number of insulated elements, and is gradually discharged through a Geissler tube, a dull and faint sound is heard in the telephone, as long as the stratifications of light appear to be perfectly stable; but the sound becomes considerably stronger, and sometimes even piercing, in proportion to the diffusion of these stratifications, and to their approach to the point of extinction: whence it is shown that the discharge of a battery into tubes in which a vacuum has been made is intermittent.

Mr. Spottiswoode has repeated the same experiments with the discharges of Holtz machines, and with large condensers, and he found that the most piercing sounds produced by the telephone coincided with the greatest development of the stratifications. These sounds, however, sometimes ceased for a moment. It was even possible to ascertain, from the intensity of the sounds produced, the differences of tension which might be manifested in the charge of the condenser and the slackening of the machine's motion, and the differences of intensity in these sounds might in some cases exceed an octave. The fall in the scale generally appeared in half-tones instead of gradually, and the introduction of resistances into the circuit modified the sounds very much: they might even be intensified by approaching the finger to the discharging tube.

From experiments made with the telephone between Calais and Boulogne, it appears that this instrument might be applied with advantage to the science of projectiles. In fact, in some artillery practice which took place on the shore at Boulogne, a telephone was placed close to the gun, and the explosion was heard at a distance of nearly two miles, where the projectile fell. It was possible to estimate its velocity by measuring the lapse of time between the moment when the projectile left the gun, and its fall. This calculation is usually made by observing the flash from the cannon's mouth; but in some cases, as in a fog or in practice at long ranges, the telephone may be usefully substituted for ocular observation. On the field of battle, an observer, provided with a telephone and placed on a hill, might rectify from a distance the aim of his battery, which is generally established in a sheltered and less elevated place.

THE PHONOGRAPH.

Mr. Edison's Phonograph, which has for the last year attracted so much attention, is an instrument which not only registers the different vibrations produced by speech on a vibrating plate, but reproduces the same words in correspondence with the traces registered. The first function of this instrument is not the result of a new discovery. Physicists have long sought to solve the problem

of registering speech, and in 1856 Mr. Leo Scott invented an instrument well known to physicists under the name of Phonautograph, which completely solved the difficulty: this instrument is described in all the more detailed treatises on physics. But the second function of the Edison instrument was not realised nor even mentioned by Mr. Scott, and we are surprised that this able inventor should have regarded Mr. Edison's invention as an injurious act of spoliation. We regret on his own account, since no one has wished to deprive him of the credit he deserves, that he should have published a pamphlet on the subject, couched in terms of such asperity, which proves nothing, and only states facts which were well known to all physicists. If any other person could claim the invention of the phonograph, at least in its most curious property of reproducing speech, it would certainly be M. Charles Cros; for in a sealed paper deposited at the Académie des Sciences, April 30, 1877, he pointed out the principle of an instrument by means of which speech might be reproduced in accordance with the marks traced on a register like that of the phonautograph.[19] Mr. Edison's patent, in which the principle of the phonograph is first indicated, is dated July 31, 1877, and he was still only occupied with the repetition of the Morse signals. In this patent Mr. Edison described a mode of registering these signals by means of indentations traced with a stylus on a sheet of paper wound round a cylinder, and this cylinder had a spiral groove cut on its surface. The tracings thus produced were to be used for the automatic transmission of the same message, by passing it again under a stylus which should react on a current breaker. In this patent, therefore, nothing is said of the registration of speech or of its reproduction; but, as the 'Telegraphic Journal' of May 1, 1878, observes, the foregoing invention gave him the means of solving this double problem as soon as it was suggested to him. If we may believe the American journals, this suggestion soon came, and it was the result of an accident.

In the course of some experiments Mr. Edison was making with the telephone, a stylus attached to the diaphragm pierced his finger at the moment when the diaphragm began to vibrate under the influence of the voice, and the prick was enough to draw blood. It then occurred to him that if the vibrations of the diaphragm enabled the stylus to pierce the skin, they might produce on a flexible surface such distinct outlines as to represent all the undulations produced by the voice, and even that the same outlines might mechanically reproduce the vibrations which had caused them, by reacting on a plate capable of vibrating in the same way as that which he had already used for the reproduction of the Morse signals. From that moment the phonograph was discovered, since there was only a step between the idea and its realisation, and in less than two days the instrument was made and tried.

This is an ingenious story, yet we would rather believe that the discovery was made in a more serious spirit. In fact, such an inventor as Mr. Edison, who had discovered the electro-motograph, and had applied it to the telephone, was already on the way to discover the phonograph, and we think too well of his powers to attach much credit to this American romance. Besides, Mr. Edison was well acquainted with Mr. Scott's phonautograph.

Mr. Edison's phonograph was only patented in January 1877. Consequently, when we look at the principle of the invention, M. Cros undoubtedly may claim priority; but it is a question whether the system described in his sealed paper, and published in the _Semaine du Clergé_, October 8, 1877, would have been capable of reproducing speech. Our doubt seems justified by the unsuccessful attempts of the Abbé Leblanc to carry out M. Cros' idea. When we have to do with such undulating and complex vibrations as those involved in the reproduction of articulate words, it is necessary that the stereotyping should in some sense be effected by the words themselves, and their artificial reproduction will necessarily fail to mark the slight differences which distinguish the delicate combinations of speech. Besides, the movements performed by a point confined to a groove that follows a sinusoidal curve cannot be effected with all the freedom necessary for the development of sounds, and the friction exerted on the two edges of the groove will often be of a nature to stifle them. A distinguished member of the Société de Physique, when I exhibited the phonograph to that society, justly said that Mr. Edison's whole invention consisted in the thin metallic sheet on which the vibrations are inscribed; this sheet permits the movements of the vibrating plate to be directly stereotyped, and thereby the problem is solved. It was necessary to find such an expedient, and it was done by Mr. Edison, who is therefore the inventor of the phonograph.

After M. Cros, and before Mr. Edison, MM. Napoli and Marcel Deprez attempted to make a phonograph, but with so little success that they believed at one time the problem to be insoluble, and threw doubts on Mr. Edison's invention when it was announced to the Société de Physique. They subsequently resumed their labours, and lead us to hope that they may eventually produce a phonograph of more perfect construction than that of Mr. Edison. We shall have more to say on this subject.

In conclusion, the mechanical reproduction of speech was first effected by Mr. Edison, and in so doing he has accomplished one of the most curious and important discoveries of our time, since it has shown that this reproduction was much less complicated than had been supposed. Yet the theoretical consequences of the discovery must not be exaggerated, since I do not consider it by any means proved that our theories on the voice are incorrect. There is in fact a great difference between the reproduction of a sound

which has been uttered, and the mode in which the same sound was produced. The reproduction may be easily effected, as M. Bourseul has remarked, as soon as a mode has been discovered of transmitting the vibrations of air, however complex they may be; but in order to produce the complex vibrations of speech by the voice, several special organs must be exercised--first, the muscles of the throat; secondly, the tongue, the lips, and even the teeth--and for this reason an articulating machine is necessarily very complex.

Surprise was expressed that the speaking machine, which was brought from America two years ago, and exhibited at the Grand Hôtel, Paris, was so extremely complicated, since the phonograph solved the problem in such a simple way. This is because the latter instrument only reproduces speech, while the former utters it, and the inventor of the speaking machine had to employ in his mechanism all the organs which are necessary in our organism for the reproduction of speech. The problem was infinitely more complex, and this invention has not attracted all the attention it deserved. We shall speak of it presently. We must now describe the phonograph and the different applications which have been, or which may be, made of it.

Description of Phonograph, and mode of using it.--The first and best known model of this instrument, which we represent in fig. 66, simply consists of a registering cylinder R, set in motion with the hand by a winch M, before which a vibrating plate is placed, furnished on its face with a telephone mouthpiece E, and on the reverse side with a tracing point. This tracing point, which is seen at _s_ in the section of the instrument given in fig. 68, is not fixed directly on the plate; it rests on a spring _r_, and a caoutchouc pad _c_ is placed between it and the vibrating disk. This pad is formed of the end of a tube which is designed to send the vibrations of the plate to the point _s_ without stifling them. Another pad _a_, placed between the plate L L and the rigid support of the point, moderates in some degree these vibrations, which, without this precaution, would generally be too powerful.

[Illustration: FIG. 66.]

The cylinder, of which the axis A A (fig. 66) is cut at one end like a screw, to enable it to make a lateral progressive movement simultaneously with the rotatory movement effected on itself, has on its surface a narrow screw-thread coinciding with that of the axis, and when the tracing point is inserted, it is able to pass along it for a distance corresponding to the time occupied in turning the cylinder. A sheet of tinfoil or of very thin copper is carefully applied to the surface of the cylinder, and it should be slightly pressed down upon it, so as to show a faint tracing of the groove, and to allow the point of the vibrating disk to be placed in a proper position. The point rests on the foil under a pressure which must be regulated, and for this purpose, as well as to detach the cylinder when it is desired to place or take away the tinfoil, there is the articulated system S N which sustains the support S of the vibrating disk. This system consists of a jointed lever in which there is a nut screw for the screw R. The handle N at the end of the lever allows the tracing system to be turned aside when the screw R is loosened. In order to regulate the pressure of the tracing point on the sheet of tinfoil, it is enough to turn the screw R loosely in its socket, and to tighten it as soon as the right degree of pressure is obtained.

This is the simple system by which speech can engrave itself on a plate in durable characters, and it works in the following manner.

[Illustration: FIG. 67.]

The speaker stands before the mouthpiece E, as before a telephone or an acoustic tube, and speaks in a strong, emphatic voice, with his lips pressed against the walls of the mouthpiece, as we see in fig. 67; at the same moment he turns the handle of the cylinder, which is provided with a heavy fly-wheel in order that the movement may be regular. Influenced by the voice, the plate L L begins to vibrate, and sets the tracing point at work, which presses on the tinfoil at each vibration, and produces a furrow whose depth varies along its course in correspondence with the unequal vibrations of the disk. The cylinder which moves at the same time presents the different parts of the groove of which we have spoken to the tracing point in succession; so that when the spoken sentence comes to an end, the design which has been pricked out, consisting of a succession of reliefs and depressions, represents the registration of the sentence itself. The first part of the operation is therefore accomplished, and by detaching the sheet from the instrument the words may be put away in a portfolio. We have now to see how the instrument is able to reproduce what has been so easily inscribed.

For this purpose it is only necessary to repeat the process, and the identical effect will be reproduced in an inverse sense. The tracing stylus is replaced at the end of the groove it has already traversed, and the cylinder is again set in motion. When the engraved track passes again under the point, it has a tendency to raise it and to impart to it movements which must necessarily be the repetition of those which first produced the tracing. The vibrating plate is obedient to these movements, and begins to vibrate, thus producing the same sounds, and consequently the same words; yet since there is necessarily a loss of power in this double

transformation of mechanical effects, the speaking tube C is attached to the mouthpiece E in order to intensify the effects. Under these conditions the words reproduced by the instrument may be heard in all parts of a hall, and it is startling to hear this voice--somewhat shrill, it must be admitted--which seems to utter its sentences from beyond the grave. If this invention had taken place in the middle ages, it would certainly have been applied to ghostly apparitions, and it would have been invaluable to miracle-mongers.

[Illustration: FIG. 68.]

As the height of the notes of the musical scale depends on the number of vibrations effected by a vibrating substance in a given time, speaking will be reproduced in a tone of which the pitch will depend on the velocity of rotation given to the cylinder on which the tinfoil is wound. If the velocity is the same as that which was used in registration, the tone of the words reproduced is the same as that in which they were uttered. If the velocity is greater, the tone is higher; if less, the tone is lower; but the accent of the speaker may always be recognised. Owing to this peculiarity the reproduction of songs is nearly always defective in instruments turned by the hand; they sing out of tune. This is not the case when the instrument is moved by a well-regulated system of clockwork, and in this way a satisfactory reproduction of a duet has been obtained.

The words registered on tinfoil can be often reproduced; but the sounds become fainter and more indistinct at each repetition, since the tracings in relief are gradually effaced. The reproduction on copper is more successful, but if intended to be permanent the sheets must be stereotyped, and in this case the instrument must be differently arranged.

An attempt has been made to obtain speech from the phonograph by taking the words registered inversely to their true direction. In this way the sounds obtained were necessarily quite unlike the words uttered; yet Messrs. Fleeming Jenkin and Ewing have observed that not only are the vowels unchanged by this inverse action, but consonants, syllables, and even whole words may be reproduced with the accent they would have if spoken backwards.

The sounds produced by the phonograph, although fainter than those of the voice which produced the registered tracing, are strong enough to react on the ordinary string telephone, and even on a Bell telephone; and as in this case the sounds do not go beyond the instrument, and can only be heard by the person who is using it, it is easy to ascertain that the sound has not been produced by trickery.

Mr. Edison presented his phonograph to the Académie des Sciences through me, March 11, 1878, and when his agent, M. Puskas, caused the wonderful instrument to speak, a murmur of admiration was heard from all parts of the hall--a murmur succeeded by repeated applause. A letter appeared in the newspapers from one of the persons present, in which he said that ‘the learned Academy, generally so cold, had never before abandoned itself to such enthusiasm. Yet some members of a sceptical turn of mind, instead of examining the physical fact, ascribed it to moral causes, and a report soon ran through the room which seemed to accuse the Academy of having been mystified by a clever ventriloquist. Certainly the spirit of ancient Gaul is still to be found among the French, and even in the Academy. One said that the sounds emitted by the instrument were precisely those of a ventriloquist. Another asked if the movements of M. Puskas’ face and lips as he turned the instrument did not resemble the grimaces of a ventriloquist. A third admitted that the phonograph might emit sounds, but believed that it was much helped by the manipulator. Finally, the Academy requested M. du Moncel to try the experiment, and as he was not accustomed to speak into the instrument, it was unsuccessful, to the great joy of the incredulous. Some members of the Academy, however, desiring to ascertain the real nature of the effects, begged M. Puskas to repeat the experiments before them in the secretary’s office under such conditions as they should lay down. M. Puskas complied with this request, and they were absolutely satisfied with the result. Yet others remained incredulous, and it was necessary that they should make the experiment for themselves before they accepted the fact that speech could be reproduced in so simple a way.’

The anecdote I have just related cannot be interpreted to the discredit of the Académie des Sciences, since it is especially bound to preserve the true principles of science intact, and only to accept startling facts after a careful examination. Owing to this attitude, all which emanates from the Academy can be received with complete confidence; and we cannot approve too highly of reserve which does not give way to the first impulse of enthusiasm and admiration.

The failure of my experiment at the Academy was simply due to the fact that I spoke at too great a distance from the vibrating disk, and that my lips did not touch the sides of the mouthpiece. Some days later, at the request of several of my colleagues, I made repeated trials of the instrument, and I soon succeeded in making it speak as well as the supposed ventriloquist; but I learned at the same time that practice is necessary to ensure success. Some words are reproduced more readily than others; those which include

many vowels and many _r_’s come out better than those which abound in consonants, and especially in _s_’s. It is therefore not surprising that, even in the case of an experienced manipulator like Mr. Edison’s agent, some of the sentences uttered by him are more audible than others.

The simultaneous repetition of several sentences in different languages by registering one over the other is one of the most surprising effects of the phonograph. As many as three different sentences have been obtained; but in order to distinguish them through the confused sounds which result from placing one over the other, it is necessary that different persons, giving special attention to a particular sentence, should thus separate them and understand their sense. Vocal airs may, in the same way, be registered over the word tracings, and in this case it is more easy to distinguish them.

There are several models of phonographs. The one represented in fig. 66 has been chiefly used for public experiments, but there is a small model, generally sold to the public, in which the cylinder is much longer, and serves at once for register and fly-wheel. This instrument gives good results, but can only be used for short sentences. In this model, as indeed in the other, the words are more easily registered by fastening a small tube in the form of a prolonged speaking-trumpet to the mouthpiece; the vibrations of the air are thus concentrated on the vibrating disk, and act with greater energy. The tenuity of the vibrating disk adds to the efficiency of the instrument, and the tracing point may be fitted directly to this disk.

[Illustration: FIG. 69.]

I need not describe particularly the phonograph which acts by clockwork. The instrument resembles the one represented fig. 66, except that it is mounted on a rather high table, to give room for the descent of the weight which moves the clockwork; the mechanism is applied directly to the axis of the cylinder, supplying the place of the winch, and is regulated by a small fly-wheel. The wheel used in an English system has been adopted, but we prefer that of M. Villarceau, which has small wings.

Since it is always difficult to fit the tinfoil to the cylinder, Mr. Edison has tried, with good success, to obtain the tracing on a plane surface of tinfoil, by means of the arrangement represented fig. 69. In this new model, the plate on which the tin or copper sheet is to be applied has a spiral grooving, of which one end corresponds to the centre of the plate, and the other to its outer edges. The plate is set in motion by a powerful system of clockwork, of which the velocity is regulated with reference to the length of the turns of the spiral. The vibrating disk is arranged as in the former instrument, and is placed above this plate; the tracing point may, by means of a movement of progression imparted to the system, follow the spiral groove from the centre of the plate to its circumference.

It must not be supposed that all the tinfoil used for phonographic registration is equally good. The foil must be of a definite thickness, and combined with a definite amount of lead. That which is used for wrapping chocolate, and indeed all foil of French manufacture, is too thin and too exclusively made of tin to produce good results, and M. Puskas was obliged to import some from America to continue his experiments. The relative proportion of lead and tin has not yet been defined, and the selection of foil has been made empirically; but as the use of the phonograph becomes more general, this proportion must be ascertained, and it may easily be done by analysing the composition of the foil which gives the best results.

[Illustration: FIG. 70.]

The arrangement of the tracing point is also of much importance for the successful action of the phonograph. It must be very slender and very short (not exceeding a millimètre in length), so as to register distinctly the smallest vibrations of the vibrating disk without deviating from the normal direction of the cylinder, which might be the case, if it were long, on account of the unequal friction exerted on the tinfoil. It must also be made of a metal which has no tendency to tear the metallic sheet. Iron appears to combine most of the conditions demanded.

The phonograph is still in its infancy, and it is probable that it may soon be enabled to register speech without the necessity of speaking into a mouthpiece. According to the newspapers, Mr. Edison has already discovered a way of collecting, without the aid of an acoustic tube, the sounds uttered at a distance of three or four feet from the instrument, and of printing them on a metallic sheet. From this there is only a step to the power of inscribing a speech uttered in a large hall at any distance from the phonograph; and if this step is taken, phonography may be substituted with advantage for shorthand. We add in a note the instructions given by M. Roosevelt to the purchasers of phonographs, so as to enable them to work the instrument.[20]

Considerations on the theory.--Although the explanation we have given will make the effects of the phonograph intelligible, it leads to a curious question which has greatly interested physicists--namely, how it is that the tracing made on so yielding a surface

as tin can, when retraced by the stylus, of which the rigidity is relatively great, produce a vibratory movement without being completely destroyed. To this we reply that the retracing is effected with such extreme rapidity that the effects of active force which are developed only manifest themselves locally, and that under these conditions the mechanical effects exerted are as energetic in soft as in hard substances. The curious experiment, related in so many books on physics, must be remembered, of a plank pierced when a candle serves as the projectile of a gun. The various accidents caused by the discharge of paper waddings must also be remembered. Under such conditions the motion imparted to the molecules which receive the shock has not time to be transmitted to the whole mass of the substance to which they belong, and these molecules are compelled to separate from it, or at any rate to produce, when the substance is capable of vibration, a centre of vibration which diffuses waves throughout its surface, and produces sounds.

Several scientific men, among others Messrs. Preece and Mayer, have carefully studied the form of the tracing left by the voice on the tinfoil of the phonograph, and they observe that it greatly resembles the outline of the singing flames so well shown by Herr Koenig's instruments. Mr. Mayer wrote on this subject in the 'Popular Science Monthly Review' of April 1878.

He said that he had been successful in reproducing a splendid tracing on smoked glass, which gave in profile the outline of the vibrations of sound registered on the tinfoil with their varying curves. For this purpose he fastened to the spring support of the tracing point of the phonograph a slender rod, terminating in a point, which pressed obliquely against the plate of smoked glass, and, since the latter was in a vertical position, a movement imparted to the rod enabled it to produce a sinusoidal tracing. By this arrangement, when the phonograph was at work, two systems of tracings were produced at the same moment, of which one was the profile of the other.

Mr. Mayer had not, at the time he wrote, been long enough in possession of the instrument to make many experiments with it, but from a study of some of its curves it appeared to him that the registered outlines bore a strong resemblance to those of Koenig's singing flames.

[Illustration: FIG. 71.]

Fig. 71 represents the tracing which corresponds to the letter _a_ when pronounced as in _bat_, in the three systems of registration. That corresponding to line A is an enlarged reproduction of the tracing left on the tinfoil; that corresponding to line B represents its profile on the sheet of smoked glass. Finally, line C shows the outline of Koenig's singing flames, when the same sound is produced quite close to the membrane of the register. It must be quite close, since the form of the tracing produced by a pointer attached to a vibrating membrane, when influenced by composite sounds, depends on the distance intervening between the membrane and the source of sound, and an infinite variety in the form of the tracing may be obtained by modifying the distance. In fact, when this distance is increased, the waves of sound which result from composite sounds react on the membrane at different moments of their emission. For example, if the composite sound is formed of six harmonics, the displacement of the source of vibration from the first harmonic by ¼ the length of a wave will respectively remove the second, third, fourth, fifth, and sixth harmonics ½, ¾, 1, 1¼, 1½ the length of a wave, and consequently the outline resulting from the combination of waves will no longer be the same as it was before the displacement of the source of sound, although the perception of the sounds remains the same in both cases. This principle is clearly demonstrated by Koenig's instrument, by lengthening and shortening an extensible tube, inserted between the resonator and the vibrating membrane, which is placed close to the flame; and this explains the disagreement of physicists as to the composition of vocal sounds which they have analysed by means of the singing flames.

Mr. Mayer adds that these facts further show that we cannot hope to read the impressions and tracings of the phonograph, which not only vary with the nature of the voice, but also with the different moments at which the harmonics of the voice are emitted, and with the relative differences in the intensities of these harmonics.

Notwithstanding this assertion, we reproduce (fig. 72) an extremely curious tracing sent to us by Mr. Blake, which represents the vibrations produced by the words 'Brown, University: how do you do?' They were photographed by means of an index fastened to a vibrating disk on which a ray of light was thrown. The word 'how' is particularly remarkable for the combined forms of the inflections of the vibrations.

Recent experiments seem to show that the more the vibrating membrane of the phonograph resembles the human ear in its construction, the better it repeats and registers the sound vibrations: it should be stretched, as far as possible, in the same way as the tympanum is stretched by the hammer of the ear, and moreover it should have the same form, since the vibrations of air are in this case much more effective.

[Illustration: FIG. 72.]

Mr. Edison considers that the size of the opening of the mouthpiece has considerable influence on the distinct articulation of speech. When the sounds are pronounced before the whole surface of the diaphragm, some hissing sounds are lost. They are, on the contrary, intensified when these sounds reach the diaphragm through a narrow orifice with sharp rims. If the opening is toothed on its flattened rims, the hissing consonants are delivered more clearly. Speech is reproduced more perfectly when the mouthpiece has a covering of some thickness, so arranged as to deaden the sounds arising from the friction of the tracing point on the tin.

Mr. Hardy has rendered the registration of phonographic tracings more easy by adding a small ebonite tube, resembling the mouthpiece of a wind instrument, to the mouthpiece of the phonograph.

USES OF THE PHONOGRAPH AND ITS FUTURE.

Mr. Edison has lately published in the 'North American Review' of May-June 1878 an article on the future of the phonograph, in which he himself discusses the different applications which may be made of this instrument. Without sharing all his anticipations, which appear to us to be very premature, we think that some extracts from his paper may be interesting.

'In order to furnish a basis on which the reader may take his stand ... a few categorical questions and answers are given upon the essential features of the principle involved.

'1. Is a vibrating plate or disk capable of receiving a complex motion which shall correctly represent the peculiar property of each and all the multifarious vocal and other sound waves?

'The telephone answers affirmatively.

'2. Can such complex movement be transmitted from such plate by means of a single embossing point attached thereto, to effect a record upon a plastic material, by indentation, with such fidelity as to give to such indentations the same varied and complex form? And if so, will this embossing point, upon being passed over the record thus made, follow it with such fidelity as to transmit to the disk the same variety of movement, and thus effect a restoration or reproduction of the vocal or other sound waves, without loss of any property essential to producing on the ear the same sensation as if coming direct from the original source?

'The answer to this may be summed up in a statement of the fact that ... the writer has at various times during the past weeks reproduced these waves with such degree of accuracy in each and every detail as to enable his assistants to read, without the loss of a word, one or more columns of a newspaper article unfamiliar to them, and which were spoken into the apparatus when they were not present. The only perceptible loss was found to be in the quality of the utterance, a non-essential in the practical application of the instrument. Indeed, the articulation of some individuals has been perceptibly improved by passage through the phonograph, the original utterance being mutilated by some imperfection of lip and mouth formation, and these mutilations corrected or eliminated by the mechanism of the phonograph.[21]

'3. Can a record be removed from the apparatus on which it was made, and replaced upon a second without mutilation or loss of effective power to vibrate the second plate?

'This is a mere mechanical detail, presenting no greater obstacle than having proper regard for the perfect interchangeableness of the various working parts of the apparatus--not so nice a problem as the manufacture of the American watch.

'4. What as to the facility of placing and removing the second sheet, and as to its transportation by mail?

'But ten or fifteen seconds suffice for such placing or removing. A special envelope will probably be required, the weight and form of which, however, will but slightly increase the cost of postage.

'5. What as to durability?

'Repeated experiments have proved that the indentations possess wonderful enduring power, even when the reproduction has been effected by the comparatively rigid plate used for their production. It is proposed, however, to use a more flexible plate for reproducing, which, with a perfectly smooth stone point--diamond or sapphire--will render the record capable of from fifty to one hundred repetitions, enough for all practical purposes.

'6. What as to duplication of a record and its permanence?

‘Many experiments have been made, with more or less success, in the effort to obtain electrotypes of a record, and the writer is informed that it has very recently been successfully accomplished. He can certainly see no great practical obstacle in the way. This, of course, permits of an indefinite multiplication of a record, and its preservation for all time.

‘7. What is the requisite force of wave impinging upon the diaphragm, and the proximity of the mouth to the diaphragm, to effect a record?

‘These depend in great measure upon the volume of sound desired in the reproduction. If the reproduction is to be made audible to an assembly, considerable force is requisite in the original utterance; if for the individual ear, only the ordinary conversational tone (even a whisper has been reproduced). In both cases the original utterances are delivered directly in the mouthpiece of the instrument. An audible reproduction may, however, be had by speaking at the instrument from a distance of from two to three feet in loud tone. The application of a flaring tube or funnel to collect the sound waves, and the construction of an especially delicate diaphragm and embossing point, &c., are the simple means which suggest themselves to effect this....

‘The foregoing presentment of the stage of development reached by the several essential features of the phonograph demonstrates the following _faits accomplis_:

‘1. The captivity of all manner of sound waves, hitherto designated as “fugitive,” and their retention.

‘2. Their reproduction with all their original characteristics, without the presence or consent of the original source, and after the lapse of any period of time.

‘3. The transmission of such captive sounds through the ordinary channels of commercial intercourse and trade in a material form, for purposes of communication.

‘4. Indefinite multiplication and preservation of such sounds, without regard to the existence or non-existence of the original source.

‘5. The captivation of sounds, with or without the knowledge or consent of the source of their origin...

‘The apparatus now being perfected in mechanical details will be the standard phonograph, and may be used for all purposes, except such as require special form of matrix, such as toys, clocks, &c., for an indefinite repetition of the same thing. The main utility of the phonograph being, however, for the purposes of letter-writing and other forms of dictation, the design is made with a view to its utility for that purpose.

‘The general principles of construction are, a flat plate or disk, with spiral groove on the face, worked by clockwork underneath the plate; the grooves are cut very closely together, so as to give a great total length to each length of surface--a close calculation gives as the capacity of each sheet of foil nearly 40,000 words. The sheets being but ten inches square, the cost is so trifling that but a hundred words might be put on a single sheet economically....

‘The practical application of this form of phonograph is very simple. A sheet of foil is placed in the phonograph, the clockwork set in motion, and the matter dictated into the mouthpiece without other effort than when dictating to a stenographer. It is then removed, placed in suitable form of envelope, and sent through the ordinary channels to the correspondent for whom it is designed. He, placing it upon his phonograph, starts his clockwork, and _listens_ to what his correspondent has to say.’

Since this paper by Mr. Edison appeared in June 1878, he has applied the phonograph to several other purposes, among which we may mention that of registering the force of sounds on railways, and especially on the metropolitan atmospheric railway in New York. The instrument which he has made for this purpose resembles that by Mr. Leo Scott, and bears the same name. It is described and represented in the ‘Daily Graphic’ of July 19, 1878, as well as the aerophone, the megaphone, and the microtasimeter, which is adapted for astronomical observations. We should exceed the limits laid down for this volume, if we were to give a more detailed account of these inventions.

M. Lambrigot, one of the officials on the telegraphic lines in France, and the author of various improvements in the Caselli telegraph, has shown me a phonographic system of his own invention in which it is reduced to its simplest form. He sent me the following description of his system.

‘The instrument consists of a wooden slab placed vertically on a stand and firmly fixed upon it. There is a round opening in the middle of the slab, covered by a tightly stretched sheet of parchment bearing a steel knife, which, like the tracing point of the

phonograph, is intended to trace the vibrations. A solid block rises from the stand to the middle of the slab, and supports a slide on which a runner can move in front of the slab. There is a strip of glass on this runner, of which one side is covered with stearine. When the runner is moved to and fro, the stearine comes in contact with the knife and takes the mould of its form, which is curved throughout.

‘A sound places the sheet of parchment in vibration, and imparts its movement to the knife, which traces various lines on the surface of the stearine.

‘The reproduction thus obtained on the strip of glass is subjected to the ordinary processes of metallisation. By galvanism a deposit of copper is obtained which reproduces the lines in an inverse way. In order to make the metallic plate speak, it is necessary to pass a point of ivory, wood, or horn lightly over the signs, and, by moving it more or less quickly, the different tones can be heard, just as they were spoken.

‘Since copper is relatively harder than lead, the copper plate on which the vibrations are traced will afford an unlimited number of reproductions. To obtain this result, a lead wire must be applied to the plate, and due pressure must be exerted on it. The wire is flattened and takes the impression of all the traces which then appear in relief. If the edge of a card is passed through this impressed tracing, the same sounds are produced as those which are obtained from the copper plate.’

M. Lambrigot suggests that the speaking plates might be useful in many ways: for example, they might make it easy to learn the correct pronunciation of foreign languages, since a sufficient number might be collected to make a sort of vocabulary which would give the accent of the words most in use in a given language.

By this simple process M. Lambrigot has been able to obtain a strong impression, within a copper groove, of the vibrations caused by the voice, and they are so distinctly engraved that whole sentences may be heard, if they are retraced by the sharpened point of a match. It is true that the reproduction is imperfect, and that those words are only to be distinguished which were previously known; but it is possible that better results will be obtained from improvements in the system, and at any rate the distinct impression of the vibrations of the voice on a hard metal is a really interesting discovery.

I have made one somewhat important observation in the working of the phonograph--namely, that if speech is registered on the instrument in a very hot room, and it is then carried to a colder room, the reproduction of speech is imperfect in proportion to the difference of temperature. This is probably owing to considerable modifications in the elasticity of the caoutchouc pad which is inserted between the tracing point and the vibrating disk: perhaps differences of expansion in the tinfoil have also some effect.

FABER’S AMERICAN SPEAKING MACHINE.

About two years ago the newspapers announced with some pomp that a speaking machine had reached Paris, which far surpassed Vaucanson’s duck, and which would attract general attention. Unfortunately the invention was not in the first instance brought forward with any scientific authority, and was soon relegated to take a place among the curiosities exhibited by conjurors. In a country so essentially critical and sceptical as France, there are always those who profess incredulity, and who will even resist evidence, and it was asserted that the machine only spoke because its exhibitor was an able ventriloquist. This is an old assertion which has lately been made with reference to the phonograph. Some scientific papers echoed the absurdity, and the speaking machine was so discredited that it is now unnoticed, although it is a most ingenious and interesting conception. When will our country be cured of the error of denying everything without due examination?

Since we ourselves only judge of things after having seriously considered them, we think it just to vindicate the truth as to Mr. Faber’s machine, and this can only be done by an exact description of it.

As I said in the last chapter, there is a great difference between the production and the reproduction of a sound, and a machine like the phonograph, adapted for the reproduction of sound, may differ essentially from a machine which really speaks. In fact, the reproduction even of articulate sounds may be very simple, as soon as we possess the means of stereotyping the vibrations of air necessary to transmit these sounds; but in order to produce them, and especially to emit the complex vibrations which constitute speech, it is necessary to set in motion a number of special organs, fulfilling more or less exactly the functions of the larynx, the mouth, the tongue, the lips, and even the nose. For this reason, a speaking machine is necessarily very complicated, and this is precisely the case with the machine we are now considering. Such a machine is not now made for the first time, and the Academy has lately been reminded of a speaking head which was in the possession of the philosopher Albertus Magnus in the thirteenth century, and which was destroyed by St. Thomas Aquinas as a diabolical invention.

Mr. Faber's speaking machine was exhibited two years ago at the Grand Hôtel, and may now be seen in the room adjoining M. Robert Houdin's theatre, the same room in which Mr. Giffard exhibited the telephone. It consists of three distinct parts: 1st, of a large bellows worked by a pedal, which produces the currents of air necessary for the production of sounds, and to some extent acts as the lungs; 2nd, a vocal instrument, consisting of a larynx accompanied by diaphragms of various forms to modify the sounds, of a mouth with caoutchouc lips and tongue, and of a tube with an outlet somewhat resembling the nasal cavities; 3rd, of a system of jointed levers and of pedals, terminating in keys like those of a piano.

The most interesting part of the machinery, of which we represent the principle fig. 73, is the vocal apparatus, which involved the severest study of physics in order to succeed in the production of articulate sounds. It consists, first, of a rather thick caoutchouc tube, within which there is a kind of whistle L, as in a clarionet. The whistle consists of a small caoutchouc cylinder with a longitudinal slit, and before this is placed a very thin ivory plate lined with caoutchouc. This plate is fixed at one end to the cylinder, and deviates slightly from it at its free end, so as to permit the current of air projected from the bellows S to penetrate between the two parts, and to cause the vibrations in the ivory plate necessary for the production of a sound. The extremity of the caoutchouc cylinder is closed on this side, and is fitted to an iron rod _t_ which comes out of the pipe, and is connected with a system of bars, corresponding to the keyboard of a piano, by which the force of sounds can be regulated. This force depends on the width of the opening between the tongue and the cylinder.

[Illustration: FIG. 73.]

The whistle, which plays the part of the larynx, is necessarily placed opposite the opening of the bellows, and a sort of tourniquet M is fastened to the opening itself, which is able to move on certain conditions, so that it may produce the rolling sound of _r_. This is done by fastening before the opening a diaphragm in which there is a somewhat wide and long slit, and this slit can be almost closed by a little bar of the same size M, revolving on a transverse axis which supports it by its centre. In its normal condition, this little bar is kept in a slanting position by cords attached to the keyboard, and the air ejected by the bellows readily traverses the slit in order to reach the larynx; but two dampers are fastened to the rods which transmit movement, with which the cords just mentioned are also connected. On lowering the notes of the key-board, the passage of air is contracted, and the little plate begins to oscillate and to press against a band of leather, producing by its vibration an action similar to that produced by the cricket. This little tourniquet only begins to act when the dampers are lowered by a pedal worked by the hand; and this is also the case with the iron rod _t_, which modifies the acuteness of the sounds passing through the larynx.[22]

Below the larynx tube, which is only five centimètres in length, there is another pipe G, also of caoutchouc, which terminates in a spherical cavity connected with the outer air by a caoutchouc tube I, slightly raised, and closed by a valve, of which the movements are regulated by a pedal worked by the keyboard. When the valve is open, the sounds emitted through the larynx are somewhat nasal.[23] The larynx communicates with the mouth through a square funnel-shaped pipe, to which six metallic diaphragms D are fastened; the diaphragms are placed in a vertical position behind each other, and have indentations on their lower end, which are intended to diminish more or less the orifice for the current of air, and to impede its passage with greater or less force. The diaphragms, which we represent separately fig. 74, are connected with the keyboard by jointed iron rods _t_, and, for the emission of most articulate sounds, several of the diaphragms are moved at the same moment and at different heights. We shall return to this subject.

[Illustration: FIG. 74.]

The mouth consists of a caoutchouc cavity O, somewhat resembling the human mouth, and forming a continuation to the channel we have just described. The tongue C, likewise modelled on the human tongue, is placed within the mouth, and connected with two jointed rods _t_, _t_, fastened to its two opposite ends, so as to enable the tongue to raise its tip, or touch the palate, in obedience to the notes of the keyboard. The lower caoutchouc lip A can also be more or less closed, according to the action of the keyboard on its special rod. Finally, a circular metallic piece E, following the shape of the mouth, is placed above the upper lip, with a small opening in it to admit of the pronunciation of the letter _f_.

The keyboard has fourteen notes, of different lengths, producing the following letters when lowered, _a_, _o_, _u_, _i_, _e_, _l_, _r_, _v_, _f_, _s_, _ch_, _b_, _d_, _g_. The longest corresponds to _g_, and the shortest to _a_. There are two pedals below the _g_ note and those of _b_ and _d_, corresponding with the opening of the tube which produces nasal sounds, and to the rod which regulates the opening of the larynx, and this makes it possible to obtain _p_, _t_, and _k_ from the notes _b_, _d_, _g_. The mechanical effects produced by lowering the different notes in succession are as follows:--

1. The _a_ note moves the first five diaphragms.

2. _o_ also moves these five diaphragms, but varies the pitch, and closes the mouth a little.

3. _u_ does the same, only further closing the mouth.

4. _t_ moves a single diaphragm, raises the tip of the tongue, and opens the mouth more widely.

5. _e_ moves six diaphragms, throws the tongue further back, and opens the mouth still more.

6. _l_ moves five diaphragms, sends the tongue against the palate, and further opens the mouth.

7. _r_ moves six diaphragms and the tourniquet, lowers the tongue, and somewhat closes the mouth.

8. _v_ moves five diaphragms, almost closes the mouth, and keeps the tongue down.

9. _f_ lowers the circular appendix of the upper lip, and almost entirely closes the mouth.

10. _s_ moves three diaphragms, half closes the mouth, and half raises the tongue.

11. _ch_ moves three diaphragms, keeps the mouth half closed, and further lowers the tongue.

12. _b_ moves five diaphragms, closes the mouth, and keeps the tongue completely down.

13. _d_ moves six diaphragms, keeps the mouth three parts closed, and raises the tongue a little.

14. _g_ moves five diaphragms, keeps the mouth three parts closed, and the tongue completely down.

_m_ is produced by lowering note _b_ and opening the valve of the pipe which gives nasal sounds.

_n_ is obtained by lowering note _d_ and opening the same valve.

_h_ is obtained from note _s_ by lowering the pedal which acts upon the larynx, and half closing it.

Since the other letters of the alphabet are compound sounds, they can be produced by combinations of the preceding letters.

Although the words pronounced by this machine are distinct, they are spoken in a uniform, drawling tone, which might, I should have thought, have excluded the idea of imposition. Some of them are indeed far from distinct, yet the results are not less remarkable; and when we consider the amount of study and experience which must have been applied to the combination of all these arrangements, it seems surprising that physicists have not given more attention to such an interesting machine.

As for the mechanical execution, it is impossible to admire too highly the simple and ingenious manner in which all the complicated movements of the different vocal organs have been connected with the keyboard, of which the mechanism has been so calculated as only to produce the precise action of the organ which is required for any given effect. For this purpose, the notes of the keyboard regularly increase in length, so as to produce at a single touch different mechanical effects on the rods which act upon the mechanism; and since most of the notes are required to react simultaneously on the whole mechanism, the rods which transmit the movement are fastened to a series of jointed levers which cross the notes of the keyboard at right angles. Pegs of different length are fastened to the notes at this junction, so as to produce the simultaneous action of the different organs of the machine.

The public will believe that the assertions of ventriloquism are unfounded when I add that I myself have made the machine speak.

APPENDIX.

The Perrodon System of Telephonic Alarum.--Captain Perrodon, of the French Artillery, has lately improved the system invented by MM. Dutertre and Gouault, by a self-acting call. For this purpose he has fastened a spring contact before the diaphragm, combined with the diaphragm and the electro-magnetic system so as to form a vibrator. The vibrations thus produced are strong enough to resound in an ordinary telephone, so as to make the call audible in spite of external noises.

The system has been arranged in different ways. In one arrangement, a small plate of tinfoil is glued to the outer surface of the diaphragm, and the end of the telephone coil wire is connected, below the inner surface of the mouthpiece, with a silver wire soldered to a spring plate, which constitutes the contact of the vibrator. This spring plate, slightly curved, is fixed below one of the

binding-screws of the telephone, and terminates at its free end in a regulating screw by which the interval between the contacts can be regulated, and the instrument can be arranged as a telephonic organ. To do this, the screw can be withdrawn, and inserted in a nut which establishes direct connection between the line and the telephone coil. It is easy to adapt an ordinary telephone to this system.

In another arrangement M. Courtot's mirror telephone has been employed, and a sort of spring pedal is inserted in the wood of the mouthpiece, which terminates in a bent silver wire, supporting an index adapted to make a contact with a square plate soldered to the diaphragm. The battery is placed in connection with the spring of the pedal, and one end of the telephone coil-wire communicates as before with the diaphragm. When a call is to be made, the pedal must be pressed, and the battery immediately communicates with the silver wire which, with the diaphragm, constitutes the vibrator, and an electric vibration is sent through the circuit, and produces the call. For receiving, the pedal is allowed to revert to its normal position, and the index of the pedal, touching the contact in connection with the diaphragm, establishes direct communication between the two telephones, while breaking the contact of the silver wire with the diaphragm, so that the battery cannot act.

It appears that experiments made at the musketry school at Orleans for a distance of 370 miles have been very successful.

M. Varey's Microphone Speaker.--M. Varey has recently arranged a successful microphonic speaker, in which the principle of the microphone represented in fig. 39 is maintained. The system of three vertical carbons is arranged inside a sort of snuff-box, of which the lid is made of a thin plate of mica, horn, or ebonite. The snuff-box is provided with two hinged arms, so that it may be placed in the most convenient position for speaking, and at the same time the sensitiveness of the instrument can be regulated. A small battery, consisting of two Gaiffe cells of chloride of silver, is placed in the pedestal on which the instrument stands, and sets the microphone at work without further trouble. In this way the speaker can be used like an ordinary telephone, and is not affected by vibrations of air. Only vibrations of sound react upon it.

Microphonic Speaker by Fitch.--Mr. Pope states that this speaker has produced excellent results in America. It is merely Edison's carbon telephone reduced to its simplest form. It consists of a small cylindrical box, which has a mouthpiece like the one represented fig. 28. The box contains two carbon disks of the same diameter as itself, and is lined with a kind of felt. Metal wires, inlaid in a groove scooped on the circumference of the carbons, place them in communication with the circuit and battery, and transmission takes place by means of the vibrations of the upper carbon, which is directly influenced by the voice without the intervention of any diaphragm. These vibrations, which can be freely developed in consequence of the elasticity of the felt pad which supports the lower carbon, produce on the surface of contact of the two carbons the modifications of intensity of current necessary for the reproduction of speech, in the same way as other microphones.

An induction coil is necessarily employed for a long circuit, and the effects of induction in the adjacent wires are modified by two rheostats introduced into the circuit at its two extremities.

Further remarks on the theory of the Telephone.--Following the example of a certain sceptic in the Académie des Sciences, Colonel Navez continues to maintain the theory first formed as to the mode in which the telephone acts, in spite of the clearest proofs of its insufficiency; but most scientific men who consider the question have come round to our opinion, and admit the concurrence of several causes in the reproduction of speech by this remarkable instrument. Mr. Fleeming Jenkin writes to this effect in the new edition of a treatise on Electricity and Magnetism.

He observes that a singular fact has been discovered by several persons, who have ascertained that not merely non-magnetic and non-conducting bodies can be substituted for the diaphragms of receiving telephones, but that they will act without a diaphragm at all. In this case it is evident that we have to do with the sounds discovered by Page, and that they are produced by the magnet itself, in which each molecular movement constitutes the source of the sound produced. This sound becomes articulate as soon as its increase and decrease can follow the increasing or decreasing action of the voice which produces it at the sending station. It is certain that when the transmitted currents are due to the action of the Bell diaphragm, the sounds due to the Page effects ought to correspond with those which would be given by iron diaphragms adapted to the receiving instruments; so that, when a telephone has an iron diaphragm, there are in fact two voices, that of the diaphragm, which is strong, and that of the magnet, which is weak. When a disk of wood is substituted for one of iron, it acts as a sounding board for the Page effect, and when the disk is of metal, induction is developed by the magnetic modifications, and tends to produce vibration, thus developing a third source of sound, which may be called the Ampère effect. Finally, a fourth source of sound may result from the induced effects produced in the wire itself in consequence of changes in the intensity of current. These sounds, first observed by M. de la Rive, have since been studied

by Mr. Fergusson of Edinburgh (vide ‘Telegraphic Journal’ of November 1, 1878).

Mr. Fleeming Jenkin’s opinion only differs from mine in his ascribing the energy of sound acquired by a telephone with an iron diaphragm to the preponderance of sounds in the latter, whereas I consider it to be chiefly due to the increase of energy in the whole magnetic system produced by the reaction of the two magnetic parts on each other. If the two effects could be taken singly, it is probable that the sounds produced by each of them separately would be similar, since in magnetic effects the reaction and action are equal. But as they are combined, it becomes difficult to assign to each the share which belongs to it in the general effect observed. Besides, it is quite possible that the sounds of the diaphragm may appear to be stronger and more distinct because it is nearer to the ear than the magnet, and because the effects of magnetisation and demagnetisation are then more easily produced in consequence of the mass of the magnetic body being smaller.

Mr. Fleeming Jenkin goes on to say that the question of the displacement of surface in the diaphragm and magnet is very complex, but that he thinks it impossible to deny the existence of such displacement, since the air which acts as the vehicle of sound between the ear and the source of sound is placed in vibration; yet this displacement maybe effected quite otherwise than by flexion. Suppose that the magnetic molecules of these bodies are drawn together by magnetisation, which tends to diminish the intermolecular space which separates them, the points of surface of the substance corresponding to these intervals will be elevated in a manner equivalent to a displacement of surface, and the effect of this will be the same as a flexion movement. At the moment of demagnetisation a depression instead of an elevation will take place, and the vibratory movements will thus be produced without any electro-magnetic attraction, and it is precisely these vibrations which Mr. Fleeming Jenkin terms molecular vibrations. He evidently does not mean that such attractions cannot take place: they may react, together with the molecular vibrations, when the electric force is capable of producing them. He adds that the reproduction of sounds by a condenser, by simple coils, and by a carbon microphone, has convinced him that the action just analysed requires generalisation.

We have recently seen an article by Mr. Hughes in the ‘Telegraphic Journal,’ Nov. 15, 1878, in which, to our surprise, he not only opposes all the theories he has hitherto held, but cites experiments which are quite inconclusive, since they were performed under conditions in which electro-magnetic effects must necessarily be displayed. He made use of voltaic currents produced by a battery of three Daniell cells. In order to estimate the transverse effects resulting in such a case from attraction, the experiments he mentions are wholly unnecessary: they may be felt with the hand. On the other hand, he has evidently forgotten that the currents employed in a Bell telephone have no influence on a very sensitive galvanometer.

M. Pollard’s Microphone.--This microphone, which has been arranged in several ways, essentially consists of a carbon rod kept in a horizontal position by a wire, and resting on two other vertical carbons. The upright of the arm which holds the wire can revolve together with this arm, and is thus able to regulate the pressure of the horizontal carbon on the two vertical carbons. It appears that this instrument is extremely sensitive, and that the regulation effected on the two contacts is better than when it is effected on one only. It is fair to add that M. Voisin previously sent me the sketch of a somewhat similar arrangement.

M. Dutertre has also made use of such an arrangement in what he calls the Dolmen microphone. Three pieces of coke in the form of a dolmen, that is, two uprights, supporting a third and horizontal carbon, are placed in circuit. M. Gouault has informed me that speech was well transmitted by this instrument, and it is, like that of Mr. Blyth, which succeeded it, of wonderful simplicity.

This microphone, as well as one composed of two pieces of lead-pencil placed in a watch-case, and connected by a piece of money, were exhibited to the Industrial Society at Rouen, February 1, 1878, of which an account was published in the Bulletin of that society.

M. Ader’s Electrophone.--M. Ader has recently constructed a remarkable telephonic instrument, which reproduces speech and song in a quite exceptional and simple way. It consists of a drum 15 centimètres in diameter, covered with parchment at one end only. Six small tin armatures, one centimètre in length and two millimètres in width, are fixed in the centre of the parchment in a circle six centimètres in diameter. Six microscopic electro-magnets, whose distance from the armatures can be regulated by a screw, are placed opposite the armatures within a wooden circle. The magnets are horseshoe, with branches 12 millimètres long and 4 millimètres in diameter, including the coils, and the magnetic core is 1½ millimètre thick. They are all in connection, and act simultaneously under the sole influence of the battery current. The sender is the same as that of M. Ader described before. With this instrument speech may be heard at a distance of six or seven yards, and songs are much more distinctly heard than in the singing condenser. Owing to the simplicity of the arrangement, the instrument is not costly.

The extraordinary effects of this telephone are due to the small size of the electro-magnets, which, as we believe, produce much more rapid magnetic effects than those of larger size. M. Ader has also made a small ordinary telephone based on this principle, of which the sounds are much stronger than in others.

Modification of Bell Telephone.--Mr. Gower has recently made a new system of telephone without a battery, which not only reproduces speech loudly enough to be heard at the distance of eight or nine yards from the instrument, but will also transmit it when the speaker is at a moderate distance from the sending instrument. In this latter case, indeed, the receiving telephone must be brought close to the ear. Although this double problem had already been solved by the use of telephones with microphonic senders, the results furnished by the instruments in question are still more curious, since they are obtained without batteries, and are even more distinct.

In this new system, which is only an improvement on Bell's square model, the horseshoe magnet is of a peculiar form, which renders it more powerful. It is formed of a kind of half-circle of magnetised steel, with its two ends turned back, so as to form a diameter of the circle, only this diameter is divided in the centre: so that the two poles of the magnet are placed one before the other, as in Faraday's electro-magnet. The poles are tipped with iron, terminating in front in two thin iron plates, on which are placed the electro-magnetic coils, which are oblong, and constitute the magnetic core. The diaphragm, thicker than the ordinary diaphragms, is of tin, and is fixed firmly to the edges of the circular box which encloses the whole, and which forms a kind of sounding-box. The box is made of copper, and the diaphragm is so firmly fastened to it as to become homogeneous with it, and to give out a sound when the box is touched, which is not the case in ordinary telephones. This is one of the conditions which make the instrument a better conductor of sound. The magnet is also much more powerful. It is magnetised by a current from a powerful Gramme machine, which acts upon it for almost twenty minutes. The instrument has, strictly speaking, no mouthpiece: the lid of the box which supports the diaphragm, and is separated from it by a space of two millimètres, has merely a hole bored in it above the centre of the diaphragm, and into this hole either a tin trumpet, 50 centimètres in length, is screwed, when the instrument is required to reproduce or transmit speech to a distance, or an acoustic tube when it is to be used like an ordinary telephone. The remarkable part of the system is that the instrument can itself give a very loud call by only breathing into it instead of speaking.

For this purpose a small oblong opening is made in the diaphragm at a half diameter from its centre, and behind this the reed of an harmonium is applied to a square copper plate fixed on the diaphragm itself. On using the bellows the expelled air passes through this little hole, and, on reaching the reed, sets it in vibration, and produces a sound of which the acuteness depends on the conditions of the vibrating plate. This addition to the diaphragm in no way alters its properties in the reproduction of speech, so that, after using the bellows, conversation may begin, and the receiving telephone repeats what is said after emitting a sound somewhat resembling the note of a bugle. The instrument is then provided with the speaking tube of which we have spoken.

Nothing can be more remarkable than this power of listening to conversation while seated in an armchair six or seven yards from the instrument, nor is it necessary to move in order to reply. The correspondent, indeed, must be close to the acoustic tube in order to speak and listen, and he must speak rather loud in order to be heard at any distance from the other station. But the listener receives the sounds so amplified that it might be supposed that a giant was speaking, and conversation held in a low tone may even be distinguished. These results are really extraordinary, and even to those familiar with such effects this incessant progress is surprising.

These results may be ascribed to the following causes:--

1. First, that the conditions of the magnet are better than those of ordinary instruments.

2. That the diaphragm is also thicker, larger, and better stretched.

3. That the box is of metal, and calculated to act as a sounding-box.

4. The speaking trumpet magnifies the sounds.

5. The acoustic tubes concentrate the sound waves on the centre of the diaphragm.

Note on some fresh Experiments with Telephones without any Diaphragm.

In a paper published March 4, 1878, I made some suggestions on the theory of the sounds produced in the telephone, and on the contradictory assertions of physicists as to the transmission of speech by ordinary telephones when devoid of diaphragm. These remarks induced M. Ader to undertake some experiments which not only demonstrate the truth of my opinion, but bring to light

some fresh facts which may be of great importance to acoustic science.

M. Ader has in fact not only succeeded in making a telephone without a diaphragm speak, but he has made it speak more loudly and with less alteration of the voice than we find to be the case with a small model of the ordinary telephone. No one, therefore, can now maintain that the sounds produced by the magnetic cores are so faint that they cannot be taken into account among the effects produced, and that it is at any rate impossible for them to reproduce articulate sounds.

To obtain this result, M. Ader reduced the size of the magnetic core to that of a simple iron wire, one millimètre in diameter, and he fastened it by one of its ends to a small wooden board. Under these conditions, it was enough to fasten a small helix of fine wire on this iron wire, and to apply the board to the ear in order to hear speech distinctly, with the aid of a microphonic speaker actuated by a voltaic current. But the range of sound was considerably increased if a mass of metal was applied to the free end of the iron wire: in this case it was possible to hear when the wooden board was removed to a distance of ten or fifteen centimètres from the ear.

If the wire is in contact with masses of metal at each end, the effect is further increased; but the two masses must not be in metallic communication with each other, and must be to some extent insulated by a more or less elastic medium. If the metallic masses are soldered to the wire, the effects are still greater.

M. Ader was also able to reproduce speech by using a simple coil without a magnetic core, but in this case the spirals must be open, and not pressed together. If they are steeped in gum, no sound is heard, but speech will become instantly audible if a wire or a magnetised needle is inserted in the coil, or even if a second metallic helix is placed in the circuit: always provided that one of the ends of these magnetic organs rests upon, or is fastened to, the board on which the coil is fixed.

M. Ader has likewise obtained a very distinct reproduction of speech at a distance of two or three yards from the instrument by inserting between the two stretched membranes of two tambourines a bent wire which acts as a spring and passes through an electro-magnetic coil. Under these conditions, magnetisation of the wire in a greater or less degree affects its elasticity and causes vibrations which are magnified by the membranes, and transmitted sounds are reproduced with intensity. Unfortunately articulate speech is less distinct with this system than with the one I described before.

M. Ader has often had occasion to make one curious remark, namely, that the _timbre_ of the voice and its high or low key varies with the degree of tension given to the wire; but if the fundamental note of the wire is deadened by pressing it between the fingers, the sounds reproduced then become dull and monotonous. They are also somewhat fainter.

Signor Carlo Resio has also observed that in a telephone sender the variations of intensity in the current correspond with the vibrations caused by speech, and these are reproduced by corresponding variations in a liquid column, which may thus act as a telephone receiver, and consequently may reproduce speech without any electro-magnetic organ, as in a microphone speaker. Under these conditions, however, a layer of water is inserted between the platinum electrodes and the surrounding air, and consequently this liquid layer must be put in vibration under the influence of varying intensities of current.

Mr. Edison has also now made a practical application of the chemical telephone we have mentioned before. The trials made with it have been very satisfactory, showing that sounds transmitted in this way can be heard in a large room.

PRINTED BY SPOTTISWOODE AND CO., NEW-STREET SQUARE LONDON

FOOTNOTES

[1] Mr. Gray, in an article inserted in the _Telegrapher_ of October 7, 1876, enters into full details of this mode of transmitting sounds by the tissues of the human body, and he gives the following as the conditions in which it must be placed to obtain a favourable result: 1. The electricity must be of a high tension, in order to have an effect perceptible to the ear.

2. The substance employed to touch the metallic plate must be soft, flexible, and a good conductor, up to the point of contact: it must then interpose a slight resistance, neither too great nor too small.

3. The disk and the hand, or any other tissue, must not only be in contact, but the contact must result from rubbing or gliding over the surface.

4. The parts in contact must be dry, so as to maintain the required degree of resistance.

[2] He cites the following names in his account of electric telephony:--Page, Marrian, Beatson, Gassiot, De la Rive, Matteucci, Guillemin, Wertheim, Wartmann, Janniar, Joule, Laborde, Legat, Reiss, Poggendorf, Du Moncel, Delezenne, Gore, &c. Vide Mr. Bell's paper, in the _Journal of the Society of Telegraphic Engineers_ in London, vol. vi. pp. 390, 391.

[3] This statement is disputed by Mr. Elisha Gray, owing, as we shall see, to a misunderstanding as to the word _undulatory_ current.

[4] _Elisha Gray._ Eng. Pat. Spec. No. 2646, Aug. 1874.

[5] This property has long been known, but not applied. In 1856, in the second edition of my _Exposé des applications d'Electricité_, I pointed them out in speaking of the contact-breakers. I also spoke of them in a paper on electro-magnets (published in the _Annales télégraphiques_, 1865), and in several articles laid before the _Académie des Sciences_ in 1872 and 1875 on the conductivity of filings and conducting powders. M. Clérac, in 1865, also used them to obtain variable resistances.

[6] In 1865 I was able to verify this observation when tightening the spirals of an electro-magnet on a naked wire. The greater the number of spirals under pressure, the more definite were the differences of resistance in the magnetising helix.

[7] M. Hellesen communicated the plan of his instrument to me on May 3, 1878, and his experiments were made in Copenhagen three weeks earlier.

[8] M. M. J. Page had already noticed that if a telephone is placed in the circuit of the primary helix of an induction coil, while the secondary helix of this instrument is placed in the circuit of one of M. Lippmann's capillary electrometers, a movement of the mercurial column of the electrometer takes place at each word, and this movement is effected towards the capillary end of the tube, in whatever direction the current is sent by the telephone. This is because the mercury always tends to move more rapidly at its capillary end than at the other extremity.

[9] Mr. Edison, in a letter written November 25, 1877, writes that he has made two telephones which act with copper diaphragms, based on Arago's effects of magnetism by rotation. He ascertained that a copper diaphragm might replace the iron plate, if its thickness did not exceed 1/32 of an inch. The effect produced is slight when the copper diaphragm is placed between two corresponding instruments; but when the sender only is furnished with the copper diaphragm, and the receiver is arranged as usual, communication becomes easy.

Mr. Preece repeated these experiments, but he only obtained very slight and indistinct effects: he consequently believes that they are of no practical use, although very interesting in theory.

[10] Mr. Bell had previously made a like experiment, which suggested to him that molecular vibrations had as much to do with the action of the telephone as mechanical vibrations.

[11] M. Bosscha, who has published in the _Archives néerlandaises_ an interesting paper on the intensity of electric currents in the telephone, says that the minimum intensity of currents necessary to produce a sound in a telephone by the vibration of its diaphragm may be less than 100/1000 of a Daniell element, and the displacement of the centre of the diaphragm would then be invisible. He was unable to measure exactly the range of movements produced in the diaphragm by the influence of the voice, but he believes it to be less than the thousandth part of a millimètre; and from this it follows that, for a sound of 880 vibrations, the intensity of the induced currents developed would be 0·0000792 of the unit of electro-magnetic intensity.

[12] Mr. Warwick describes his experiments as follows: 'The magnets employed were nearly of the usual size, 1½ inch in diameter, and nearly eight times as long. At first I employed iron disks, but I found them to be unnecessary. When I had discarded them, I tried several substances: first a thin disk of iron, which answered perfectly both for sender and receiver. A disk of sheet iron, about ■ of an inch in thickness, did not act so well, but all that was said was quite understood. In making experiments with the disks, I simply placed them above the instrument, without fixing them in any way: the wooden cover and the conical cavity were also laid aside, because the transmission and reception could be effected as well without them. This part of the instrument seems to be superfluous, since, when the disk is simply placed level to the ear, the sound seems to be increased by being brought nearer. Although iron acts better than anything, it appears that iron disks are not absolutely necessary, and that diamagnetic substances also act perfectly. I wished that my assistant, who was at some distance, and could not hear any direct sound, should continue his calculations. I took away the iron disk and placed across the instrument a wide iron bar, an inch thick. On applying my ear to it, I could hear every sound distinctly, but somewhat more faintly. A piece of copper, three inches square, was substituted for it:

although the sound was still distinct, it was fainter than before. Thick pieces of lead, zinc, and steel were alternately tried. The steel acted in almost the same way as the iron, and, as in the other cases, each word was heard faintly but distinctly. Some of these metals are diamagnetic, and yet the action took place. Some non-metallic substances were next tried; first a piece of window-glass, which acted very well. The action was faint with a piece of a wooden match-box; but on using pieces of gradually increasing thickness the sound was sensibly increased, and with a piece of solid wood, 1½ inch in thickness, the sound was perfectly distinct. I next replaced it by an empty wooden box, which acted very well. A piece of cork, ½ inch thick, acted, but somewhat faintly. A block of razor-stone, 2 inches thick, was placed upon the instrument; and, on applying the ear to it, it was quite easy to follow the speaker. I then tried to hear without the insertion of any substance, and, on applying my ear quite close to the coil and magnet, I heard a faint sound, and on listening attentively I understood all that was said. In all these experiments the sounds were perceived, but the sounds transmitted or attempted did not act precisely alike. The sound of a tuning-fork, placed on the iron disk itself or on the case of the instrument, was clearly heard: thin iron disks were more effective for articulate speech. With other substances, stone, solid wood, glass, zinc, &c., the sound of the tuning-fork was heard, whether it rested upon them, or the vibrating fork was held above them. These substances were not adapted for transmitting the sound of the voice. These were all laid aside, and the sounding instrument was held directly above the pole of the magnet: the sound was clearly heard, although there was nothing but air between the end of the magnet and the tuning-fork. The sound was perhaps less intense when the tuning-fork was held directly above the pole, than when it was at the end of the magnet. I next tried if my voice could be heard with this arrangement. The result was rather doubtful, but I think that some action must have taken place, for the tuning-fork was heard when it was simply vibrated near the pole. The effect of the voice can only have differed in the degree of intensity: it was too faint to be heard at the other extremity. I repeated these effects; I assured myself of them, and I succeeded in transmitting sounds distinctly on the pole without a disk, and, on the other hand, by applying my ear to the instrument, I was able to hear distinctly all that was said, although there was no disk.’

[13] These are his own words: ‘The articulation produced from the instrument was remarkably clear, but its great defect consisted in the fact that it could not be used as a sending instrument, and thus two telephones were required at each station, one for transmitting and one for receiving spoken messages.’

[14] These carbons are made by heating, in a temperature gradually raised to white heat, fragments of deal of a close fibre, which is enclosed in an iron tube or box hermetically sealed.

[15] Mr. Willoughby Smith varied this experiment by placing a packet of silk threads coated with copper on the disconnected ends of the circuit, which were arranged at right angles with each other. Under these conditions the instrument became so sensitive, that the current of air produced by a lamp placed above the system, caused a decided crackling noise in the telephone.

[16] Mr. Hughes observes on this subject that carbon is a valuable material for such purposes, since it does not oxidise, and its effects are greater when combined with mercury. He takes the prepared charcoal used by artists, brings it to a white heat, and suddenly plunges it in a bath of mercury, of which the globules instantly penetrate the pores of charcoal, and may be said to metallise it. He also tried charcoal coated with a deposit of platinum, or impregnated with chloride of platinum, but this was not more successful than the former method. If the charcoal of fir-wood is brought to a white heat in an iron tube, containing tin and zinc, or any other metal which readily evaporates, it is metallised, and is adapted for use if the metal is subdivided in the pores of charcoal and not combined with it. When iron is introduced into carbon in this way it is one of the most effective metals. The charcoal of fir-wood, in itself a bad conductor, may thus acquire great conducting power.

[17] Mr. Hughes remarks that the vibrations which affect the microphone, even in speaking at a distance from the instrument, do not proceed from the direct action of the sound waves on the contacts of the microphone, but from the molecular vibrations produced by it on the board which serves to support the instrument; he shows, in fact, that the intensity of sounds produced by the microphone is in proportion to the size of the surface of this board, and when the sending microphone is enclosed in a cylindrical case, its sensitiveness is not much diminished if the surface of the box enclosing the whole is sufficiently large. From this point of view he has sought to increase the sensitiveness of his instruments by fixing the frame on which the moveable parts of the sender and receiver revolve on a spring plate.

[18] Helmholtz’s resonator is based upon the principle that a volume of air contained in an open vase emits a certain note when placed in vibration, and that the height of the note depends on the size of the vase and of its opening. Helmholtz makes use of a globe with a large opening on one side and a small one on the other, and the small one is applied to the ear. If a series of musical notes take place in the air, the one which is in harmony with the fundamental note of the globe is intensified, and can be

distinguished from the rest. The same effect takes place when, on singing to a piano accompaniment, some strings are heard to vibrate more strongly than others, namely, those which vibrate in unison with the sounds emitted. The resonators are made in various ways; those most generally used are cases of different lengths which also serve as sounding-boxes.

[19] I give the text of M. Cros' sealed paper, opened by his request, at the Académie des Sciences, December 3, 1877:--'Speaking generally, my process consists in obtaining traces of the movement to and fro of a vibrating membrane, and in using this tracing to reproduce the same movements, with their intrinsic relations of duration and intensity, either on the same membrane or on one adapted to give out the sounds which result from this series of movements.

'It is therefore necessary that an extremely delicate tracing, such as may be obtained by passing a needle over a surface blackened by fire, should be transformed into a tracing, capable of sufficient resistance to guide an index which will transmit its movements to the membrane of sound.

'A light index is fastened to the centre of a vibrating membrane; it terminates in a point (a metallic wire or tip of a feather) which rests on a surface which has been blackened by fire. This surface forms part of a disk, to which the double action of rotation and rectilinear progression has been given. If the membrane is at rest, the point will trace a simple spiral; if the membrane vibrates, there will be undulations in the spiral, and these undulations will represent the precise movements of the membrane in their duration and intensity.

'By a well-known photographic process a transparent tracing of the undulations of the spiral can be represented by a line of similar dimensions on some resisting substance, tempered steel for example.

'When this is done, this resisting surface is placed in a turning machine which causes it to revolve and advance with a velocity and motion similar to those by which the registering surface was actuated. A metallic point if the tracing is concave, or a grooved index if it is in relief, is kept upon the tracing by a spring, and the index which supports this point is connected with the centre of the membrane which produces the sounds. Under these conditions, the membrane will be actuated not by the vibrating air, but by the tracing which guides the index, and the impulses will be precisely similar in duration and intensity to those to which the registering membrane was subjected.

'The spiral tracing represents equal successions of time by increasing or decreasing lengths. There is no inconvenience in this, since the turns of the spiral are very close together, if only the circumference of the turning circle is used; but then the central surface is lost.

'In all cases the tracing of the helix on a cylinder is much more satisfactory, and I am now trying to make this idea practicable.'

[20] Never make a contact between the stylus and the cylinder until the latter is covered with the tinfoil. Do not begin to turn the cylinder until assured that everything is in its place. Take care, when the stylus returns to the point of departure, to bring the mouthpiece forward. Always leave a margin of from five to ten millimètres on the left and at the beginning of the sheet of tinfoil; for if the stylus describes the curve on the extreme edge of the cylinder, it may tear the sheet or come out of the groove. Be careful not to detach the spring of the caoutchouc pad.

To fix the tinfoil, apply varnish to the end with a paint-brush; take this end between the finger and thumb of the left hand, with the sticky part towards the cylinder; raise it with the right hand and apply it quite smoothly to the cylinder; bring round the sticky end, and join them firmly.

To adjust the stylus and place it in the centre of the groove, bring the cylinder to the right, so as to place the stylus opposite the left extremity of the tinfoil; bring forward the cylinder gently and by degrees, until the stylus touches the tinfoil with force enough to imprint a mark. Observe if this mark is quite in the centre of the groove (in order to do this, make a mark with the nail across the cylinder), and if it is not, adjust the stylus to the right or left by means of the little screw placed above the mouthpiece. The depth of the impression made by the stylus should be ■ millimètre, just enough for it to leave a slight tracing, whatever the range of vibrations may be.

To reproduce the words, the winch must be turned with the same velocity as when they were inscribed. The average velocity should be about eighty turns a minute.

In speaking, the lips must touch the mouthpiece, and deep guttural sounds are better heard than those which are shrill. In reproducing, the tightening screw must be loosened and brought in front of the mouthpiece, the cylinder must be brought back to its

point of departure, the contact between the stylus and the foil must be renewed, and the cylinder must again be turned in the same direction as when the sentence was spoken.

To increase the volume of reproduced sound, a tube of cardboard, wood, or horn may be applied to the mouthpiece; it must be of a conical form, and its lower end should be rather larger than the opening of the mouthpiece.

The stylus consists of a No. 9 needle, somewhat flattened on its two sides by friction on an oiled stone. The caoutchouc pad which connects the plate with the disk serves to weaken the vibrations of the plate. If this pad should come off, heat the head of a small nail, apply it to the wax which fastens the pad to the plate or to the spring, so as to soften it; then press the caoutchouc lightly, until it adheres to the place from which it was detached. The pads must be renewed from time to time, as they lose their elasticity. Care must be taken in replacing them not to injure the vibrating plate, either by too strong a pressure or by grazing it with the instrument employed to fix the pad.

The first experiments should be with single words or very short sentences, which can be extended as the ear becomes accustomed to the instrument's peculiar tone.

The tone is varied by accelerating or slackening the rotatory movement of the cylinder. The cries of animals may be imitated. Instrumental music may be reproduced by placing a cardboard tube before the mouthpiece. The airs should be played in rapid time, since, when there is no system of clockwork, they will be more perfectly reproduced than those which are played slowly.

[21] We confess that we find it difficult to believe in this property of the phonograph, from which we have only heard the harsh and unpleasant voice of Punch.

[22] The action of this pedal is effected by two little rockers, so connected that the upper damper is lowered a little before the lower damper is raised--a condition necessary to produce the quivering motion of the plate which furnishes the rolling _r_.

[23] The arrangement of this part of the instrument is remarkable in this particular, that in the case of certain letters the air is ejected with more or less force through the pipe I, while in the case of other letters the air is drawn into the same tube. Since I was unable to see the internal arrangement of these cavities, I can only give an imperfect account of the mechanism at work.

Transcriber's Notes

Punctuation, hyphenation, and spelling were made consistent when a predominant preference was found in the original book; otherwise they were not changed.

Simple typographical errors were corrected; unbalanced quotation marks were remedied when the change was obvious, and otherwise left unbalanced.

Illustrations in this eBook have been positioned between paragraphs and outside quotations.

Footnotes, originally at the bottoms of the pages that referenced them, have been collected, sequentially renumbered, and placed near the end of the book.

The Table of Contents is not well-coordinated with the actual text. The Transcriber has not added missing entries, but has attempted to correct page number discrepancies.

Several diagrams use labels with prime marks, but the accompanying explanations do not always include the prime marks.

FIRST EDITION 1899 SECOND EDITION 1902 THIRD EDITION 1906 FOURTH EDITION 1920

PREFACE TO THE FOURTH EDITION

A science is said to be known by its literature and, if that be true, Osteopathy is backward for there are few available books on the subject for the student and investigator although there is a vast amount of unclassified journalistic matter. A pretentious start was made and, for a time, it appeared that we should have texts on all subjects for the teaching of Osteopathy but, for reasons not necessary to give here, these books did not live although their value and need was never questioned.

The third edition of the Practice of Osteopathy was exhausted very soon after publication and there have been insistent calls for a fourth which is now presented with the hope that it will find as friendly a reception as was accorded the previous editions. Close attention to current literature has been given and reports from experienced practitioners in the field has been sought and this material made use of wherever possible. Besides this, certain sections have been written by specialists in their several lines whose signed articles we confidently present. The subject of osteopathic practice has been handled to avoid undue optimism in the light of experience but, also, not to lose sight of the fact that osteopathy won its way by performing the so-called impossible in a multitude of cases. Therefore, it has been thought best not to draw a hard and fast line on our limitations.

The border line between osteopathy and surgery has been demonstrated as well as can be done on paper without the actual patient in hand. Medical literature has been called upon to give its store of knowledge wherever our needs have appeared and all osteopathic prints have, also, given from their accumulated wisdom and experience.

The authors acknowledge, with thanks, this information from the many writers for osteopathic journals who have created a great fund of knowledge on osteopathic subjects and particularly those who have contributed special sections.

CARL PHILIP MCCONNELL. CHARLES CLAYTON TEALL.

1920.

“Osteopathy is not so much a question of books as it is of intelligence. A successful osteopath is in all cases, or should be, a person of individuality with a mechanical eye behind all motions or efforts to readjust any part of the body to its original normality, because unguided force is dangerous, often doing harm and failing to give relief that should be the reward of well directed skill.”—A. T. STILL.

LIST OF CONTRIBUTORS

RAYMOND W. BAILEY, D. O.

Former member of the faculty, Philadelphia College of Osteopathy.

(_Defective Children_)

EDGAR S. COMSTOCK, D. O.

Professor of Principles of Osteopathy, and of Respiratory and Infectious Diseases, Chicago College of Osteopathy.

(_Infectious Diseases_)

J. DEASON, M.S., Ph. G., D. O.

Professor of Rhinology, Laryngology and Otology, Chicago College of Osteopathy.

(_Ear, Nose and Throat_)

L. VAN HORN GERDINE, A. M., M. D., D. O.

Neurologist, Still-Hildreth Sanatorium.

TABLE OF CONTENTS

PART I.

INTRODUCTION 17

OSTEOPATHIC ETIOLOGY AND PATHOLOGY 24

Osteopathic lesion; Etiological factors; Osseous lesion; Muscular lesion; Ligamentous lesion; Visceral lesion; Composite lesion; Pathology; Spinal lesions; Proof.

OSTEOPATHIC DIAGNOSIS AND PROGNOSIS 38

The Spine; Examination; Vertebræ; Position in examination; Neck, Head and Face, Atlas, Axis, Skull, Third Cervical, Muscles of the Neck, Temporo-Maxillary Articulation, Scalp, Ribs, Clavicle, Sternum, Dorso-Lumbar, Thorax, Abdomen, Gall Bladder, Spleen, Stomach, Intestines, Kidneys, Lumbar, Pelvis, Coccyx, Arms, Legs.

OSTEOPATHIC PROGNOSIS 56

OSTEOPATHIC TECHNIQUE 60

Sense of touch, Definite principles, General treatment, Position, Neck, Head, Ribs, Dorsal, Lumbar, Abdomen, Pelvis, Legs, Arms, How often to treat, Length of treatment, Over-treatment, Misapplied treatment.

OSTEOPATHIC CENTERS, STIMULATION, INHIBITION, READJUSTMENT, VASOMOTOR AND SENSORY NERVES 88

SPINAL CURVATURE 96

POTT'S DISEASE 102

SPRAINS 104

FLAT FOOT 112

FRACTURES 115

POSTURAL DEFECTS 120

Round Shoulders, Painful Shoulders, Pendulous Abdomen, Postural Curvature of the Spinal Column.

PROLAPSED ORGANS 133

Prolapsed and Dilated Stomach, Prolapsed Kidney, Liver Prolapse, Prolapsed Intestines, Prolapsed Uterus, Ovarian Displacements.

SKIN DISEASES 147

Eczema, Herpes Simplex, Herpes Zoster, Urticaria, Acne.

ANIMAL PARASITES 151

Tape Worm, Round Worm, Pin Worm, Hook Worm, Trichiniasis, Filaria.

HEMORRHAGES 160

Epistaxis, Hemoptysis, Hematemesis, Intestinal Hemorrhage, Hematuria, Uterine Hemorrhage.

HICCOUGHS 165

VARICOSE VEINS 166

PHLEBITIS 168

THE RECTUM 169

Local Treatment, Proctitis, Hemorrhoids, Rectal Conditions.

GENITO-URINARY 175

Prostate Gland, Acute Prostatitis, Chronic Prostatitis, Seminal Vesicles, Varicocele, Impotency.

HEAT STROKE 180

DEPARTMENT OF OPHTHALMOLOGY 183

Examination of the Eye, Ciliospinal Center, Somatic Reflexes, Accommodation in the Eye, The Ophthalmoscope, Diseases of the Eye, Neuralgia, Diseases of the Eyelids, Lachrymal Apparatus, Conjunctiva, Ophthalmia Neonatorum, Trachoma, Phlyctenular Conjunctivitis, Vernal Conjunctivitis, Diseases of the Cornea, Examination, Ulcer, Xerosis, Keratitis Neuropatalytica, Pannus, Phlyctenular Keratitis, Interstitial Keratitis, Diseases of the Iris and Ciliary Body, Diseases of the Choroid, Glaucoma, Diseases of the Lens, Cataract, Diseases of the Retina, Optic Neuritis, Optic Atrophy, Asthenopia.

DISEASES OF THE EAR, NOSE AND THROAT 236

Examination, Diseases of the Auditory Meatus, Diseases of the Middle Ear, Acute Mastoiditis, Chronic Mastoiditis, Otitis Media, Catarrhal Deafness, Normal Hearing, Diseases of the Middle Ear, Diseases of the Nose, Rhinitis, Hay Fever, Sinuitis, Epistaxis, Diseases of the Nasopharynx, Adenoids, Diseases of the Oropharynx, Tonsillitis, Tonsillectomy, Quinsy.

MENTAL DISEASES 282

Dementia Praecox, Delirium, Confusion and Stupor, Manic Depressive Psychosis, Involutional Psychosis, Senile Dementia.

DEFECTIVE CHILDREN 303

Tendencies, Amentia, Treatment.

POST-OPERATIVE TREATMENT 312

Vomiting, Backache and Headache, Neuritis, Phlebitis, Nephritis, Pleurisy, Pneumonia.

PART FIRST

INTRODUCTION

What Hippocrates was to the Allopath, what Hahnemann was to the Homeopath, Andrew Taylor Still is to the Osteopath, and it is safe to say that when another century shall have rolled away, his fame will be equal to that of either. That he is a maker of history, even the most skeptical will admit. His teachings are revolutionary but are borne out in fact, and on that as a foundation, is built the superstructure of the young therapeutic giant—Osteopathy.

It would be of great interest to trace the history of the first inception of the thought that drugs were not only unnecessary but harmful, then view the struggle to grasp something tangible to take their place, then see the development of the idea that the human body has within it all that is needed for its upbuilding and repair until he came to this fundamental: "The power of the artery must be absolute, universal and unobstructed or disease will result. The moment of its disturbance means the period when disease begins to sow the seeds of destruction in the human body; and in no case can it be done without a broken or suspended current of arterial blood," capped by the epoch-making discovery of the cause for this interrupted flow of the blood stream—the theory of obstruction by anatomical displacement. It is the only theory of the etiology of disease that will stand the test of science and its acceptance and practice means a revolution in the field of therapeutics.

As it is, he sets the exact date, June 22, 1874, when the light dawned and he saw the outline of his great philosophy—Osteopathy. Then came the years of adversity and struggle. With the eye of a prophet he saw the future of that philosophy, and with the firmness of a Spartan has defended it since birth. It must be a separate, distinct system. Outside the fact that it was to heal the sick and was founded on a knowledge of anatomy and physiology it had nothing in common with existing schools, and if it were ever to grow it must be alone, for his brother practitioners would have none of it and if left to their tender mercies it would have "died a-borning." Even had it been taken up the result would have been the same for they would never have fully developed it. And so through the lean, terrible years he struggled, buoyed by the faith of a discoverer, urged on by love of this child of his brain, fanatical in his determination to win. And win he did for it was vouchsafed to him in his vigorous old age to sit on his hearthstone and see the results of his work, his struggle and his faith. It is something to know that his fame has circled the earth, to be honored and sung by millions; a boon not accorded many a sage or philosopher. Not only has the public accepted it but the medical profession is making tardy but forced recognition of certain cardinal principles of osteopathy by using them, but, of course, without credit.

Osteopathy has been defined as "that science or system of healing which emphasizes, (a) the diagnosis of disease by physical methods with the view of discovering, not the symptoms but the cause of disease in connection with misplacements of tissue, obstruction of the fluids and interference with the forces of the organism; (b) the treatment of disease by scientific manipulations in connection with which the operating physician mechanically uses and applies the inherent resources of the organism to overcome disease and establish health, either by removing or correcting mechanical disorders and thus permitting nature to recuperate the diseased parts, or by producing and establishing antitoxic and antiseptic conditions to counteract toxic and septic conditions of the organism or its parts; (c) the application of mechanical and operative surgery in setting fractures or dislocated bones, repairing lacerations and removing abnormal tissue growths or tissue elements when these become dangerous to organic life."[1] In a word, osteopathy is adjustment and the osteopath is an anatomical engineer who knows what is wrong and has the ability to correct it. Dr. Still changed diagnosis from guess work to fact and on it his fame may well stand, for when the cause of the disease was found, treatment was easy. He has ever emphasized the necessity of thorough examination and correct diagnosis. All treatment must be based on the definite, specific object to accomplish certain definite, specific things.

"Osteopathy would expound and apply the true philosophy of manipulation. While the hands are used, it is not this alone and chiefly that distinguishes its method of operation, but the idea and purpose that lie behind manipulation."[2]

All manipulators are not osteopaths any more than all butchers are surgeons. The need for deep study of the subject is apparent from this characteristic statement of Dr. Still's: "Osteopathy is a science; not what we know of it, but the subject we are working is deep as eternity. We know but little of it. I have worked and worried here in Kirksville for twenty-two long years, and I intend to study for twenty-three thousand years yet."[3] This brings us to the point of the relations of osteopathy with other manipulative forms of treatment. They are not many, for Gerdine,[4] in closing a long article on the "Physiological Effects of Mechanical Therapeutics"

says: “I have striven to show that in no way is Osteopathy similar to massage either in theory or practice if Osteopathy is conceived of, according to its founder, Dr. A. T. Still, as a system of healing in which a definite lesion in form of a bony displacement is the causative factor and a removal of the same, the curative factor in disease.”

The fact that use is made of the hands to the extent it is by both osteopaths and masseurs or Swedish movement operators gives rise to the mistaken idea of similarity in treatment.

“The essential distinction,” says G. D. Hulett, “between Osteopathy and all other systems of healing based on manipulation, clusters around the etiology of disease. While these other systems, as indicated at least by their practice, look at disease from a peripheral standpoint, osteopathy views it from a central standpoint.”[5]

Massage is a small branch of manipulative therapeutics, but conceding that it is perfect and scientific it can only resemble osteopathic treatment in one ramification of osteopathic practice, viz: relaxation of muscles.

The fact that massage is often employed by osteopaths in connection with their work shows the limitations of that form of treatment. Says McConnell[6]: “In the human body, as in any delicate, complicated mechanism, there is mechanism within mechanism; and, in order to obtain certain mechanical effects, many times there is required a series of complicated movements, all of which bear a ratio one to the other according to the energy utilized and the mechanical principle involved.” No other form of manual treatment takes this principle of mechanics into consideration. It is possible, as Gerdine points out, for an undeveloped osteopath to practice massage under another name. That the two should be confounded before the public is due to his ignorance and not from any fault of the system. Massage is a valuable aid in the treatment of disease but it is not Osteopathy.

“In the bright lexicon of osteopathy there is no such word as rub[7].”

Osteopathy in its relation with medicine has little in common. From the beginning, its founder realized their paths should run divergently, so the first step, its teaching, must be considered from a different viewpoint. To quote from an address by Teall[8]: “But to adequately teach osteopathy a vast amount of original work must be done. Anatomy is anatomy but there is a vast difference in its application. Physiology must be taught to mean something more than an interesting phenomenon. Pathology has an unfilled gap between cause and effect which must be bridged. The post-mortem has a great story to tell but an osteopath must tell it. A slide of degenerated tissue under the microscope is of interest, but why the degeneration? It is described at length by the authorities, but the reason for the causes and morbific changes are not carried out. Obstetrics along strictly natural and physiological lines insuring both mother and babe against injury; gynecology, minus the knife and plus common sense; all these, and more must be put into shape to teach the osteopathic student. The archives of osteopathy were empty ten years ago. There was no precedent to follow and the ideas in teaching which had prevailed for centuries dominated. All this is changed. The colleges teach the science along strictly osteopathic lines, making the application of the truths which have escaped the notice of centuries of investigation.”

All schools recognize the wonderful recuperative power of nature, as this from the introduction of a standard allopathic text book will show[9]: “There is no scientific dogma better established than this: that the living organism is in itself adequate to the cure of all its curable disorders. This natural law sustains the medical skeptic in his infidelity, enables the homeopath to report his sugar cures, and helps all physicians out of more close places than they are generally willing to acknowledge.” But at times, as all will agree, nature is not able to overcome its maladies and assistance is needed. Here, again, is a divergence as to the method and character of that assistance. There is no system so trivial or absurd which cannot point to its cures, but a school of medicine should have a settled system with established methods of procedure. This is not true of any school employing drugs as its principal therapy. In the President’s annual address at Cleveland he says[10]: “The observant reader of the progressive medical press is struck at once by the unsettled condition in the field of modern therapeutics. The trend is emphatically away from drugs. But, in the effort to get away from medicine, the medical investigator has wandered far afield, cutting loose from nature and resorting to the artificial.” It is the last paragraph of the extract quoted which particularly emphasizes the point of divergence, natural _versus_ unnatural methods. It must be understood at once that the osteopath admits the reality of drug action for “there is no doubt that the pharmacopeia records many drugs whose action is rapid and effective so far as securing activity or decrease of secretion is concerned, but the element of danger, i. e., their destructive power is great. Oftentimes their power does not stop at the point desired or limit its effect to the therapeutic action sought[11].” This point of unreliability of the drug is emphasized by the following from recognized medical authority[12]: “We give drugs for two purposes: (1) To restore health directly by removing the sum of the conditions which constitute disease. Here we act empirically with no definite knowledge—often indeed with little idea of the action of our drugs, but on the ground that in our hands or in the hands of others they have restored health in like cases. (2) To influence one or more of the

several tissues and organs which are in an abnormal state so as to restore them to or toward the normal; with the hope that if we succeed in our purpose recovery will take place. The purpose we effect by means of the influence which the chemical properties or drugs exert on the structure and function of the several tissues and organs. Minute information, therefore, of the nature of drugs and their action is essential for their proper employment." Osteopathy brings into action the latent or stagnant forces of nature by specific methods which are usually reliable. Naturally there being such a wide difference in theory of the cause of disease it would be also shown in diagnosis as well as treatment. The most striking points to the layman in medical procedure are: first, wide difference in the system of diagnosis and in its findings by physicians of the same school; second, the great variance in remedies employed by different physicians of the same school for the same disease.

Osteopathic diagnosis is so physical in its character, depending upon actual conditions found and not upon the subjective symptoms alone, that the same patient examined by a number of experienced osteopaths will be given the same diagnosis, and he will also be able to detect in each the same effort to correct in all their technique. All the methods of physical diagnosis are used plus the distinctive osteopathic procedure. Results wherever used bear out the effectiveness of the system.

The osteopath must and does consider the necessity of surgery, but his effort is always to prevent the operation if possible. There can be no doubt that surgery is carried to extremes and there is a strong sentiment growing that much of it is unnecessary. Says Homer Wakefield, M. D.[13]: "It is to the everlasting disgrace and mortification of the medical man that the wealthy classes who are continually under the observation and direction of eminent men, in dietary, and all life habits, in health as well as in sickness, are not only the very ones who develop appendicitis and most largely go to operation, but are almost exclusively those who attain to this distinction." The operations of today are wonderful and the surgeon shows great skill and genius in their performance, but great as he is in these matters how infinitely greater is the man who can prevent them. The need of the osteopath today is to be trained to recognize surgical conditions and neither allow surgery unnecessarily nor make the more terrible error of not acting soon enough. Where surgery is a necessity there is always an etiological factor to be considered. The cause of the manifestation not always being removed what is to prevent a recurrence or serious sequela in spite of the operation? "The specialist ... if he has wit enough to read the lesson presented to him, that it is not sufficient to remove an ovarian tumor, e. g., and that if nothing is said at the same time or subsequently as to the causes which induced it, a positive damage may be done to the woman, who may, therefore, while considering herself cured, proceed to manufacture one on the other side, or may find herself in a few years suffering from cancer in the stump of the previous one[14]." And so the combination of osteopathy with surgery may be necessary that the cause shall be removed. Osteopathic treatment before operations in reducing congestions and inflammations, also in toning the nervous system, is particularly efficacious while the after treatment gives gratifying results. In fact, the two go hand in hand when conservatism rules both.

That diet should receive particular attention from the osteopath is not strange, for his veneration of nature peculiarly fits him to realize the necessity of correct feeding. Probably no subject is more discussed or presents a wider range of opinion than diet. There is overfeeding and underfeeding; long intervals and short between feedings. There is the no breakfast and no supper plan, mixed diet and the vegetarian, uncooked foods, and one exclusively of milk, anything you want so long as you are hungry but chew it well, etc., ad. lib. All are represented by osteopaths in their following as they are from other professions, but probably this would more nearly represent the views of them as a school. In health, first, most people eat too much and do not thoroughly masticate and insalivate. This applies to all stations of society. Second, meat forms too large an item in the daily dietary. Third, there is not enough variety and the ration is not well balanced as to elements. Fourth, not enough care is used in preparation of foods. In illness, first, the stopping, complete or partial, of food until the system can take care of it; second, the giving of easily digested foods. The man who avoids violent extremes in diet as well as in other habits of life will usually last longest. It is to be hoped that some rational system can be evolved on which all factions may agree, for the present confusion of authorities is bewildering. The osteopath gives attention to hygiene, sanitation, exercise, environment, mental attitude, etc., as they may affect the welfare of his patient.

Osteopathy can cure all curable diseases, for the same forces which will overcome one malady will overcome another when set in motion. Forces that produce a diseased condition will it normalized restore the established type.

OSTEOPATHIC ETIOLOGY AND PATHOLOGY

Osteopathic Etiology

Osteopathic etiology and pathology constitutes the most interesting chapter of osteopathic science. The primal divergence of the osteopathic schools from previous systems is to be found in the osteopathic interpretation of disease causes and processes, and not in osteopathic therapy as some may think. Osteopathy makes claim to an independent school because it possesses a distinct etiology, pathology, diagnosis and treatment. Thus osteopathic practice is not a mere method, but instead a system, a school, a science.

At no period of medical history have physicians of the older schools felt more keenly the futility of medical methods and the lack of an all-embracing principle of medicine than at the present. A recent writer[15] who claims to have discovered a principle that encompasses the entire field of medicine, says: "We found, we may say, that the backbone of medicine was the absent factor, and that if the patient labors of so many great minds had not proven as useful in the development of practical medicine as they should, it was because they lacked such a fundamental framework to afford a fixed _nidus_ for each discovery, wherein its true relation to other discoveries would at once become evident."

Since the conception of osteopathy its fundamental framework has not changed one iota as to principle, although the application of the principle has been greatly elaborated. When Dr. Still proclaimed that "the rule of the artery is supreme" he gave utterance to a basic physiological truth. But when he demonstrated that osseous and other anatamo-mechanical lesions disturbed the artery and caused disease, and that readjustment of the anatomical cured the disorder, thus allowing the physiological to potentiate and revealing that the living body contains all the attributes of a vital and physical mechanism, did his teaching contain the germ of a comprehensive philosophy; this gave osteopathic science a "backbone" with a consequent fixed _nidus_ for all existing facts and future discoveries. And thus, it should always be emphasized that mechanical readjustment of the component parts of the vital body is the eternal keynote of the osteopathic school of healing.

=The Osteopathic Lesion.=—Broadly speaking a lesion is "any morbid alteration in a tissue whether attended by a recognizable structural change or not; but especially a change in which the continuity of some of the tissue elements is broken in upon.[16]" There are several kinds of lesions expressing the tissue involved, character of degeneration, locality of same, etc. But upon analyzing the medley of arbitrarily defined lesions the fact will be evident that much of medical etiology and pathology has not been logically and consistently sifted and arranged; and moreover, it will be found the =cause of causes= of many diseases is unknown.

Herein, arises the great significance of the osteopathic lesion, for the lesion alters the very governing and controlling tissues of the body, viz., the nervous tissue and the vascular channels. Hulett[17] defined the osteopathic lesion as "any structural perversion which by pressure produces or maintains functional disorder." The constant maintenance of the structural perversion will, also,

cause organic disease, although it is granted that functional disorder must necessarily result prior to any organic change.

The osteopathic conception of a lesion, functional and organic disorder caused by pressure from disturbed structures, does not bring us into an absolute new field. Medical literature of all ages contains references to diseases caused by pressure of tissues on nerves, blood vessels, or other channels. But the osteopathic idea is an absolutely new one in the application of this principle universally. It simplifies and makes uniform the arbitrariness of present semeiology.

Thus the osteopathic idea that many diseases originate, primarily, from anatomically malaligned, malpositioned, or malrelated tissues causing a blockage of vital processes, immediate or remote, is a theory inclusive of disturbances to all tissues. This principle is fundamental and is supported by the physiological truth that uninterrupted vital channels preserve health; moreover clinical and experimental data, as will be shown later, substantiate this fundamental. It at once places interpretation of a lesion in an entirely new light from preconceived concepts, and is analogous to and co-extensive with etiology and pathology.

=Etiological Factors.=—The osteopath believes in the potency of inherited and environmental influences. There can be no question that a few diseases and certain disease tendencies may be inherited, the principle feature, however, from the standpoint of heredity is, various organs and tissues have less vital resistance. These should not be confounded with congenital weaknesses and diathetic tendencies.

Environmental influences are very important factors. One's surroundings and daily habits in the home, shop, or office count for much in the aggregate. Food, drink, air, rest, sleep, clothing, exercise, mental attitude, etc., are all factors in the sum total of health, and consequently ill health may be traceable to their abuse. In fact, all hygienic and sanitary measures are duly considered by the osteopath. Various abuses, over use, and disuse of the functions will certainly be followed by physiological discord.

The germ theory contains much truth, but in the very large percentage of cases where the micro-organism is a factor its significance is only of secondary consideration. Immunity and resistance comprise an important part of the health problem, of which the intact anatomical is of first consideration. Usually the micro-organism plays the role of an exciting and determining factor; before it can multiply and grow there must be a field that is first nutritionally disturbed. Nutrition of the tissue is the one great point always to be considered. The constitution of an individual is the pivot about which predisposing, environmental, and exciting factors of disease center. Health represents the integrity of the artery as well as a maintenance of that master tissue, the nervous system, and anything that produces or influences, directly or indirectly, a disturbance of physiological functioning borders on the pathological.

Hence the osteopath recognizes many of the common medical causes of disease, but reserves the privilege of rearranging their relative positions, for the osteopathic cause of disease greatly modifies their value.

=Osteopathic Etiology= distinctively emphasizes structural derangements and perversions. Of =first= importance, owing to static requirements, is the =osseous lesion=. This lesion is represented by any abnormal change of position or relation of the many bony constituents of the body. The framework of the body is subject to not only any and every physical violence of any mechanism, but moreover being the corporeal foundation of a vital mechanism is subject to both direct and indirect biochemic changes and influences.

Thus the osseous lesion is caused (a) by traumatism, e. g., strains, falls, blows, etc.; (b) indirectly by atmospheric changes, over and violent exercise, the slumped posture, debilitating habits, etc., through the media of muscle changes and imbalance; (c) by nutritional effects disturbing the elements of bony tissue; (d) by ligamentous change such as thickening of a capsular ligament; (e) by infections; (f) compensatorily and reflexly through the media of body distortions and muscular irritability or debility, e. g., an innominate lesion may be compensatory to a lumbar curvature, dietetic errors may cause dorsal muscular irritation and contraction produce a constant osseous lesion which in turn may result in chronic indigestion.

The pathological changes in the osseous lesion are commonly one of structural derangement, deviation or complete displacement. The vertebral segments are of primary consideration owing to their important relations to the spinal nerves, spinal cord centers and sympathetics; the ribs owing to the close sympathetic and spinal nervous relations; and then other osseous tissues, as the innominata, clavicles, etc., depending upon their importance to contiguous vessels, nerves and organs. It should always be remembered and emphasized that mechanical changes of the anatomical structures is the primary essential in osteopathic etiology; this is the one great inception of pathological variations from the distinctively osteopathic conception, which the osseous lesion typifies. Consequently the osseous lesion factor is actually a luxation (complete, or partial, even to a very slight degree), or

malalignment of the bony constituents, which by virtue of their physical malposition impinge or irritate contiguous tissues. The essential test is the functional one, movement. The degree of involvement may be one of many gradations ranging from a slight malposition or impaction to a marked deviation or firm anchorage.

=Second= in importance from the static requirement of support is the =muscular lesion= though from the standpoints of movement and dynamics it is often of the first consideration etiologically. Many interosseous lesions are the result of spastic involvement of deep seated spinal muscles, of fibrotic changes and of tensions and weaknesses that either establish a rigidness of the segments, compromising nervous stimulus or vascular channel, or produce an imbalance of muscular tone and tension. In the latter instance some type of sidebending-rotation osseous lesion occurs, commonly anchored within the physiologic movements of the spine. The muscular lesion may be an actual dislocation of either muscle or tendon, but rarely. Commonly it is a contracted, or tensed, or contractured muscle. The muscle, also, may be diseased either from primary or secondary causes through nutritional and infectious sources and thus be an etiological feature.

The muscular lesion is caused, (a) by direct or indirect violence the same as the osseous lesion; (b) by atmospheric influences; (c) by slumped posture, debilitating habits and various errors of living; (d) infections; (e) by reflex irritations; (f) by compensatory changes; (g) by disease causing hypertrophy or atrophy; and, (h) secondary to osseous lesions, being the result of impingement to the muscles' nervous control. The tensed or stretched muscle may result from a separation of the points of origin and insertion.

Herein the fundamental osteopathic concept is the resulting affection due to the physical encroachment, directly or indirectly, of the muscle tissue upon vascular channel or nerve fibre, or the effect upon the movement or alignment of the osseous tissue.

Muscular contractions, displacements, and tensions play a most important part in acute disorders, although muscular lesions that are secondary to other lesions are usually taken into account when treatment is given. Muscular lesions affect, (a) blood and lymph vessels; (b) nerve fibres. Muscular contractions, especially, impede mechanically the return of the venous blood to the heart. The lesions to the nerves may be manifested in innumerable ways, depending upon the location of the muscle and the function and distribution of the nerve affected.

Then there is the relaxed, overstretched, and atonied muscle. This condition results as a secondary effect to mechanical strains, these being so severe and constant as to cause direct stretching and possibly tearing of the muscle fibres. This should be distinguished from the exhausted or debilitated muscle, e. g., as found in neurasthenia and anemia.

Diagnostically there are, (a) contractions of more or less area, due to atmospherical changes; (b) the deeply seated contractions involving a very small area, caused by vertebral and rib lesions; (c) contractions due to reflex disturbances; (d) contractions caused by postural effects and deformities; (e) contractions from spasms of the blood vessels as a result of nervous irritations; (f) contractions due to toxicity of the blood. All of these characteristic muscular lesions give a direct hint as to both etiology and prognosis.

=Third=, the =ligamentous lesion=, as a lesion _per se_, is usually of secondary importance to the osseous lesion. In chronic cases affections of the capsular ligament and muscular fibrosis commonly maintain malalignment or rigidness. There are two features that should be noted in particular when considering this lesion; first, thickenings and adhesions; and, second, relaxations.

The tone and integrity of the ligaments cannot but be of vital concern to the stability, suppleness, and adaptability of the bony framework in all physical movements. No matter how slight the osseous lesion may be the ligament must of necessity be involved. The osseous derangements are either a source of irritation to the ligamentous tissue, resulting in congestion and inflammation and hence thickening and adhesions, or else the ligaments are so strained and tensed that in time atony may occur. Probably, in a fair percentage of atonied cases the first disturbance to the ligament is one of irritation and congestion, and from long continued involvement irritation is supplanted by debility.

Consequently the primary consideration of the ligamentous lesion from the etiological standpoint is the character of the tissue (ligament) changes. This, also, gives us a direct hint that is of the utmost value in prognosis. The independent displacement of a ligament is rare, thus ligamentous lesions from the viewpoint of purely physical displacements are secondary to if not an actual part of the osseous lesion. Ligaments, when displaced or tensed, readily impinge or irritate contiguous tissues, but the original cause of the structural perversion is commonly either the osseous or muscular lesion. Hence, whatever factors enter into the production of these lesions will at least indirectly produce the ligamentous lesion.

=Fourth=, the =visceral lesion= is frequently overlooked as being of much moment as an osteopathic lesion. Visceral displacements acting as a source of functional and organic annoyance on the physical plane (structural perversion which produces and maintains pressure) alone are not in the least uncommon.

Any or all of the abdominal viscera, or even the organs of the thorax, may be displaced (physically) pathologically. Actual displacement of the viscus is a prolific source of distinct disorders and many obscure symptoms. True it is the organs are most frequently displaced from indirect causes, but nevertheless the actual physical malposition is in turn a primary cause of still another train of symptoms and diseases.

Visceral lesions are caused by, (a) vertebral lesions; (b) postural defects; (c) direct violence; (d) nutritional disorders; (e) childbirth; (f) unhygienic measures (tight lacing, heavy skirts, etc.); (g) congenital weakness.

From the displaced heart due to valvular and debilitating influences to the displaced liver, the stomach, the kidneys, the intestines, the ovaries, and the uterus, may arise a source of direct or indirect irritations, a train of apparent or masked symptoms, or a group of nutritional disturbances that include an extremely important chapter in etiology. Moreover not only may one organ alone be involved but several may be displaced or prolapsed as a whole as in splanchnoptosis; and even these in turn may be the direct cause of further organic displacements as the abdominal viscera prolapsing upon the pelvic organs. Here is a very fruitful field for the diagnostician, for to separate cause from effect requires keen perception, an acute sense of touch, and above all, most careful weighing of all the factors that enter into the maze.

=Fifth=, the =composite lesion= is not always recognized as an extremely important osteopathic factor. By composite lesion is meant a structural lesion that primarily includes the osseous, muscular, and ligamentous tissues as a whole. This may be termed a lesion _en bloc_ or _en masse_.

Composite lesions are of exceedingly frequent occurrence. Indeed, many composite lesions are overlooked and instead of treating the _en bloc_ disturbance as a consistent whole the component factors are treated separately with no concern or attention to the whole.

Postural defects are excellent types of the composite lesion. The various curvatures, the tilted pelvis, etc., are representative of the composite lesion. Etiologically, pathologically, diagnostically, and therapeutically the contour of the spine and ribs, the relation of the innominata to the sacrum and spine, and the symmetry of the body generally should be recognized and appreciated. The relation of the part to the whole and of the whole to the part are of vital etiological concern. An incipient curvature may be easily overlooked, a pendulous abdomen neglected, and a slipped innominatum passed unnoticed wherein as a result the entire vertebral column is malaligned in relation to the physiological curves or to the perpendicular line of gravity.

Frequently attempts are made to correct individual lesions when attention should be directed to the composite lesion and _vice versa_, e. g., a displaced rib is usually dependent upon a corresponding vertebral lesion, and thus the transverse plane or section of the body should be considered as a whole. A single lesion may be dependent upon a composite lesion or a composite lesion dependent upon one or more single lesions. A slipped innominatum or a disordered hip joint may bring about a strain to a greater or less section of the spinal column, or a twisted vertebra may cause a curvature, whereas on the other hand postural defects may cause a strain at its maximum focal point resulting in over-stretching and relaxing of ligaments so that an osseous lesion results, or a spinal curvature cause an innominatum displacement. Thus there is a constant establishing of equilibrium, physically and physiologically, through the medium of compensation, but at some phase of the change there are apt to be pathological phenomena resulting, and very frequently physiological harmony is not reestablished but instead irritation, debility and other disease symptoms are constant effects until relieved.

Consequently osteopathic etiology is many sided and complicated. To know whether an osseous, ligamentous, muscular, visceral, or composite lesion is primary or secondary, compensatory, reflex, predisposing, or exciting, requires a command of theoretical knowledge backed by much actual clinical experience.

In noting the above distinctive osteopathic etiologic features the student should not lose sight of the constitutional status of the patient which may be modified by inherited, congenital, diathetic, and environmental influences, all of which go to make up the predisposition of the individual and have an important relation to osteopathic factors. Then it should be recalled that disease processes may be of insidious progress, and the products and effects of pathologic changes accumulative.

Osteopathic Pathology

In the etiologic study the osteopathic characteristics have been designated structural maladjustment, although at the same time not losing sight of the angle that the body is not only a physical mechanism but also a vital organism. Structural perversions characterize the osteopathic distinction when dealing with the physical body, and remembering the vital or biochemic mechanism, mental attitude, diet, hygiene, etc., are not forgotten. To retain or attain health, thorough appreciation of both the physical and vital mechanisms should be kept in view, for there is both an independent and dependent interaction on the part of each. The living body being an entity premises a system of therapeutics both physical and vital, that acts in direct accord and harmony with physical laws and physiological functioning.

Osteopathic pathology deals with the distinctive osteopathic lesion as a factor in production and maintenance of disease. Then the province of pathology is, first, to determine whether the lesion is in reality an etiologic factor; second, the immediate character of the lesion disturbance; and, third, how organic life becomes involved.

Inspection, palpation, clinical results, dissection and laboratory experimentation include the methods employed to prove that the lesion is of practical consequence. That the lesion is an etiological factor can be known only through clinical and experimental proof; the immediate character of the lesion disturbance can be determined by dissection; and how organic life becomes involved requires the summation of histological, physiological and pathological data.

The following outline assumes that the reader is familiar with anatomy, physiology and pathology. Osteopathic pathology does not add to medical pathology an absolutely new pathology in all of the present known numerous details, but instead interprets much of clinical pathology anew, and furthermore it presents absolutely new data that is exclusive, but germane to the present general medical and surgical fields.

Nervous tissue and arterial blood are the master tissues, the controlling and governing factors in health, and disturbances of these tissues are necessarily the cause of ill health. The rule of the artery and the control of the nerve must continue uninterruptedly in order that physiological functioning remains intact. The body should be looked upon as a being complete, no more or less, each tissue and organ essential to the whole and the organism as a whole essential to every part. This is fundamental and germane to a living structure, and hence disturbance to the governing and controlling tissues, the nerves and vascular channels, must necessarily cause a break in the concatenation and disease must logically follow.

Thus in the osteopathic pathology we look to those influences that primarily disturb the nerve or artery, study the disease process or extension from inception to effect and from primary lesion to morbid results, and note action and interaction of tissue upon organ and organ upon organ.

That all parts of the body are in intimate and dependent relations each with the other through the media of the nervous and endocrine systems is a well known fact based upon histological and physiological grounds. The neurone being the physiological unit implies that any disturbance to the cell quickly disturbs any or all of its processes. It may be said that “nervous tissue is dependent for its integrity upon two things, blood supply and trophic influences. The nerve cell is solely dependent on a proper supply of blood, and dies when this is withdrawn. But the nerve fiber is more dependent on the trophic influence of the cell of which it is a prolongation. It dies when cut off from the cell but it can get along for a time with but little direct blood supply. On the other hand, if the nerve fiber is injured it reacts on the cell, leading to a partial but curable degeneration of the cell body.”[18] Here is the immediate pathologic key to many diseases. Whatever cuts off or obstructs the artery leading to the cell is a primary etiologic factor; this then leads to degeneration of protoplasmic processes and axone. It should be carefully noted that if the obstructed blood vessel is one to the nerve fiber only the resultant partial injury to the cell is curable.

“When an axone degenerates the retrogressive process involves not only the main axone, but also its terminals, together with the collaterals belonging to it with their terminals.”[19] This is an exceedingly important link in the explanation of osteopathic pathology, that distant organs may be affected by the osteopathic lesion. Moreover, “degenerations of a secondary character may occur in those systems of neurones which are more or less dependent upon the peripheral sensory neurone system for their impulses.”[20] This is equally true with the central motor neurone, or any neurone. It shows how far-reaching a degenerative process and its effects may be. It further makes clear that nerve intactness is directly and absolutely dependent upon a normal circulation, and that it is self-evident any blockage either to blood vessels or to neurones will vitally affect those tissues that govern and control the life processes of the body. The integrative action of the nervous system is one of the outstanding facts of physiology.

The above is presented so the student may see how osteopathic spinal lesions, if deeply seated and effective enough, can involve remote tissues and organs. No one will doubt that fractures and complete dislocations of the spinal column will seriously affect

visceral life, or a prolapsed kidney will be a cause of nutritive disturbance, or a displaced uterus the cause of ovarian congestion, or a dislocated hip the cause of atrophy of the leg muscles, but it has remained for the osteopath to offer proof that slight misplacements of the vertebræ or ribs, incipient curvatures, postural defects, slight deformities, and unsymmetrical bodies are of sufficient etiological importance on the physical plane to affect neurone integrity and obstruct artery courses, and thus organic life.

The question at once arises, what is the immediate or direct effect upon blood vessel or nerve of the osseous, ligamentous, muscular, visceral or composite lesion? The osseous lesion will be taken as a type. The direct effect is usually one of hyperemia or ischemia, generally the former, for as physiologists and clinicians observe irritation commonly precedes debility. In the vertebral and rib lesions there may be direct pressure upon the spinal nerve at its spinal foramen exit or on the sympathetic chain directly contiguous to the heads of the ribs. This causes congestion, inflammation, ecchymosis, and degeneration of the nerve fiber, followed by macroscopic and microscopic changes as connective tissue proliferations, arterial scleroses, etc. Or, as seems probable in experimental work, the inception of the pathology may be frequently the result of blockage to nervous stimuli, which when maintained affects the efferent vasomotor, secretory, trophic and other fibers so that circulation and nutrition are definitely involved.

Thus the cells so sensitive to altered vascular changes are directly and remotely affected, and disease characteristics dependent upon structure and function of tissue, and degree of irritant are evident. This can vary, in degree only, with the muscular lesion that involves collateral spinal cord circulation, the visceral lesion that irritates sympathetic life, or the composite lesion that deforms or perverts structure en masse.

But is the physical noxa as potent an etiologic factor as the chemical or bacteriologic? Adami[21] informs us whether an irritant is physical, bacterial or chemical, no satisfactory distinction can be founded on the duration of the irritation; that a local irritation of the nervous system may lead apart from “direct reflex action, to changes of nervous origin, in the region of the injury and in the reflexes affecting associated regions, the higher centers; and through them the system at large, may become affected by paths that it is not always easy to trace.” Again he says that “centrifugal impulses alone, apart from any local injury, may originate a succession of phenomena of inflammation in a part.” And “in all probability a nervous and central origin must be ascribed to some, at least, of the sympathetic inflammations seen to occur in areas supplied by the other branches of a nerve supplying a part primarily inflamed; and again in areas supplied from the same region of the brain or cord as the inflamed organ.” Other inflammatory changes, of course, may occur independently of centrifugal nervous influences, and the vessels react independently of central influences.

This, then, presents a situation postulated thus:

1. The body follows definite structural relations and is influenced by mechanical arrangements in its morphology.

2. The integrity of tissue depends upon structural freedom of nutritive courses.

3. The above predicates a structural etiology as exact and precise as structural relations are important to nutrition.

What proof, then, of the foregoing have we to offer?

First, the =clinical proof=. Clinical results have been obtained in tens of thousands of cases that include disease of various types and lesions, and of all sections and organs of the body. The art of osteopathy has been perfected in many of its details, based upon actual experience and splendid results. The cure of the patient is paramount to all other consideration, and whereas the osteopathic school has been shown a superior system it logically follows on _a priori_ grounds that relief and cure of suffering is of the first and final importance.[22]

Were it not for clinical results no new system of therapeutics could withstand criticism and calumny and finally triumph and be publicly, legislatively, and scientifically recognized.

Second, the =autopsy proof=. Many dissections have been made and autopsies held with the view of discovering the character and the potency of the osteopathic lesion. This very important work has borne out the osteopathic theory of disease. Vertebral and rib displacements have been noted, corresponding ligamentous tissues thickened, associated nerve tracts and vascular channels disturbed, and finally the related organ found diseased.[23]

Third, the =experimental proof=. Experimental proof appeals, logically, to the scientific mind. This proof[24] is being gradually developed.

Experimental investigation has been successfully carried out upon numerous animals. The experiments conclusively prove that not only spinal inhibitory and stimulatory manipulations (mechanical) are productive of immediate physiological changes in the viscera, but that the structural anatomical lesion or noxa is an important factor in the etiologic field. Pathological changes in several organs directly follow the artificially produced vertebral and rib lesions, showing beyond doubt the reality and effectiveness of the osteopathic lesion. This emphasizes the point that centrifugal impulses originate an inflammation in a previously healthy and uninjured tissue or viscus. And as “inflammatory phenomena may be sympathetically developed in regions innervated from the same area in the brain or spinal cord” it remains to prove the actuality of vertebral and rib lesions, i. e., structural perversions really affect contiguous nerve courses and vascular channels; and this has been demonstrated in laboratory experiments and at the autopsy. Consequently the vertebral, rib, or other lesion may be an important etiologic factor either to the nerve strand from cord or brain to viscus or from viscus to cord or brain.

Dr. Still says in his Autobiography that “all nerves depend wholly on the arterial system for their qualities, such as sensation, nutrition and motion, even though by the law of reciprocity they furnish force, nutrition and sensation to the artery itself.” It matters little in this outline whether obstruction to nervous integrity is by way of an impinged artery or by direct pressure, or both, or otherwise, for the primary consideration is the noting that the osteopathic lesion is a real and potent factor of disease. Sajous[25] informs us that “a neurone is directly connected with the circulation (via neuroglia-fibril) by one or more of its dendrites, which serve as channels for blood plasma,” that a neurone receives its nutrition directly from the general circulation, and that from the axone the blood passes into a lymph space connected with a vein. Thus in reality a part of the circulatory system is that of the entire cerebrospinal system.

The student is referred to the various publications of the Research Institute and Deason’s Physiology for experimental data confirming the validity of the osteopathic theory, although it should be emphasized that clinical evidence is quite conclusive. Malalignment injuries of the vertebral articulations, for example, ranging from imbalance of muscular tension to infections, is certain to result in some type of rotation and sidebending of the segments to an extent that apposition is compromised and abnormal anchorage supervenes. There are many factors of the pathology: muscular tension and fibrosis; damaged ligaments, particularly the capsular; interference of nervous stimuli, blockage of impulse directly and reflexly as shown by pathologic involvement in cord centers and sympathetic ganglia, and in certain cases direct obstruction of nerve fibers as revealed by Wallerian degeneration; involvement of circulation as shown by damage to blood-vessels, local edema and local acidosis, and effect upon local tissue respiration and drainage. Through a combination of these various factors circulation, nervous equilibrium and chemism of related parts are involved, both anatomical and physiologic balance is upset, and resistance of corresponding viscera affected. Reciprocal innervation and the axone reflex are also disturbed, all of which are important predisposing causes that disturb resistance of tissues and organs, upset their correlated mechanisms and render active various possible infections and toxins that otherwise a normal circulation, nervous and endocrine systems, and oxygen supply would rapidly and successfully combat and restore the organism to normal. Thus from the practitioner’s standpoint there are three points to always keep in mind: readjustment of the lesion; correction of the forces, habits, environment, etc. that produce the lesion; and hygienic attention of the body after lesion adjustment in order that normal condition may be maintained. A thorough study of the physiologic movements of the spine is a prerequisite to an understanding of the various possible abnormal appositions, though it should be appreciated that these movements are not consonant or applicable to many abnormal conditions. Pathology reveals many gradations and combinations not found in normal conditions. Frequently the key of a successful technique rests upon an understanding of the individual make up of the interosseous lesion.

It has not been the purpose of this section to go into details but rather to follow logically an outline of osteopathic etiology and pathology. The various details will be found in the osteopathic works on Principles as well as in the experimental articles referred to. It should be understood that the osteopath believes thoroughly in _vis medicatrix naturae_ whether the indications are for stimulation or inhibition or for the basic readjustment. Generally speaking, however, therapeutic philosophy resolves itself (ultimately) into the principle that a cure depends upon giving an impetus to impaired, habitual and latent forces, which in the osteopathic field implies fundamentally adjustive manipulation whereby the resultant impetus or physiological stimulus is initiated.

In a word, osteopathy premises that the body is a vital and physical mechanism subject to derangements, structural alterations, and functional changes, as results of violence on the mechanical plane, as well as disturbances on the psychic and biochemic planes. Hence, osteopathic philosophy is inclusive of preventive, palliative and curative measure.

OSTEOPATHIC DIAGNOSIS AND PROGNOSIS

Osteopathic Diagnosis

In osteopathic diagnosis the spine is the first and greatest object of interest, for on the result of its examination will depend the treatment to be given which is in turn hoped to bring about recovery.

As it is the structure on which rests the weight of the body the practiced eye is able to detect at a glance, by the poise and gait of the patient, if there is an abnormal condition affecting any considerable area of the spinal column. It is well to observe these points, especially in the female, before having them prepare for examination, as it will often give a clue to sources of trouble through faulty carriage, improper dress, particularly corset and shoes. Slight changes of gait, unnoticed by the patient may be of great aid in determining the beginning of disease in the spinal cord.

No osteopath is justified in accepting a patient who will not permit every examination deemed necessary, as remote and obscure lesions are frequently the cause of disease, so preparation of the patient for the first scrutiny is of importance. This cannot be made with the patient fully clothed, as visual observation is second only to the touch in making one's deductions. Neither can palpation be made through more than one thickness of clothing with accuracy, and examination next to the skin is always preferable. This need in no way ever cause complaint, for with the use of a loose fitting short kimono, with all outer clothing removed except the knit undergarment, and with skirt bands loosed, a complete survey of the whole dorsum from occiput to coccyx can be had without the slightest unnecessary exposure. It is well to remember that the patient has come for help and the osteopath is not justified in sacrificing thoroughness for any exaggerated feelings of modesty. With tact and care in the use of the garments the most sensitive ones need feel no hesitation in coming for treatment.

A complete history of the case should be taken before the examination begins, former methods of treatment, symptoms, environment, etc., as it will aid in the final conclusions. It is well to have blanks for keeping records of all cases.

Probably the most comfortable manner to begin physical examination is to seat the patient on a table squarely with hands placed upon the knees, then raise the garment and expose the whole back. Begin by noting the texture of the skin, if it is clear, pigmented, blotched, or has eruptions. Try the capillary reflex by pinching or stroking quickly with the finger tips or the blunt end of a pencil. Find if it is moist or dry and also outline the areas of changed temperature, if any. Then observe the general contour of the spine with the patient sitting upright, to find how near it is to the normal body curve.

Occasionally having the patient alternately sit and stand will, by comparison, throw light upon the condition. With the patient bending forward place the hands on the crest of the ilia and see if they are of equal height.

Occupation may result in over development of one side or there may be congenital asymmetry[26]. Note position of the scapulæ and habit of posture in sitting and standing.

Before taking up the subject of a critical examination of each vertebra there are certain points it will be well to consider. It is easy to know instantly, without counting, the number of the vertebra causing the lesion if these landmarks are remembered: First, the spine of the third dorsal is on a level with the spine of the scapula. Second, the spine of the seventh dorsal is on a level with the inferior angle of the scapula. Third, the spine of the last dorsal is on a level with the head of the last rib. It will save much time for the busy osteopath to have these well in mind.

The =pathognomonic symptoms= of the osteopathic lesion are: (a) maladjustment; (b) contracted muscles; (c) tenderness; (d) limited movement. To these might be added changes in local temperature and disturbance of function, but the former is not constant and the latter may be remote. Here the primary lesion is considered, for an osteopathic lesion may be, also, secondary or compensatory. Forbes speaks of compensatory changes as being an important diagnostic sign.

Diagnosis of the position of a vertebra is sometimes difficult to the beginner from its having longer or shorter spines than normal. Horsley speaks of the occasional congenital absence of a spinous process. They may be bent laterally, upward or downward and thus have all the appearances of a marked displacement, while occasionally the body itself seems much at fault. These present what might be termed normal abnormalities and make it necessary for the osteopath to be very sure of his diagnosis before attempting to correct what is not abnormal, for disappointment, at least, and injury, perhaps, may follow.

To avoid mistake, carefully palpate the transverse processes and determine if they are at right angles with the adjoining normal spine. In the cervical and lumbar vertebræ it is possible to reach the tips of the transverse processes, and on moderate pressure, if a lesion exists, pain will be elicited. Further, where tenderness is associated with other diagnostic points it can be safely assumed that a lesion exists, and by outlining the suspected vertebra with the finger and localizing the sensitive spot one can be sure of the point of greatest irritation and the character of the displacement. Associated also with these signs will probably be evidence of congestion, such as thickened tissues, contracted muscles, etc.

After having examined the condition of the spinal column thoroughly by inspection, begin at the first dorsal and examine the spinal column down to the sacrum. Place the middle and ring fingers over the spinous processes and stand directly back of the patient and draw the flat surfaces of these two fingers over the spinous processes from the upper dorsal to the sacrum in such a manner that the spines of the vertebræ pass tightly between the two fingers, thus leaving a red streak where the cutaneous vessels press upon the spines of the vertebræ. In this manner slight deviations of the vertebræ laterally can be noted with the greatest accuracy by observing the red line. When a vertebra or a section of vertebræ are too posterior a heavy red streak is noticed and when a vertebra or vertebræ are anterior the streak is not so noticeable. Thus when suspicious points are noticed a special examination of the localized point can be given. This examination simply takes into consideration the contour and superficial condition of disordered portions of the spinal column. In a few cases such an examination will not be necessary, for the symptoms and signs of the disease will be so clearly manifested that one’s attention will be called directly to the cause. Still, great care should be taken in the majority of cases, as the osteopath finds causes of disease remote from the seat of complaint. We must always bear in mind the significance of reflex stimuli and sympathetic radiation.

In making a critical and exhaustive diagnosis of the spinal condition after the foregoing general examination has been made, it will be best to have the patient lie on the side upon the operating table. When the patient is in this position a more thorough examination can be made, as then the spinal muscles are not contracted unless abnormally so, for when a person is in the upright position muscles are continually contracting first on one side and then on the other, as one of their functions is to act as a support in keeping the spinal column erect. The patient lying on his side, the physician should then stand in front of him and reach over upon the back and make a thorough examination of the affected portions of the spinal column, chiefly through the dorsal and lumbar regions.

Consideration should be given the contraction of the muscles along the back, chiefly the deeper layers of muscles. It may even be necessary to relax some of the muscles before a thorough examination of the vertebræ can be made. From a pathological point of view too much stress should not be put upon the contracted state of the muscles; although in a number of instances the contracted muscles may be the primary cause of the patient’s trouble; especially so when the affection is due to atmospheric and other changes. Contraction of the muscles may be secondary to the lesions presented in the bony frame work. For instance, a dislocated vertebra may be the cause of an irritation to the innervation of certain muscles along the spinal column and thus cause them to

contract. Still, we must not lose sight of the importance of the contracted muscles from a diagnostic point of view. They are oftentimes prominent signs that a lesion exists in the immediate region and are thus faithful guides in locating the cause of diseases.

In closing the general consideration of the spinal column it is well to emphasize the importance of training the faculties to grasp at a glance the story told by the back as a region, instinctively placing the proper value on each physical sign and weaving them into a composite whole so that the patient's condition stands out a vivid picture on the osteopath's mind. When this is accomplished the more detailed observations are but incidental. Relative to the examination of the spinal column Clark[27] says: "To the osteopathic physician, the most important part of the human body is the spinal column. By its changes in contour and condition the various visceral diseases can be diagnosed, in most cases. I believe that every disease is characterized by extreme changes or signs, and I further believe that every chronic visceral disorder is manifest by changes in the spinal column that can be, by the practical eye and touch, readily interpreted. In short, there are various signs along the spinal column that point out the weakened or diseased parts of the body. This method of diagnosing disease, that is by noting these spinal changes, is distinctly osteopathic, and I believe the time will come when it will become such an exact science that the character of the spinal change or lesion is diagnostic not only of the viscus affected, but the way it is affected."

Regional examinations and diagnosis will now be taken up.

=Neck, Head and Face.=—To make a thorough diagnosis of the condition of the cervical vertebræ probably requires more skill and a more acute sense of touch than of any other region of the body. The irregularities and variations of the cervical vertebræ, the numerous muscles and the passage of many vessels through the neck are very liable to mislead one.

One may examine the cervical vertebræ by having the patient either lying down or in a sitting posture. The former position is preferable, as then the muscles of the neck are passive, and besides it is much easier to relax the muscles if such should be necessary. Also one has better control of the field of examination.

It is undoubtedly best for the student when learning to examine the cervical vertebræ to first examine along the base of the skull the condition of the occipital muscles (after the patient has assumed the dorsal position upon the treating table) for any contractions; for if disorder exists in the upper five cervical vertebræ the condition will be manifested by contraction of muscular fibres along the base of the occipital bone. The muscles of the occiput are supplied by fibres from the posterior branches of the upper five pairs of spinal nerves, and if lesions exist to these upper nerves a contracted state of more or less extent of the occipital muscles will occur, no matter how slight the lesion. Thus the examiner after locating contracted fibres under the occiput has a direct clue to lesions existing somewhere in the upper five cervical vertebræ. After locating these contracted fibres of the occipital region and then still keeping the finger upon the contracted muscular fibres and following them downward until the contractions are lost and seem to enter the spinal cord, one has then located the exact point of disorder that is causing the irritation to the muscular fibres involved, and most probably the cause of the affection from which the patient is suffering, i. e., provided one has reason to suspect the trouble is in the cervical vertebræ. Simply follow the contracted muscular fibre downward until it seems to enter the spinal cord and there one will find a lesion. After the osteopath has become expert in diagnosis this will not be necessary unless he has to make a very fine diagnosis or unless he is examining a stout neck where it is hard to examine through the heavy muscles. With this method one has a firm, flat, broad surface to work on (the occipital bone) making it very easy first to locate contracted muscles and second to trace the course of contracted muscles and thus find the disorder. Otherwise the beginner is apt to get confused by trying to examine the condition of the cervical vertebræ. Later, when a student becomes more expert such a procedure will rarely be necessary only in cases that require special work in the examination.

When the point of disorder has been located the diagnosis as to the exact character of the maladjustment has to be determined. The abnormal position of the vertebra, tenderness at the point involved, local contracted muscles, and limited motion are the four diagnostic points, although the temperature of the affected part as compared with the general cutaneous temperature and the state of the local vascular channels (blood and lymphatics) will occasionally be of aid.

Owing to the irregularity of the spinous processes of the cervical vertebræ in regard to their length, great care has to be taken in the examination. Probably there is no other region of the body that will tax the patience of the osteopathic student so much in his practical work as making a diagnosis of disorders in the cervical spine. It requires patient and persistent work to become a fair diagnostician of the cervical region, and it will take much experience to become expert in both the examination and treatment.

One can depend that lateral deviations of the spinous processes are abnormal in most instances. Placing the finger upon the spinous processes of two consecutive vertebras the student can readily tell whether or not there is any lateral displacement; but telling as to other features is impossible as the spinous processes vary greatly in length. When a vertebra is lateral, a slightly twisted condition will be felt by the finger when placed upon and between the two spinous processes.

To elicit the various degrees and combinations of rotation and sidebending one should depend upon the symmetry of the transverse processes. Reaching anterior to the sternocleidomastoid muscle, or better still, pushing the cleido muscles forward and reaching posterior to them upon the transverse processes, a very fair examination can then be given the vertebras. When the vertebras are deranged, especially anteriorly or posteriorly, that is the apposition of the articular facets, a slight elevation will be felt, possibly not any larger than a very small pea, either the anterior or posterior aspects of the transverse processes, depending upon which way the vertebræ are deranged. Remember that accompanying this slight elevation will be degrees of sensitiveness of the vertebra at the point deranged. In cases where the vertebra is lateral a slight eminence will be noted along the outside of the process. Commonly disordered vertebræ are not entirely deranged in one direction but are oftentimes slightly rotated, so we may find them dislocated antero-laterally or in various combinations of sidebending-rotation. Several consecutive vertebras may be deranged in like manner of direction; this condition is chiefly found in pathological curves of the spinal column. Probably the most common general lesion is a strained condition of several consecutive vertebræ, each one being nearly intact but all of them as a whole somewhat strained or twisted. Thus there are many pathological states to take into consideration, although it is not surprising to the osteopath when he realizes that many of our pains and aches are due to anatomical derangement. Frequently bending the head strongly forward and downward, or downward pressure with slight rotation will produce pain at the point of lesion.

Subdislocations of the =atlas= are probably among the most common lesions presented to the osteopath. Owing to the articulation of the atlas and occipital bone being an anatomically weak point and the neck muscles being exposed constantly to atmospheric changes, besides the articulation between the head and neck receiving the brunt of many jars, falls and strains, the atlas is especially susceptible to derangements. On account of the intimate relation of the atlas to the superior cervical ganglion of the sympathetic and to the vertebral blood vessels it is certainly very necessary that the atlas should be well taken care of. No other tissue maintains such a significant position in relation to the blood and nerve supply to and from the brain. To diagnose correctly the position of an atlas and to be able to correct it is undoubtedly one of the most essential achievements of the practitioner of osteopathy.

The most common disorders of the atlas are anterior and lateral displacements. Next in order come “rotary” lesions of the atlas, i. e., where the atlas has been deranged diagonally or simply twisted. It may also be luxated anteriorly and laterally, or posteriorly and laterally, etc. A posterior derangement of the atlas is comparatively a rare disorder, although owing to the many lesions that are found in atlases one has, during the course of a year’s practice, several to correct. The atlas may occasionally be slightly tipped laterally, anteriorly, or posteriorly, and in a few cases it may be somewhat impacted against the occipital bone. Many times when the atlas is displaced the axis is also deranged on account of the close relation between the atlas and axis by the odontoid process of the axis.

To examine the atlas the patient may be either in the sitting or dorsal posture; it matters but little which position is taken. Possibly the dorsal position is better, as then the neck muscles are more relaxed and if necessary an examination of the cervical spine, below the atlas, can easily be made.

By placing the middle finger of either hand on the transverse processes of the atlas when the patient is in the sitting posture, or the thumbs on the transverse processes when the patient is in the dorsal posture and comparing the two sides, undue prominence of one side or the other can easily be noted. Remember the transverse processes of the atlas are slightly above and posterior to the angle of the inferior maxilla. Always, in examining one side of the patient, compare it with the other; it may save considerable embarrassment. One side may seem abnormal when by comparing it with the other side, both sides may be found the same and still be normal. With the fingers still on the transverse processes note the distance between the process and angle of the jaw, besides take into consideration the tenderness of the locality, and, also, what is of essential importance in all interosseous lesions, its articular range of movements. There should be room enough (approximately) to just comfortably wedge the end of a medium sized middle finger between the transverse process of the atlas and the angle of the inferior maxilla when both are normal. Thus with the fingers on the transverse processes an expert will be able to readily determine whether or not an atlas is lateral or anterior. If an atlas is posterior the distance between the angles of the jaw and the transverse process will be increased, besides the atlas will be quite prominent posteriorly. In conjunction with the abnormality of the tissues (prominence or depression of the bone and state of the muscles) the sensitiveness of the locality is extremely significant.

Outside of displacements of the atlas, a lesion between the =axis= and =third cervical= is most common; following next in frequency are lesions of the =skull= and =atlas=. By that is meant where all the cervical vertebræ are intact as far as their individual relation is concerned, but the skull is forward, backward or lateral upon the spinal column. This condition occurs quite frequently. To determine its condition the same methods are employed as in diagnosing a deranged atlas; for if the dislocations exist between the atlas and skull the same diagnostic points are presented as far as the skull is concerned as when the atlas, or atlas and axis, are dislocated from the occipital bone or from the axis or third cervical. Following the preceding examinations, additional examination will have to be made to see whether or not the atlas is intact with the vertebræ below. If the atlas is found to be intact with the vertebræ below and lesions are presented between the atlas and the skull, then the disorder must be between the atlas and the skull and nowhere else. Occasionally there are cases where the skull is so far posterior upon the spinal column that the angles of the jaw strike against the transverse processes of the atlas when the jaw is opened widely.

Derangement of the =muscles= of the anterior and lateral regions of the =neck= are common. Especially are contractions of the muscles on either side of the larynx liable to occur. In examining the cervical region do not pay too much attention to the superficial muscles, but examine carefully the deeper muscles. It is from these that impingements of nerves and constrictions of vessels are likely to take place in the contracted fibres. Also, imbalance of muscular tension may be the source of the resulting malalignment. In examining for contracted muscles do not gouge into the muscle nor grasp the muscle roughly, but bear down lightly (inhibitory) upon the muscles and then gradually exert firmer pressure. By carefully and firmly exerting pressure over muscular areas the deep muscles can then be felt beneath the superficial ones. Otherwise when the muscles are manipulated severely the superficial ones will contract to such an extent that the deeper ones cannot be felt. The muscles contracting on either side of the larynx tend to draw the larynx downward and thus there may arise a source of irritation. The various muscles contracting in the antero-lateral region of the neck are very often the source of chronic irritations of the pharynx or throat. The omo-hyoid muscle may become contracted and cause slight traction on the hyoid bone and thus produce an irritating cough. To examine the muscles of the neck thoroughly it is best to have the patient flat upon the back, for then all the normal muscles are relaxed.

Lesions quite frequently occur in the =temporo-inferior maxillary= articulation. The lesion may be either unilateral or bilateral, more commonly the former. The disorder usually consists of a relaxation of the muscles and ligaments about the articulation which allows a slight but perceptible dropping of the inferior maxilla on the side involved. In other cases there may be presented a spasticity of tissue, while in still others some degree of joint infection may be found. Lesions of this articulation particularly impinge upon fibres of the fifth cranial nerve. The points of diagnosis are clicking and tenderness at the articulation. These two points are the symptoms of which the patient complains; those noticed by the osteopath are a slight deviation of the jaw to one side or the other when the jaw is opened and a flinching of the patient due to tenderness when pressure is exerted over the articulation of the jaw. When the physician places his fingers around the jaw, anterior to the angles, and the thumbs over the bridge of the nose, having patient open the mouth, at the same time exerting pressure with the fingers and thumb, a sharp click may be elicited by the return of the jaw into its articulation.

In disease of the =scalp= the condition of the muscles of the scalp should be taken into consideration. The muscles are usually found contracted. The contraction of the muscles is generally due, as well as the disease of the scalp, to derangement existing in the posterior branches of the upper five pairs of the cervical spinal nerves.

In the =neck=, anteriorly the =hyoid= is the only bone to consider. It is easily palpated by standing at the head of the table and with the second finger of each hand outline both ends to ascertain its relation with the thyroid cartilage. Note carefully any contracted tissue or glandular enlargements which might cause undue tension. The tilting of either end of the hyoid from these contractions is productive of much throat irritation. At the same time the =larynx= may be examined. It may be prolapsed, causing irritation of the laryngeal group of nerves. The =thyroid= and =cervical= glands should be palpated for enlargements, and all the muscles and ligaments for contractions. Externally the =tonsil= may be felt by deep pressure in front of the angle of the inferior maxilla.

=The Ribs.=—Under the osteopathic diagnosis of the ribs will be included the examination of the clavicle and sternum. To be able to diagnose intelligently, the position of the ribs in detail is very necessary to the osteopath. Many of the diseases of the heart and lungs, besides a large number of the diseases of the digestive tract, may be traced to a deranged rib; also, occasionally diseases of different regions of the head and neck may be due to dislocated ribs. In making a thorough examination of the ribs each rib should be carefully noted as to its position. The ribs may be examined when the patient is sitting up; but it is better to have the patient flat upon the back and especially so if the floating ribs are to be carefully examined, because the muscular tissues of the side if contracted will interfere with the diagnosis. In many instances the rib lesion is secondary to a vertebral subluxation.

An expert osteopathic diagnostician will be able to detect at once by a single passage of the hands down over the ribs if there are any disorders of them. In passing the flat of the hand, especially the flat part of the fingers over the ribs, carefully observe if the intercostal spaces are too narrow or too wide, and if any of the ribs are unduly prominent or depressed. If an intercostal space is too narrow it shows that the ribs on either side of the intercostal space are too close together. Then the question arises, which one of the ribs is crowding upon the intercostal space, or whether both of the ribs are crowded together. Usually when the sternal end of the rib is displaced upward, the involved rib is prominent and when displaced downward the rib is depressed. Thus it is commonly easy to diagnose which is the involved rib. Besides finding an abnormal position of the rib there will be more or less tenderness over the rib. Finding a rib prominent or depressed and tender is generally quite conclusive that the rib is displaced. Then the range of movement as expressed through the sense of resistance is a helpful guide in diagnosis.

If a =typical rib= is placed upon a flat surface and one end of it is depressed the other end will be elevated and _vice versa_. This peculiarity holds true as well when the ribs (typical) are dislocated in the living body. If the anterior end is elevated the posterior end is commonly depressed and _vice versa_. Care should be taken in examining the first rib and the false ribs, for in these ribs this peculiarity is not found.

As a whole a very complete diagnosis can be made of the condition of the ribs by examining the anterior part of the thorax, although it is always best to examine along the angles of the ribs if for nothing more than to confirm the diagnosis made at the sternal ends. Still it must be remembered that the preceding only holds good when the entire rib is dislocated. Many times simply one end of the rib is deranged and the other end is practically intact.

Besides careful examination of the sternal end of the rib, attention should be paid to the condition of the costal cartilages. The costal cartilages may become deranged at either the articulation with the rib or with the sternum. The same rule holds good when the costal cartilages are dislocated as when the ribs are dislocated, i. e., when the cartilages are prominent, they are usually displaced upward and when depressed the cartilage is displaced downward toward its neighbor.

One is apt to think that a rib is only dislocated at its vertebral end. Although lesions of the vertebral end are generally of greater significance as far as the etiological factors are concerned, still the sternal end of the rib must not be overlooked. In examining the vertebral end of a rib attention should be paid the angles of the ribs, for at the angles a better opportunity for examination is given on account of the prominence. It will be necessary in many cases to find out whether or not the vertebral end of the rib is lying between the transverse processes instead of in front of them. In many severe lesions of the ribs the vertebral end of the rib is dislocated upward or downward from the transverse process of the vertebra and lies between the transverse processes of the vertebræ above and below its attachment. This certainly requires considerable skill in the diagnosis, for oftentimes the point to be found is barely an eighth of an inch in diameter. It is usually best before making such a close examination to relax the tissues well over the field of examination.

The =ribs= as a whole may be too transverse or too oblique upon one side. This is chiefly found in pathological curves of the spine, but still such conditions may exist where there are severely contracted muscles, especially in some cases of paralysis. Thus the contour of the ribs must be taken into consideration by comparing one side with the other.

In examining the =first rib= an examination somewhat different from the other ribs should be given. It is best to have the patient assume a sitting posture; then place the middle fingers of each hand upon the first ribs near their centers and compare one with the other. Also note the difference of the spaces between the ribs and clavicles. Generally the first rib is dislocated upward, rarely downward. Besides finding an abnormal prominence or depression of the rib at its center considerable tenderness will be noticed. Examinations of this region are every day experiences with the osteopath.

When diagnosing the position of the =floating ribs= it is best to have the patient lie flat upon the back with the thighs flexed upon the abdomen, so that the tissues about the lower ribs may be entirely relaxed. Then by placing the flat of the fingers carefully over the ribs the outline and position of them can be easily discerned. The floating ribs are oftentimes found deranged and are the source of a great deal of suffering through the iliac regions. These ribs may become dislocated from the vertebral ends and drop down obliquely toward the iliac crest, or else the free end may become locked beneath the rib above. Occasionally both ends of the rib drop down quite perceptibly and consequently is the cause of considerable distress. In such instances the rib is depressed inward so that the normal contour of the lower thorax is lost.

An examination of the =clavicle= should be carefully made. Always compare the clavicle with its fellow and examine thoroughly its articulation with the sternum as well as at the acromial prominence. Often the sternal end of the clavicle is slightly dislocated

posteriorly to the sternum; although it may become completely luxated. The acromial end may be dislocated upward or downward.

In examining the =sternum= special attention should be given the articulation of the manubrium and gladiolus. This is due to the crowding anteriorly of the articulation of the sternal parts. Normally until well along in adult life there should be some movement here due to its membranous attachment. Occasionally the ensiform cartilage is turned inward, producing a tender point, but this rarely occurs. Also the articulation of the cartilages in the region of the eighth, ninth, and tenth ribs may be found considerably deranged, causing local tenderness and even stomach trouble.

=Dorsal= and =Lumbar Spinal Region=.—With the patient sitting on the table abnormal deviations can be readily noted. There may be lateral swerves, from muscular weakness, or unilateral tension, involving the whole spine or less, or a reversal of natural curves, i. e., the spine depressed anteriorly between the shoulders and posteriorly in the lumbar making the straight spine. There may be, also, an exaggerated normal curve in the dorsal region producing a kyphosis with a compensatory lordosis in the lumbar region sufficiently great to change its relations with the pelvis. By the method previously given, now outline the spinal column for lateral and bilateral scoliosis. These, frequently, are at their incipiency, and to the casual observer would pass unnoticed. It is well to make an outline of the spine before beginning treatment, and at times following, that progress may be observed. A simple method is lead tape which can be had from any plumber shop and can be molded to the deformity and traced on paper together with date of examination. H. F. Goetz has perfected an appliance for outlining and recording these deviations. Observe well the ligaments, as well as extent of joint movement, under deep palpation; from irritation they may become thickened and more or less fill the spaces about the spines and transverse processes, causing a rigid, smooth spine.

To make a detailed examination the patient should be stretched out on one side upon a treating table, although the general examination may be sufficient. Then, standing in front of the patient and reaching over him, a most careful diagnosis can be made. Do not stand back of the patient as the flat of the fingers can not be used to advantage in outlining the different vertebræ. The various contracted muscles that may be found along the spinal column will be of valuable aid in locating derangements of the vertebræ and vertebral ends of the ribs. By using contracted muscles along the spinal column as a guide for locating lesions, reference to the large superficial muscles is not made, but to the small areas of contracted fibres of the deep muscles. It is the deep muscles that become more or less contracted, and even fibrotic, when lesions of the vertebræ and ribs exist. The superficial muscles are generally contracted by atmospheric changes, slumped postures, wrong habits, etc., and are not generally the result of disorders in the osseous system. The preceding points in regard to contracted muscles cannot be too carefully observed for there is a tendency among many osteopaths to treat the contracted deep muscles as primary lesions in nearly every case. Remember that if they are not due to the motor nerve fibres of the muscles being irritated by the spinal lesion, or to a reflex stimulus, or to a compensatory change, that although the muscular tension may be the inception of the almost certain interosseous lesion, still the leverages secured through bony adjusting are very essential not only in correcting the osseous malposition but in loosening and releasing fibrous muscles and thickened ligaments.

=Thorax.=—Examination of the thorax as a region has been largely gone over in speaking of the ribs and their sternal attachment, cartilages, sternum and the clavicles, but its appearance as a whole should be carefully noted for it will be a valuable aid in diagnosis. Deviations from the normal, such as the emphysematous or barrel-shaped chest in asthmatic affections, or chronic cough, or accompanying kyphosis, the flat chest and its association with phthisis, the rachitic, etc., should be considered. Spinal deformities are reflected in the thorax by marked changes in contour, such as elevations and depressions corresponding to the spinal changes. These result in marked interference with the thoracic organs and in young subjects are of particular interest. Rib changes are frequently the result of vertebral deviations.

=Abdomen.=—The position for examination of the abdominal viscera is usually with the patient supine, head slightly elevated, knees drawn up partially and supported to relieve any muscular strain, and with the hands at the sides. In this position complete relaxation is obtained. Observe any enlargements from gas, fluid, or tumor, muscular changes, color, etc. The patient may, also, be placed upon the side, and in the knee-chest position for further verification of the diagnosis. Where the abdominal wall is much relaxed, or there is a pendulous abdomen with enteroptosis, there will be found a change of relations of the viscera by these different positions, allowing them to be palpated in another position. When there is marked tenderness it is often possible to go deeper with less discomfort with the patient in the knee-chest position. The Trendelenburg position may also be utilized. Where ascites is suspected palpation should be made with the patient in various positions in order to note changes of location of the fluid. Frequently much can be learned by inspection with the patient standing. Clues to visceral disturbance can often be had by tracing the nerve connection from the spinal lesions to the suspected part.

In examining the =liver= care must be taken that any gouging or severe bruising of the organ does not take place. The liver can be outlined by percussion and also by palpation of its lower and inner borders Congestions, atrophy, enlargement or hardening should be noted, also any change in position.

A rather complete examination can be given the =biliary tract= from the =gall-bladder= to the =duodenal orifice= of the =biliary duct=. By a careful inhibitory pressure over the duct the outline of the tract can be discerned providing the patient is not too stout. When the tract is swollen considerable tenderness will be present. The patient will complain of a stabbing or piercing pain upon pressure and manipulation if the duct is inflamed.

Usually the tenderness is greatest nearer the =duodenal orifice=. The duodenal orifice is about one and one-half inches diagonally downward to the right from the umbilicus. In cases of impacted =gall-stones= the osteopath as a rule has very little trouble in locating the stone.

The =spleen= may be percussed and when in a markedly enlarged condition its lower border can be palpated. Great care must be used in the latter condition as there is danger of rupture.

In examining the =stomach= the usual methods of inspection, palpation, percussion, analysis of the contents, etc., are employed.

Palpation and manipulation over the =intestines= are practiced a great deal by the osteopath in various intestinal diseases. By his educated sense of touch he is usually able to locate at once any =impactions= of =fecal matter=. Such impactions are generally found in the ilio-cecal and sigmoid regions. In the various acute =obstructions= from invagination, tumors, twists, adhesions, spasticity, knots, etc., many times one is able to readily locate the seat of the disturbance. There is one point to specially emphasize; that is, do not overlook prolapsed regions of the intestines; such occur frequently and are a source of considerable distress, especially constipation. Simple manipulation will never do much good, neither will spinal treatment or injections, as a rule. A specific treatment must be given and, that is, after locating the exact point of prolapse, to reach carefully beneath the fold and replace it.

In emaciated subjects the =kidneys= can be readily located, and in a few instances when they are diseased one can feel the contracted tissues about them. Be very careful not to injure the =capsule= about the kidney. Do not punch or gouge them in the least; but locate the kidneys by a careful inhibitory palpation.

=Lumbar and Pelvis.=—The intimate relation between the lumbar spine and pelvis make a consideration of them as a region necessary. Outside of ordinary curvatures involving both the dorsal and lumbar regions there are certain conditions which involve but one structure and require careful differential diagnosis to determine whether the lumbar or pelvis is at fault. In the former the fifth vertebra is a weak point and is most frequently at fault. The deviations are usually a sidebending and frequently accompanied with some rotation. Occasionally a malstructure of the lower lumbar or pathologically relaxed ligaments will approximate the spines and be misleading as to the real condition. A rotation or lateral tilting of the fifth lumbar may have the effect of elevating the crest of the ilium so that the innominatum would appear involved. There will be a difference in the length of the legs, angles of feet when patient is lying on the back, anterior spines out of line and tenderness of the muscles attached near them. However, other diagnostic points of innominate lesions, i. e., tenderness of symphysis and sacro-iliac articulation, and prominence of the posterior spine, will be lacking. Marked deviation of other lumbar vertebræ may produce practically the same effect, but the lesion will be so apparent that there will be no doubt as to the cause.

To be able to diagnose accurately and intelligently the pelvic region requires nearly as much skill as in examining the cervical region. The pelvic bones are liable to many subdislocations, especially in the female. However, it should be remembered that many apparent innominate lesions are secondary or compensatory changes due to lumbar lesions. The pelvis as a whole may be tipped anteriorly or posteriorly upon the spinal column. It also may be twisted or rotated laterally upon the spinal column. The most common lesions are subluxations of an innominatum forward, backward, upward, or downward, or various combinations of these displacements, such as a tipping forward and downward of an innominatum, or a tipping backward and upward, but these combinations do not always exist in the manner given. As a rule when the ilium is anterior, the ischium posterior, then the innominatum as a whole is downward; when the ilium is posterior, the ischium anterior, then the innominatum as a whole is upward. This is only a rule, there are exceptions to it; for in some few cases when the ilium is anterior, the ischium posterior, the innominatum may be higher, and when the ilium is posterior and the ischium anterior the innominatum may be lower.

To be able to diagnose such derangements will require skill and practice; still there are symptoms and signs that are characteristic of such disorders. In examining the pelvic bones have the patient flat upon the back at first. Be sure he is flat upon the back for a very slight variation may make considerable difference in the relation of the pelvic bones, one to the other, so far as the diagnostic points are concerned. Then go to the feet of the patient and grasp the ankles firmly, rotate laterally both legs, first to one side and then to the other, as well as pull and push both limbs slightly, and then bring the heels together directly in the median fine of the body and compare the length of the limbs at the heels. If there is any disorder whatever in one innominatum, and the thigh muscles have been relaxed thoroughly by the preceding movements and the heels are brought together in the median line of the body, a difference in the length of the limbs will readily be observed at the inner malleoli or the heels. For if the ilium is forward the ischium must be backward and as a rule the innominatum is thrown downward, thus causing an apparent lengthening of the limb which will be noticed by comparing the heels; if the ilium is backward the ischium must be forward and as a rule the innominatum is then upward, causing an apparent shortening of the limb on the affected side. A very slight variation in the pelvis will make considerable difference in an apparent lengthening or shortening of the limbs. Such conditions are generally met with several times a day by osteopaths. The object of the lateral rotary movement and the pushing and pulling of the limbs is to make sure that all the thigh muscles are thoroughly relaxed, for it is a very easy matter for contracted muscles in one thigh to produce an apparent shortening of the limb. Also be very careful in comparing the length of the two limbs at the heels where they come together that they are exactly in the median line of the body, for if they should be to one side or the other, however slightly, there would be an apparent lengthening of the outer limb as compared with the limb near the median line. While the patient remains flat upon the back it is a good plan to compare the anterior spines of the ilia. It may be readily noticed that one is higher or more depressed than the other, which will help to confirm the diagnosis. It is a good plan also to have the patient sit up squarely upon the table and compare the crests and posterior spines of the ilia; thus one may be seen to be higher than the other. Then, also, note the angles of the feet when patient is supine; an everted foot usually means that the limb is shorter due to the tilted pelvis; the opposite is commonly true when the foot is inverted. However, this is not an absolute rule. Care should be taken in differential diagnosis of possible old fracture of leg, of infantile paralysis, of asymmetry, etc.

There are =three diagnostic points= exclusive of all other signs that are quite conclusive when coupled with the preceding examination. If an innominatum is dislocated or subdislocated there will be tenderness over the symphysis pubis on the side affected, tenderness over the ilio-sacral articulation on the side affected, and tenderness along the crest of ilium where the abdominal muscles are attached. When tenderness is found at these three points it is quite conclusive that the innominatum is deranged, for at the symphysis pubis and ilio-sacral articulation tenderness must exist if the innominatum is disturbed, and by a change in the crest of the ilium the abdominal parietes will be affected, provided they are not too much debilitated. Marked tenderness of the external cutaneous nerve as it passes over the crest of the ilium below the anterior spine will be noticed on the unaffected side (Dr. Still). There will be, on rectal examination, marked tension of the tissues on the affected side. Possibly the patient may complain of pain exclusively in one side along the pelvis and limb which will be a leading symptom telling which side is affected.

=Additional diagnostic= signs will be rigidity of muscles along the ilio-sacral articulation and abnormal prominence or depression of the ilium at its articulation with the sacrum, depending upon which way the innominatum has slipped. Considerable deviation of the pubic bones may be noticed. The pubic bone on the side affected may be either thrown upward or downward.

Radiographs have repeatedly revealed subluxations of the innominate bones in many instances. This is certainly quite conclusive in confirmation of the osteopathic ideas in regard to the pelvic bones becoming dislocated.

=Sacrum.=—Examination of the sacrum is best made with the patient lying on the side, with the osteopath standing in front and with the hand palpate its posterior surface. In the sitting posture its relation with both innominates can be determined. It is displaced posteriorly but seldom, the most frequent being anterior, downward, and a combination of the two. In the anterior conditions tenderness at the sacro-iliac articulations is a good point, but it must not be confounded with an innominate lesion. The downward displacement is shown by comparison with the lower lumbar vertebræ. Observe the relation between the two, as a change in contour of the spine will also change the angle of the sacrum and _vice versa_.

=Coccyx.=—With the patient and operator in same position as for the sacral examination outline the coccyx, as to first, =contour=; second, =rigidity=; third, =sensitiveness=. If abnormalities are detected go to the other side of the table and with a well lubricated index finger palpate its anterior surface. Changed contour, displacements, and old fractures can be readily determined. The most common deviation is anterior at its union with the sacrum. The lateral form generally resulting from muscular contraction is next, with posterior but seldom. “If the lower part of the sacrum is rotated backward, the sacro-coccygeal articulation or angle is affected

or becomes more acute, since the tip of the coccyx is not displaced, but held in position by structures attached to it. If the sacrum is displaced downward the effect is about the same. Often this sort of sacral lesion is mistaken for an anterior luxation of the coccyx."[28] Remember that normally there should be some movement of the coccyx. It has a fibro-membranous articulation.

=Uterine=, =ovarian= and =rectal= examinations are largely of the same nature as those given by other practitioners, although osteopaths find that oftentimes other practitioners are mistaken in regard to the etiology of many diseases to which these organs are subject.

=Arms= and =Legs=.—There is comparatively little that is exclusively osteopathic in regard to the diagnosis of disorders of the arms and legs. One important feature that the osteopath finds in examining the arms and legs is that many of the disorders supposed to originate in the affected member are found to be caused from vertebral or rib dislocations. Innominate and lumbar lesions are particularly fruitful sources of trouble in the legs and feet. Always carefully examine the spine in the region of innervation to the arms and legs when they are affected. The shoulder and hip joints, as well as all joints, are subject to partial dislocations. Many times when pain or other symptoms are presented in the arms or legs the trouble is at the shoulder or hip joint or in the spinal column. There are two regions that are very apt to be overlooked in the examinations of the arms and legs and they are the elbow joint and the fibula. The small bones of the =ankle= and =wrist= as well as of the foot and hand are subject to many dislocations which are easily discerned upon examination and often overlooked. Special emphasis should be given in regard to many supposed diseases of the knee joints which are really caused by lesions in the spine or at the hip joint.

Osteopathic Prognosis

Everyone is of the opinion that to forecast the probable result of a disease is one of the most difficult problems the physician has to meet. To state the duration, course, and termination of an attack of disease as presented by its nature and symptoms implies an accurate knowledge of both disease processes and changes, and an insight into the individual's idiosyncrasies backed by ripe clinical experience. And after each of these factors has been carefully considered to balance one against the other, nothing short of superhuman knowledge may present a sufficient insight in order to render an accurate prognosis. A prognosis represents the culmination of one's learning, an understanding of disease characteristics, and an insight into temperament.

C. M. T. Hulett[29] says: "Only when we can know all the conditions, causative and sequential, with their possible complications and terminations, together with a full history of therapeutic results in a large number of similar cases, and carefully analyzing and weighing these various elements, are we prepared to really make a prognosis." Nettie H. Bolles[30] writes as follows: "The prognosis depends upon the cause of the disease, the possibility of removing the cause, or the likelihood of recurrence of causes, and the chances of avoiding such recurrence. The circumstances to modify the outlook are various and deserve careful consideration." It is not the purpose here to go into the many essential details, for that would mean an outline and forecast of all disease processes, and the effect of numerous extenuating circumstances. The medical profession have been gathering data for these three thousand years and prognosis with them is still inaccurate and incomplete. Osteopathic science will add just so much to the accuracy of prognosis as the sum total of the knowledge displayed in the fields of osteopathic etiology, diagnosis, pathology and therapeutics. Suffice it to give here a few salient practical hints as noted in the osteopathic treating room and at the bedside.

Osteopathically it may be said that prognosis depends, first, upon the true conception of osteopathy; second, upon the relative value of all factors pertaining to health and disease; and, third, upon the skill (technique and native ability) of the osteopath. The first and second being granted, the third includes a remarkably practical and pregnant field, for in no school does the physician get into as close touch and understanding of the actual condition of the patient's disorder as in the osteopathic. Although the fundamentals and principles of the osteopathic conception of diseases are really broad, liberal, and all-inclusive, still owing to the fact that each individual (and thus each disease) is more or less a law unto himself should there not be absolute tables and prescriptions to be governed by; remember, however, this does not imply our fundamentals are not basic or our principles are not truths, but rather the application and execution of the same are as varied as the individual's constitution, temperament, and disease. Herein rests the really difficult practical consideration of etiology, pathology, diagnosis, treatment, and prognosis. In other words, if the diagnosis and treatment are accurate the result rests entirely with the patient.

First, too much emphasis cannot be placed upon the fact that prognosis is dependent upon the osteopath—his education, training, ability, experience, and technique. One's fitness is most important. And fitness and personality complement each other. An osteopath may know theory and still not be practical; still one cannot be practical unless he knows theory.

Second, osteopathic treatment frequently changes the usual course of acute disease. It is well known that many diseases have a certain regular course in their history. Many times the osteopath will be able to abort, lessen the severity, or cut short the ailment, thus changing the recognized symptoms and termination.

Third, the knack of treatment, or knowing how to treat, not only one region of the body but all regions, not only one temperament but all temperaments.

Fourth, the preparatory treatment before correcting the lesion. Prevention, palliation, or cure, and thus prognosis, may be dependent upon a necessary preparatory treatment. Here is where a study of the patient's temperament is very essential.

Fifth, a prolonged treatment may defeat one's purpose. As a rule a comparatively short, thoroughly indicated, specific treatment is best.

Sixth, much, relative to prognosis, can be told by the tone of the vertebral ligaments. When a lesion corrects too easily or does not remain well in place it shows a lack of tonicity on the part of the ligaments and muscles. Improvement is in direct ration to the increase of tonicity.

Seventh, special care should be taken with the irritable spine. This spine commonly precedes the debilitated spine. Unless precaution is taken to apply inhibition before treating specifically a cure may be prevented or at least the disorder prolonged.

Eighth, relaxation of muscles is not always essential, although the lack of it may prevent the correction of primary lesions. The relaxation should be carried out with care in order that all shock and irritation may be kept at a minimum.

Ninth, needless stretching, traction, extending, rotation, and snapping of the neck is not only useless but may be positively dangerous. Rarely is it necessary to go through the above "movements" as many are accustomed to do.

Tenth, it may be necessary, but not always, to give as additional treatment, after the anatomical defect has been specifically treated, a certain amount of stretching and moulding of the parts.

Eleventh, owing to the close personal relations of physician and patient, personality has a powerful influence on prognosis.

Twelfth, too much emphasis cannot be placed upon the uselessness and injurious effects of over and misapplied treatment.

All of the above have a positive bearing on prognosis. The osteopath should study his technique well. He will find that it gradually changes and improves from year to year. In a word, as he gains in experience he will become more skillful by giving careful attention to the development of the sense of touch, by noting the resistance of the tissues, and a score of details that are very hard to describe but the sum total of which determines and indicates the successful osteopath.

Another practical point that bears upon prognosis as well as upon the health of the osteopath is the manner of giving treatment. First, the height of the treating table should correspond to the height of the practitioner. The table should be made for the practitioner and not the practitioner fitted and warped according to a certain table. Second, give part of the treatments on a treating stool. Here there is greater freedom of movement on the part of the patient, hence greater and more effective leverage can be obtained. Suit your treatment to the patient, not your patient to the treatment. Third, make your weight count for energy expended in the treatment. As soon as one set of muscles become tired substitute another set, e. g., the back muscles and the arms, the arms and the hands. Fourth, whenever possible substitute the weight of the patient for expended energy. Fifth, when lifting keep the spinal column straight; do the bending of the body at the knees. Hence a better treatment and a more favorable prognosis, and besides that new occupation neurosis, the "=osteopathic back=," will be materially lessened in both severity and frequency.

OSTEOPATHIC TECHNIQUE

The technique of treatment is, in a sense, a personal factor, for it is a well known fact no two osteopaths treat just alike. Nevertheless, the principles of technique are constant and universally applicable, and he who applies them with specificity manifestly secures the best results, and exhibits a technique that is finished and characteristically osteopathic. General manipulations are not essentially osteopathic, although by employing them a few definite results may be obtained; still such technique should not be classed as distinctive osteopathic therapy. Every case is a law unto itself and must be studied individually in order to be able to understand it perfectly. So much depends upon the ability of the osteopath in the treating of a case, that in order to meet the indications intelligently he must have command of the various anatomical details of the body, not only in his mind but upon his finger tips.[31]

The =sense of touch= should be very acutely developed and this requires months of persistent, practical experience. A carefully educated sense of touch is the keynote to both osteopathic diagnosis and operative technique. From the very nature of the osteopathic conception—the physical body viewed as a mechanism whose disordered or diseased conditions demand anatomical readjustment—it is imperative that a delicate and educated sense of touch be acquired in order to logically and successfully apply its tenets. Proficiency means not only being able to note certain small physical irregularities, and various degrees and areas of muscular contractions, and variations in body temperature, but the extent and state of vital resistance, that is, tissue condition, and the feeling of organic resistance, e. g., the heart, lungs, liver. These are the special features wherein osteopathic fingers detect disease causes and traces. To know the difference between normal and abnormal structural deviations and distortions, as well as organic changes, requires an accurate, detailed knowledge of anatomy and pathology with a systematic daily education of the sense of touch; but to realize, appreciate and know by tissue resistance feeling that nutritional condition is improving requires much more practical experience.

Thus two very practical points should be taught to and thoroughly impressed upon every osteopathic student: First, =the sense of resistance of the tissues=. This gives us an absolute clue to the vitality of the patient. As has been stated, there is a vast difference between the feel, the sense of resistance, of normal and abnormal tissues; for instance, a normal muscle and a contractured muscle, a normal liver and a congested liver, a normal intestine and a prolapsed intestine and these differences comprise innumerable gradations.

Second, =the receptivity of the patient to treatment=. This is dependent upon the vitality of the tissues. The sense of resistance to touch gives us an important diagnostic clue; the receptivity of the patient to treatment tells us much as to prognosis. After a few treatments the receptiveness will be positive or negative; that is, the patient is, or is not, responding to treatment. Consequently the receptivity of the patient usually tells much as to the state of nutrition.

Definite principles should be followed when applying the technique, for the osteopathic lesion is a “structural perversion,” thus indicating mechanical readjustment for its correction. The time is coming when the technique will be taught graphically and mathematically. This would not be a difficult thing to do, and it could not but prove invaluable aid to the student. He can then the more readily and comprehensively grasp the principles involved. To resolve and illustrate manipulative readjustment to and by the principles of mechanics would add considerable to osteopathic development. For example, how nicely the correction of certain innominata maladjustments illustrates the principle of the wheel and axle. Vertebral and rib displacements when readjusted make application of the principles of the simple machines. We are gradually approaching a more comprehensive understanding of the physiologic movements of the spine and of the etiologic role of muscle tension. This is part of the foundation work. Great care must be exercised in correlating this data with the individual case, for in therapy we are dealing with abnormalities—not alone normal physiologic changes. If our distinctive dynamics and therapeutics were taught in this manner the average osteopath would be more specific and comprehensive in his work and as a consequence more scientific. And consequently the principles involved in each and every case would stand out clearly. Hence diagnosis would be more exact, routine pommeling discarded, and better all around technique executed.

Two general rules are applicable to all dislocations, whether partial or complete: 1. Exaggerate or increase the dislocation. This is to relax the tissues about the dislocated articulation and to disengage the articular points that have become locked. 2. Reduce the dislocation by retracing the path along which the parts were dislocated. Hence to =correct= a =lesion=, for example, a vertebral lesion: (1) Exaggerate the lesion. (2) Place the fingers of the hand that are not employed in exaggerating the lesion over the extended portion of the lesion. (3) Extend the region that is flexed when the lesion was exaggerated. (4) When the lesion is being extended produce traction and slight rotation of the region. (5) At the same time extension, traction and rotation is being produced

push in upon the extended portion of the lesion. To this might be added for sake of clearness and greater assurance of success: (a) Be positive the focal point absolutely corresponds to the lesion, or else most if not all of your effort will be useless. (b) Just before reaching the maximum of exaggeration have your fingers correctly placed for the readjustment, and at the very moment of maximum exaggeration or just a fraction of a second prior begin to correct or readjust, or else you will lose the vantage gained and the operation will probably be a failure. (c) The general traction and rotation are to aid in unlocking the lesion, not to readjust as some may think. Inhibiting and releasing the soft tissues, such as spasms, contractions and contractures of muscles, and stretching thickened and adherent ligaments is very important preliminary work. Then, next to securing exact leverages an essential point is to maintain the release or exaggeration until the readjusting step is incepted. In other words, coordination of all factors is the desideratum. The lack of this is the cause of many failures. Hot fomentations frequently assist in relaxing irritable and spastic soft tissues. This, however, is but a preliminary measure. All rough handling, needless snapping of parts, and excessive rotation and stretching are not only apt to tighten the lesion more, shock the system and irritate the parts, but it may be absolutely dangerous.

It should not be forgotten that the osteopath includes many measures in his treatment of various diseases, as nursing, dieting, hygiene, sanitation, hydrotherapy, antidotes, antiseptics, etc., and does not depend upon readjustive manipulation alone, although correcting disordered anatomical structures and perversions are paramount in the treatment.

=The General Treatment.=—A general treatment but accentuates the ignorance, in a majority of cases, of many so-termed osteopaths. It is a deplorable fact that there is a tendency among some osteopaths to give general treatments in every case presented. The only explanation of such a procedure that one can think of is a lack of conception as to what osteopathy really is. To give a general treatment in every case is not only actually detrimental to the patient but it is the height of folly on the osteopath's part, for it gets him into a slovenly habit of procedure from both scientific and curative points of view, besides giving the outside world an impression that osteopathy is but little different from massage and Swedish movements instead of skillful, mechanical engineering of the human body. But a "general treatment" is not to be confused with definite attention to be a series of more or less interrelated lesions. The essential point is to normalize the body when and where distinctly indicated and after a skillful manner.

A general treatment, broadly speaking, should be given only under three conditions: (1) Constitutional diseases that are to be treated symptomatically. (2) Certain anemic cases. (3) When one is ignorant of the real cause of the disease. Each of these conditions is self-evident why a general treatment should be given. A fourth might be added, for those individuals who think they are not getting value received unless they are treated from head to foot. Such patients are usually ignorant of the philosophy of osteopathy and it is the osteopath's duty to teach them differently.

The general treatment consists in stretching the spinal column from the atlas to the coccyx and relaxing all contracted muscles along both sides of the spinal column, besides giving special treatment to the cervical region, between the scapulæ, the splanchnics and internal and external rotation of the legs. It is no wonder that fake osteopaths do cure a case occasionally. They are quite certain to correct some disorder by pulling and hauling a patient around in such a manner. Still on the other hand they are very likely to do injury to the patient. Those who claim that no injury can come from osteopathic treatment are mistaken. One can injure a person by treatment if he is not careful. It does not stand to reason that the most delicately constructed mechanism should stand any amount of manipulation and misdirected force that may be given it.

=Positions of the Patient and Physician in Treating.=—The position of the patient when a treatment is given depends altogether upon the affection to be treated. Probably about one-half of the cases can be treated to advantage upon a table, the remainder sitting on a stool. Many osteopaths treat nearly all their patients upon a table. It is much better to change back and forth, because to correct a certain disorder may be hard upon the table, but will be comparatively easy when the patient is on a stool, and _vice versa_. Besides, constantly changing back and forth rests a physician greatly.

Learn to treat in various positions, because it will be impossible to have all cases assume a certain position when being treated; and especially in treating acute cases one is obliged to suit his treatment to the patient and not the patient to the treatment. There is also a tendency for one to get into slovenly habits of treating when patients are all placed practically in one position, and certainly one cannot treat all cases in one position to equal advantage. Also learn to treat as well with one hand as the other. Many times one will be in such positions that equal use of either hand will be required. Carefully educate the sense of touch in both hands.

Another point should receive consideration: learn to shift the strength exerted in treating from one set of muscles to others. For example, when one is standing for a long time he will continually shift his weight from one limb to the other. In the same manner in treating use the strength of the hands awhile, then the arms, then the muscles of the back, then the weight of the body, etc.; all in

such a manner that there is a constant change by utilizing certain groups of muscles for the same work, as well as utilizing the weight of the body of both physician and patient to advantage. It rests a physician greatly and thus allows him to perform a maximum amount of work with a minimum amount of strength and labor.

It is frequently an advantage to the physician to treat upon the nude skin, thus preventing the fingers from becoming tender. Gowns can be easily made that open down the back so that the patient does not have to disrobe.

=The Neck and Head.=—In the treatment of the neck the patient may assume the sitting posture or lie flat upon the back. The latter is preferable, as then one has complete control of the neck and head. Absolute control of a part is always necessary and when this is secured the dangers are reduced to a minimum, provided always that reasonable discretion as to the amount of strength, is used. Before correcting the various deviations of the cervical vertebræ it is usually best to thoroughly relax all the muscles, superficial and deep, about the field of operation. In relaxing muscles three methods may be employed. The muscle may be firmly grasped and manipulated until relaxed, or a firm pressure may be exerted upon the muscle and thus inhibit its nerve force until the muscle relaxes, or the muscle may be longitudinally stretched. The second method is comparatively slow and is usually given in acute cases where the patients are so weak and exhausted that they cannot stand any severe manipulation. This method, however, has certain advantages when employed as a preparatory step in interosseous adjustments, though steady traction accompanied with slight rotation, if precisely localized, has many advocates.

In relaxing muscles by manipulation, grasp firmly the belly of the muscle and draw outward on the muscle several times until it relaxes. If the patient is sitting, place one hand upon the head of the patient or about the chin in such a manner that complete control of the head is maintained throughout the procedure; then with the fingers of the other hand upon the contracted muscular fibres a manipulating or kneading of the muscle can be given. It is best to flex the neck and head to the side where the contracted muscles are, so that a better hold of the muscle may be maintained; then by a series of flexions and extensions with manipulation of the contracted muscles outward, results can be readily obtained. When the patient is lying on the back the physician may stand to one side of the patient's head and with one hand on the forehead of the patient and the other hand around the opposite side of the neck, a rotary motion of the head and neck, which is equal to flexion and extension in the sitting posture, may be given by the hand on the frontal region while the other hand relaxes the muscles; or the osteopath may stand at the head of the patient and with either hand on the side of the head and neck of the patient a series of rotary movements of the head and neck may be given with manipulation of first one side of the neck and then the other; the hands and fingers being placed in such a manner that when the fingers of one hand are relaxing the muscles on its side the other hand is executing the movements of the head and neck, each hand continually alternating in the work. This latter method requires some practice in order to do the work readily and successfully, for quite a variety of movements are required.

In the former method after one has worked on one side he is obliged to change to the other side and go through the same process. Movements may also be given to stretch the contracted muscles, thus overcoming the contraction and producing relaxation of the muscles.

After having relaxed the muscles over the field of operation, correcting the vertebræ will generally be easier to accomplish. In readjusting an atlas it matters but little whether the patient is sitting up or lying down. A firm hold of the atlas can be gotten in either instance. In correcting the middle and lower cervical vertebræ it is best to place the patient upon the back.

In correcting dislocations, as heretofore suggested, two general rules should be followed: (1) Exaggerate or increase the dislocation. This is to relax the tissues about the dislocated articulation and to disengage the articular points that have become locked. (2) Reduce the lesion by retracing the path along which the parts were dislocated. One can readily see that a dislocated ball and socket joint could be reduced only by the dislocated bone retracing the path by which it left its socket, for the capsular ligament would at once prevent its returning to the socket by any path other than that taken when dislocated. This applies to all dislocations to a greater or less extent.

After locating the exact position of the abnormal vertebra the first rule is applied, i. e., exaggerating the lesion by flexing the head in the opposite direction to which the vertebra is dislocated. Then with one or two fingers placed firmly upon the side of the vertebra in the direction dislocated, so that when the proper time comes the vertebra may be pushed or slightly rotated back into its normal position, with the other hand produce flexion of the neck, so that the angle of flexion is exactly over the involved vertebra; next produce slight traction, so as to be sure that the articular points will be disengaged; and then with rotation and extension of the head to a normal or upright posture, at the same time pushing in on the disordered vertebra, are the movements to be executed in

reducing a dislocated vertebra. It takes considerable practice to be able to correct a vertebra and to know when it is corrected. The amount of force applied varies greatly in different cases. Cases of recent subdislocation require but little force unless there is marked spasticity of tissue, while in long standing cases many times the amount of force required is about all that one wishes to exert. As a rule in many chronic cases it is better to give a series of preparatory treatments in order to reduce muscle fibrosis and thickening of capsular ligament. Remember that often it is a slight rotary movement or twist given that aids the most in executing rule second. No matter to what position a vertebra is rotated or side-bent the principles applied are the same in each case.

Be very careful when flexing, extending or rotating the neck that too much strain is not brought to bear upon the ligaments. Some osteopaths seem to take delight in rotating and flexing the neck to a great degree. It is a dangerous procedure and moreover does not accomplish anything in particular. It should be kept in mind that osteopathic treatment is scientific and not a number of general movements of various regions of the body. Locate the lesions exactly and then a specific treatment can be given in every instance. To illustrate the treatment according to the preceding rules we will assume that a certain cervical vertebra is anterior, say the fourth cervical. This means that there is an interosseous lesion between the fourth and fifth. The inferior articular processes and facets of the fourth have slipped upward and forward on the opposing facets of the fifth. First, hyperextend the head in such a manner that the fulcrum comes exactly over the displaced articulating planes, thus throwing the fourth vertebra still more anterior, or in other words, exaggerating the lesion or increasing the space anteriorly between the fourth and fifth cervicals, so that when the head is flexed forward and pressure is exerted upon the anterior part of the vertebra (body or transverse process) the vertebra will have room and release enough to occupy its normal position. Second, when the head is hyperextended place a finger anterior to the transverse process of the dislocated vertebra and with the other hand around the head, that is producing the hyperextension, throw the head forward with slight traction and rotation and at the same time push posteriorly quite strongly upon the dislocated vertebra. Follow out the same principles in all cases, no matter in which way the vertebræ are deranged.

There are several methods of applying the underlying principles of adjustment. Relaxation and leverages may be secured in various ways. Preciseness, expeditiousness and skillfulness can be attained only by considerable personal experience.

In cases where the lesion is between the skull and atlas have the patient sit on a stool with the back part of his head against your chest, and reach around the head with one hand under the chin; then with the other hand around the transverse processes of three or four upper cervical vertebræ pull the spinal column toward the median line, while at the same time lifting up on the skull with the other hand and throwing the skull toward the median line. The object of lifting up on the skull is to relax and disengage the articulations, by inhibition, traction and rotation, between the occipital bone and atlas. This is one method applicable to the various lesions of the occiput, which are of frequent occurrence.

In treating the =pharynx=, =tonsils= and =larynx=, outside of correcting spinal lesions, an anterior treatment to these organs is very effective. Examine the deep muscles beneath the angle of the jaw when the pharynx and tonsils are involved; and when the larynx is affected note the condition of the muscles on either side of the larynx. After locating deeply seated contracted muscles in the region of the angle of the inferior maxilla place the fingers over the contracted tissues, and then by a downward, inward sweeping motion toward the median line the muscles may be readily relaxed. When treating the larynx relax the tissues on both sides by an upward, inward movement. These treatments are very effectual when applied directly to the disordered tissues.

Attention should also be given to the lymphatics. In simple infections treat the glands very lightly but attempt to break down the surrounding edematous barrier. Release all the tissues down to and including clavicles, first ribs and pectoral and axillary regions.

To treat slight lesions of the =inferior maxillary= articulation, stand at the head of the patient when he is lying down and hook the fingers about the jaw just in front of the angles, and with the thumbs over the bridge of the nose have the patient open the mouth while considerable force is exerted against his effort. This reduces any slight dislocation of the inferior maxilla. When the jaw is completely dislocated place a piece of wood or hard substance between the molars and exert pressure upward and backward on the chin. If the dislocation is bilateral work on one side at a time.

The object of treatment to the =face= is to stimulate or inhibit points of the fifth nerve that come near the surface (see neuralgia of fifth nerve). While the patient is lying flat upon the back carefully stimulate these various points, especially the supraorbital and nasal, with a downward and outward movement, or inhibit as indicated.

In treating the =scalp= relax the muscles over the scalp thoroughly. This is secondary treatment to correcting the innervation to the scalp at the upper four or five cervical vertebræ.

In cases of pharyngitis, tonsillitis, croup, hay fever, etc., an effective local treatment may be given through the =mouth= upon the soft and hard palate. Introducing a finger into the mouth clear back upon the roof of the soft palate, and with a downward and backward sweeping movement from the median line on either side toward the tonsils, considerable relief can be given the patient. This treatment relaxes the tissues, relieves the congestion, and gives a stimulating treatment to the local nerves. A treatment of the same nature may be given over the hard palate to affect the palatine nerves, especially in hay fever, when the itching of the palate and sneezing are extreme. In cases of young children it is best to protect the finger by wrapping a piece of cloth around it.

An osteopath should never give a manipulation or movement unless he understands why. Just as soon as one gives general imitating movements, from that moment his work is not that of a scientific osteopath, but of a Swedish movement curist and masseur and a poor one at that. The osteopath's work is to locate the anatomical derangement and correct it, as a mechanic would adjust any disordered mechanism. General treatment amounts largely to naught, although in some few instances it is of benefit.

To give a detailed description of the treatment of all lesions that may be found in the cervical vertebræ would be impossible in this sketch; only a general survey of the work can be given. Each case calls for special treatment, but the same general principles are applicable in each case. If there is any one thing that should be eliminated from osteopathic treatment it is those mechanical routine movements of rotating, flexing, extending, and various Swedish-movement-massage-like manipulations that certain osteopaths give in each and every case. It shows that they are imitators and do not have a correct conception of osteopathic therapeutics. True it is, that routine movements will have stimulating and other effects upon the system. But does the body require such treatment? Is it lack of exercise on the part of the patient? If it is, then let the patient exercise himself. You do not want to lower yourself to be a mere "engine wiper," or an exerciser. If it is not the lack of exercise and the system is in need of certain treatment, then seek the cause and apply a specific treatment. Do not hide behind generalities.

=The Ribs.=—In correcting dislocated ribs many methods may be employed, but all are subject to the same principles as given under the treatment of the neck and head.

One of the best methods to correct typical ribs is to have the patient upon the side with the side of the affected ribs upward. Find out exactly the nature of the dislocation, i. e., what is the relation of the dislocated rib to the other tissues. Note whether the rib is upward, downward, inward or forward, locate exactly the dislocated rib. Then, while standing back of the patient, place your fingers upon both ends of the rib. Place your fingers in such a manner that when the proper time in the procedure arrives, all that will be necessary will be to push the ends of the rib into their articulations. For instance, if the rib is raised anteriorly and lowered posteriorly, you will place the fingers on the sternal end, above the affected rib and the fingers on the vertebral end, below the rib, so that when the rib has been released from its abnormal position it may be slipped into normal position. After having placed the fingers in the exact position necessary, have an assistant take the arm and draw it obliquely across the face, while at the same time the patient takes a forced inhalation. The object of drawing the arm across the face and the deep inhalation is to exaggerate the lesion—to draw the ribs out of their locked position—so that the fingers upon either end of the rib may push the rib into normal position. Drawing upon the arm raises all the upper ribs as well as the dislocated typical rib, principally by the use of the serratus magnus; also inhalation has an effect to throw the rib outward and upward and thus away from its articulation. Thus after the lesion has been increased sufficiently to loosen the rib from its abnormal position, the arm is relaxed, the patient exhales, and the fingers upon the ends of the rib correct the dislocation. This treatment is used to the greatest advantage when there is a dislocation of a typical rib; it can be given while the patient is lying down or sitting up, although the former position is preferable.

An excellent method, when the =sternal end= of the rib is dislocated is to have the patient sit upon a stool with his back toward the physician; then by placing the knee in the back (while standing up, or easier still for the physician to sit upon an operating table back of the patient) over the vertebral end of the rib so that the rib may be held rigid posteriorly, reach around with one hand over the dislocated end of the rib and place the fingers upon the rib in the direction dislocated; so that when the rib is sufficiently released from its abnormal position it can be readily pushed into place; then with the other hand under the axilla of the arm on the affected side, pull up and back on the shoulder, so that the rib may be pulled away from its sternal articulation; and at the same time have the patient take a deep inhalation so as to aid in throwing the rib outward, upward and away from its sternal attachment; then when the end of the rib has been released sufficiently, relax the hold underneath the axilla, have the patient exhale, and slip the rib into its normal position by the fingers over the end of the rib. This is an excellent method. It is easy to give and does the work admirably.

Practically the same procedure may be gone through when the =vertebral end= is dislocated, by changing your position to the front of the patient, but there is danger of the knee slipping off from the sternum during the operation and injuring the ribs. Several other

treatments may be given to correct dislocations of the vertebral ends of the ribs. For example, while the patient remains sitting the osteopath stands in front of the patient and reaches around both sides upon the angle of the ribs; then with an outward and upward movement of the fingers upon the angle of the ribs, they are pulled away from their locked position and allowed to slip into normal articulation. This treatment is applicable only when the ribs are dislocated downward, but it is one of the best treatments for such cases.

Another method oftentimes employed in correcting dislocations of the vertebral end of the ribs is to have the patient lie flat upon the side with the affected side upward; then by flexing the arm on the forearm and placing the elbow against the chest or abdomen reach over the patient upon the angle of the dislocated rib and pull it away from the vertebra; when it is pulled away from the spinal column sufficiently, push upward or downward on the angle of the ribs, as the case may demand. The elbow placed against you gives complete control of the patient and aids, by your weight, in throwing the rib upward or downward.

A treatment somewhat like the preceding one which is commonly employed, is to reach underneath the patient's upper arm, when he is lying upon his side, with the arm extended upward across the face; then by placing the fingers of the hand underneath the patient's arm over the angles of the affected rib or ribs and reinforcing the hand by the fingers of the other hand an upward, outward and rotary movement can be given the ribs, which pulls them out of their abnormal position and allows them to return to their normal articulations.

An effectual treatment to spread and raise the upper ribs is to have the patient flat upon the back, and with the fingers of one hand underneath the angles of the ribs and the other hand upon the elbow of the patient's arm of the same side throw the patient's arm across the chest transversely and bear down upon the elbow, at the same time spring upward and outward on the angles of the ribs with the other hand. By throwing the arm across the chest and bearing down upon the elbow a strong leverage can be obtained upon the upper ribs, especially those between the scapulæ. This treatment is very efficacious in certain lung and heart diseases.

Still another method of adjusting ribs is to have the patient flat on his face upon an operating table with the arms hanging down on both sides of the table and a small pillow or folded blanket beneath the upper part of the chest; then standing beside the table, or better still, with one foot upon a low stool and the knee of the other limb upon the table in such a manner that one is directly over the patient's dorsal region one is then in a position to have full control of the vertebral end of the ribs. If the ends of the ribs are displaced downward, placing the thumbs over the angles of the ribs and pushing upward and outward on the angles, the ribs can be very readily crowded into position. If the ribs, especially between the scapulæ, are dislocated in any direction, they may be quite readily corrected by placing the hand over the shoulder posteriorly and throwing it outward and upward and away from the spinal column in such a manner that the ribs are pulled away from the abnormal position; then upon relaxing the hold upon the shoulder with the one hand, the fingers of the unemployed hand may push upward or downward, as the occasion requires, on the angles of the affected side so that the ribs may be slipped into place.

Many times one is obliged to treat the ribs of one side as a whole. In such instances the ribs are almost invariably thrown downward except on one side of scoliosis of the dorsal region. Several methods may be employed to raise the ribs. Probably the best method is to have the patient upon the side and with one hand upon the angles of the ribs and the other hand holding the wrist of the upper arm of the patient, an upward lifting movement is given both upon the angles of the ribs and upon the arm of the patient while the patient inhales. The work upon the angles of the ribs is to raise the ribs directly; the work upon the arm is to raise the ribs indirectly, principally by the use of the serratus magnus. Another effective treatment is to have the patient upon the back and with one hand over the anterior ends of the ribs and the other hand over the angles of the ribs an upward movement is given them by springing the ends of the ribs toward each other and by strong inhalation on the part of the patient. This treatment is most effective where the false ribs are at fault and especially in case of hemiplegia. While the patient is upon the back an assistant may take hold of the arm and draw it upward over the head of the patient, producing considerable additional upward tendency of the ribs, and the physician giving the same treatment of the ends of the ribs as before; or the physician may take an arm in one hand and raise it above the head of the patient and with his other hand around the angles of the ribs, and the patient inhaling deeply, the ribs may be raised.

A treatment used a great deal in raising the ribs as a whole is to have the patient sit upon a stool, and reaching around the patient from the front, place the fingers upon the angles of the ribs and raise them upward on both sides at the same time. This treatment can also be given by standing behind the patient and reaching around upon the anterior ends of the ribs and lifting upward while the patient aids you by deep inhalation. Remember that many times the ribs are drawn downward by contraction of the muscles, due to atmospherical changes and slumped postures. One should begin at the upper ribs in all treatments where the ribs are to be raised, as a whole, and work downward.

To correct the =first= and the =floating ribs= a different treatment has to be given than the foregoing.

An =upward displacement= is the most common lesion of the =first rib=. To correct such a dislocation, have the patient sit upon a stool and with one hand pull the head to the opposite side in order that the lesion may be exaggerated by traction of the lateral muscles of the neck (principally the scaleni) upon the rib; this disengages the rib from its abnormal position; then with the fingers of the other hand upon a point midway of the ends of the rib, exert a downward pressure at the moment the extended head is relaxed describing a short arc. But don't relax head until readjusting pressure is exerted upon rib. If the patient is unable to sit up, and it is not best to give the foregoing treatment, have the patient flat upon the back, with one hand take hold of the arm on the affected side and pull down and out upon the shoulder so that the rib may be somewhat drawn away from its articulation and released from its position; then with the fingers of the other hand upon the center of the rib, or its highest point, press downward when the hold upon the arm is being relaxed. Correction of an upper displacement of the first rib is an every day occurrence. =Downward dislocation of the first rib=, is rare. To reduce this dislocation, place the thumb beneath the vertebral end of the rib, and with the other hand lift up strongly on the shoulder from beneath the axilla, at the same time exerting pressure upward with the thumb on the end of the rib.

The =floating ribs= may be dislocated obliquely downward, or the free end of the rib may be caught underneath the end of the rib above. In either case, in order to correct the displacement, place the patient upon the back with the thigh on the affected side flexed upon the abdomen so that the tissues about the field of operation are relaxed; then bear down carefully but firmly over the free end of the rib with the fingers until one finger can be hooked underneath the end of the rib; then with the other hand over the vertebral end of the rib, have the patient take a deep breath, at the same time springing the ends of the rib toward each other, thus relaxing the rib from its locked position; then have the patient exhale quickly and at the same time spring the rib into its normal position. It oftentimes requires repeated trials, especially in stout persons, and quite often the operation is painful to the patient. It is necessary that one should understand this operation thoroughly, as it is one of the most common treatments in osteopathic practice. The floating ribs are very liable to dislocations and may be the cause of many pains in the side, disturbances of the vessels as they pass through the diaphragm and inflammation in the iliac region. A palliative treatment may be given the floating ribs by having the patient lie flat either on the back or on the side; then place the hand near the vertebral end of the ribs and raise them upward while the patient takes a deep breath.

Treatment of lesions between the =manubrium= and =gladiolus= are best given by placing the patient with the face downward upon the operating table, and having the articulation of the manubrium and gladiolus just over the edge of the table. An assistant should hold the patient firmly upon the table while hyperextension or flexion, as the case may require, with traction, is exerted upon the head, neck and shoulders, and manipulation of the articular points is given to reduce the dislocation. The same principles are employed here as in correcting lesions elsewhere.

Correction of the =cartilages along the sternum= is very easily accomplished by having the patient sit upon a stool and the osteopath standing behind the patient places a knee in the back; then reaching around with one hand over the cartilages and the other hand underneath the axilla, execute the same movement as given in correcting dislocations of the sternal ends of the ribs.

A treatment sometimes used to release a depressed condition of the =cartilages= of the =false ribs= is to stand behind the patient while he sits upon a stool and reach around him with fingers underneath the cartilages and raise them upward as he inhales. By having the patient take a deep breath and then exhale quickly while the fingers are over the cartilages a much better grasp of them can be obtained. This treatment should be carefully given, as there is danger of tearing the cartilages loose from the ribs.

=The Dorsal and Lumbar Spinal Regions.=—Here, as in other regions of the body, before an attempt is made to correct the vertebræ the muscles should be thoroughly relaxed. One of the easiest methods to relax the muscles is to have the patient lie upon the side, and then by standing in front of the patient and reaching over him with the fingers upon the contracted muscles an upward and outward rotary manipulation is given; or the patient may sit upon a stool while the physician stands in front with the arms around the patient and the fingers over the contracted muscles manipulating them upward and outward. Another very easy method is to stand behind the patient while he sits upon a stool and place a thumb over the contracted fibres, with the other hand underneath the axilla lifting the shoulder upward and backward so as to favor a relaxation of the muscles, while the thumb manipulates them.

In relaxing the =muscles= of the =lumbar region= have the patient on the side upon the table; then flex the thighs upon the abdomen with your weight against the knees so as to control all movements of the patient; reach over the patient with the fingers upon the contracted tissues and manipulate them outward and upward on either side until they are relaxed. A method sometimes

employed to relax the muscles of the dorsal, lumbar and sacral regions is to place the patient flat on his face upon the table; then by pushing up on the muscles from above downward with the flat of the hand they are easily relaxed. This treatment should be especially given when the patient's muscles are contracted by atmospherical changes and from standing in one position for a long time. When the muscles of the back are contracting they draw downward and many times draw the ribs with them, as well as tensing the tissues over the sacral foramina and obstructing or irritating the sacral nerves. By using the modern table longitudinally relaxing, or stretching, the lumbar and dorsal musculature saves considerable strength and effort of the physician.

To correct =vertebral lesions= of the =dorsal region= the same rules should be followed as in treating lesions of the cervical vertebræ. Treatments may be given with almost equal ease whether the patient is lying on the side or sitting up.

To illustrate the treatment of the dorsal region when the patient is lying down, assume that there exists a lateral lesion, combined rotation and sidebending, between two vertebræ; if the lesion is below the seventh dorsal use the legs as a lever, and if the lesion is above the seventh dorsal use the head and neck as the lever. Have the patient lie upon the side toward which the lesion is pronounced, either reach under the neck or around the limbs with one hand, and with the other hand upon the lesion bend the head and neck or the thighs in such a manner that the angle of the flexion is directly over the break in the spinal column; this is to exaggerate the lesion; then by lightly lifting up on the neck or limbs and with a slight rotation of this lever the flexed parts should be extended, at the same time exerting pressure with the hand over the lesion in such a manner that the vertebra is pushed forward toward its normal position.

Practically, the same treatment is given when a patient is sitting up, with the exception, of course, that the limbs cannot be used as levers. Lesions of the dorsal region or even the lumbar region can be corrected while the patient is sitting up. By this method considerable lifting is done away with. In fact, the weight of the patient can be used to great advantage by substituting it for one's strength. No matter in what direction the lesion is, the physician reaches around the patient's shoulders so that he just holds the weight of the patient from falling to one side or the other; thus with one hand manipulating the lesion the other arm is around the patient guiding the weight of the body in flexion, rotation and extension. It is not always necessary to lift up on the patient but just let the weight of the patient act as strength applied to the power arm. Always make it a point when working upon dislocated vertebræ in any region that just as soon as one has obtained a slight movement in the lesion =do not attempt= to correct it any more for the time being. A slight movement toward the right direction may be all that is necessary to relieve the ill effects of the lesion. In fact it might be impossible to get the lesion anatomically correct as the shape of the vertebra may have conformed in a greater or less extent to its abnormal position.

An excellent method to correct the various combinations of rotation and sidebending of the third to ninth dorsals is to have the patient sit up with the physician either sitting or standing, depending upon height of seat, back of the patient. Have the patient lean back until head is supported upon shoulder of physician, and the anterior and posterior musculature of torso, abdomen and pelvis are thoroughly relaxed. Reach around the patient's chest with one arm, the hand of which is placed beneath the axilla. The thenar eminence of the other hand is placed upon the posteriorly prominent transverse process of the lesioned segment. Then with careful hyperextension, traction, and rotation and, sidebending of the torso, the anchorage is released, care being taken that localization is exact; this moment of coordination is accompanied with a thrust of the thenar eminence upon the transverse process. Relaxation, leverages and thrust must be precise and thoroughly coordinated.

To reduce vertebræ that are =deviated anteriorly= in the dorsal region, especially between the scapulæ, is often a hard matter. A satisfactory method is to stand behind the patient, while he is sitting upon a stool, and reach around both sides of him upon the sternal ends of the ribs corresponding to the anterior vertebræ; then have the patient relax with the head upon the chest, and at the same time take a full inhalation while pressure is exerted posteriorly upon the sternal ends of the ribs. The object of this method is to pull back the rigid ribs (the lungs being filled with air) which are attached to the anterior surfaces of the transverse processes of the vertebræ, and thus upon the anterior vertebræ pushing them posteriorly; all of the muscles of the body being quite passive and the head relaxed on the body, a separation of the vertebræ is accomplished, thus favoring a crowding posteriorly of the subdislocated vertebræ.

To correct =vertebræ= of the =lumbar region= is on the whole much easier than in the dorsal region. Here the legs can be used as levers to great advantage. By the same method of flexion, rotation, and extension, as employed in the dorsal region when the patient is lying on the side, the result can generally be obtained.

Sidebending is the most common single lesion of the lumbar vertebræ, though there may be some rotation at the lumbo-sacral juncture. Occasionally malformation is found at the fifth. To correct the lumbar lesions the following method is often used: place the patient upon the side of the rotation or sidebending with knees flexed, buttocks well back and entire spinal column straight. Next bring torso and head, with spine straight, well forward to edge of table. Then with hand upon ilium tilt it slightly forward, and with other hand upon shoulder rotate entire spine, including head, so that spine is locked and the point of localization exactly corresponds to the lesions. This brings the spine back to nearly a straight position. Next, after a moment or two of tension-relaxation, either thrust back upon the shoulder or forward upon the ilium. Again exactly coordinating localization, relaxation and leverages is the key of the method.

=The Abdomen.=—Direct treatment of the abdomen is given in many diseases of its organs. The patient should lie flat upon the back, the legs flexed upon the thighs and the thighs flexed upon the abdomen, so that the abdominal muscles will be thoroughly relaxed; and then the various organs of the abdomen can usually be manipulated with ease. Remember that in many diseases of the abdominal viscera the treatment of the splanchnics and vagi will be the primary treatment rather than direct abdominal treatments.

In treating the =liver= directly, the ribs over the liver should be raised and separated, and the lower border of the liver manipulated directly, as considerable therapeutic results can be obtained, particularly when the liver is congested and enlarged. Manipulation of the =bile ducts= is very essential in many liver diseases. The treatment relieves congestion of the ducts and removes any collections of mucus in the ducts due to the congestion, as well as freeing obstructed flow of bile. The manipulation should be a deep, downward one, directly over the path of the ducts (from about the cartilage of the ninth rib to the duodenal orifice of the biliary tract, the latter being about one and one-half inches diagonally downward and to the right of the umbilicus). Be very careful when first manipulating, and bear down lightly over the duct so that the structures superficial to it may be relaxed as the duct is deep below the surface of the abdomen. Usually the gall-gladder can be emptied by light pressure over the skin above the cartilages of the eighth, ninth and tenth ribs. The light manipulation acts, probably, by way of the spinal segment, as a stimulus to the dilators of the sphincters of the gall-bladder. Very likely through reciprocal innervation relaxing the sphincter of the bile duct will contract fibres of the gall bladder.

Manipulation of the =stomach= has considerable effect in strengthening its circular fibres and toning up the coats in general. In cases of gas formation, the gas in some instances may by manipulating over the stomach, be forced through the cardiac or pyloric orifices.

Direct treatment over the =spleen= by raising the eighth, ninth, tenth and eleventh ribs of the left side is effectual in congestion and enlargement of the organ.

In thin subjects the =kidneys= can be treated directly by pressing down carefully but deeply over the kidneys, and lightly crowding them upward and outward. This treatment also has some effect in relieving contracted tissues about the renal vessels and kidneys.

Treatment to the =intestines= through the abdomen is an effective treatment. In the various obstructions to the intestines, constipation, etc., the direct work is essential. Treatment of the intestines is to correct any abnormal position that they may have assumed, to relieve constrictions of the gut caused by contracted tissues, to relieve impactions and adhesions, to increase peristalsis and to tone up the intestinal coats in general. The treatment consists in a manipulation of the intestines, especially in the right and left iliac fossæ, and the pelvic colon, ascending colon and duodenum, as impactions and prolapses of the gut are more liable to occur at these points than in any other locality. In manipulating the intestines, work for a definite purpose and not give a general kneading treatment unless the walls of the abdomen and the coats of the intestines are weakened; in the latter case the spinal treatment is the primary one. In treating over the iliac region, draw upward and inward on the folds of the gut. It is claimed by some authorities that nerves pass from the cutaneous surface of the abdomen directly to the intestine by way of the peritoneum; if such is the case, manipulation of the abdominal walls would have direct effect upon these nerve fibres. The abdomen may be treated when the patient is sitting up, but the treatment is not satisfactory. (See Prolapsed Organs).

=The Pelvis.=—The treatment of the pelvis is easy, but the difficult work is in making a diagnosis of the position of the pelvic bones. The pelvis is especially apt to become deranged by jars and falls. Some of the most successful osteopathic results have been obtained in correcting the pelvic region.

To relax the muscles over the pelvis, the patient should be on the side or upon the face; then relax the muscles by manipulating them upward, chiefly those over the sacral foramina. It is a good rule to adjust the lumbar first owing to release secured to the

nerves supplying pelvic muscles and also to the fact that many pelvic distortions are secondary or compensatory to lumbar lesions. The easiest method to correct the innominata is to have the patient lie upon his side; then by standing in front of the patient slip one hand between the thighs and grasp around the tuberosity of the ischium, and with the other hand upon the crest of the ilium, the innominatum can be moved upward or downward and forward or backward (wheel and axle principle). Simply pulling or pushing upon these two points in whatever direction necessary is all that is required providing the soft tissues are thoroughly relaxed. By having the patient flat upon the back practically the same treatment can be given, but not to so great an advantage. In cases where the ilium is posterior and the ischium anterior, the physician may stand back of the patient, while he is lying upon his side, and place one knee against the sacrum and with one hand upon the ilium, with the other take hold of the ankle of the affected side (the involved side being uppermost in all cases where the patient is lying upon his side); pressure can be exerted upon the ilium and the limb pulled backward, thus correcting the derangement. This treatment should be avoided as much as possible, as there is considerable danger of pulling back too severely and injuring the patient; the lever is long and the amount of force exerted upon it cannot be judged precisely.

Another method is, with the patient on the back, flex and evert the knee to the side so the side of the foot lies flat on the table. Grasp the ankle with one hand and with the other on the crest of the ilium of the opposite side then, by pushing down firmly on the knee the articulation is gaped and at the same time the operator pushes with his body against the knee with a sharp thrust. This may have to be repeated a few times before the articulation is released and if one is keen he will easily detect the slight concussion carried down the femur as the adjustment takes place. This will correct a forward and downward innominate. For an upward and backward one, place the patient in exactly the same position and go through the same motions except that the knee is pulled toward the operator. If the desired “chug” is not felt and adjustment is not definite, the leg may be pulled down rather smartly by the ankle to a parallel with the other. This is a technique that is easy, both for the patient and operator, and will correct any but the most stubborn.

In the case of a greatly relaxed and atonic condition of the ligaments of the pelvis much trouble is experienced, often, in making the adjustment permanent. Many suggestions have been made and most of them useless but, probably the use of a belt of non-elastic webbing about two inches in width buckled tightly around the pelvis just below the anterior spines will do as much as anything and is a procedure well to follow in all such cases. Where there is a pendulous abdomen a support in the shape of a simple belt which should be so fitted as to act as a sling will transfer the weight of the abdominal viscera from the muscles, already stretched and atonic, to the belt and put the burden over the sacrum. This prevents the pulling of the innominatum in lesion again. Overcorrection is suggested as a means on the ground that it sets up irritation and induces fibrous ankylosis and for the same reason W. W. Howard places his patient prone and with thumb works the ligaments associated with the joint until they are thoroughly inflamed. The patient is then put in bed a few days and after the inflammation has cleared up the ligaments will be found to have shortened.

To correct a rotary lesion between the pelvis and fifth lumbar the patient should be placed upon the side, and with the body held firmly, the pelvis can be forced backward or forward as the occasion demands. (See Coccyx).

=The Legs.=—The origin of many symptoms manifested in the legs, as in the arms, are due to spinal lesions corresponding to the region of innervation to the affected tissues. The derangements of the pelvic bones are a frequent source of symptoms that are referred to the legs and feet. The osteopath finds that a slight dislocation of the hip may occur which is especially likely to affect the knee. This partial dislocation is apt to be an upward-posterior one; the head of the femur resting in the upper and posterior part of the acetabulum. Many diseases of the legs and feet are due to local displacement of the bones. The method of treatment is the same as given in surgical works. (See Sprains).

A general treatment of the legs and thighs is oftentimes necessary; it consists of flexing the thighs quite firmly upon the abdomen, and executing thorough external and internal rotary movements of the thighs and legs. In a few cases both limbs are flexed strongly at the same time upon the abdomen. After giving these movements manipulation over the saphenous opening and beneath the popliteal space is performed. This general treatment tends to increase the circulation of the entire limb and to relax thoroughly all contracted fibres.

=The Arms.=—In treating the arms, care has to be taken that the affection is not due to spinal derangements; otherwise the arms are manipulated according to the disorder. Complete dislocations of the shoulder comes under the province of surgery. Many times the osteopath locates slight or incomplete dislocations of the shoulder. Partial dislocations of the shoulder are generally anterior. (See Sprains).

In cases where pain exists in the shoulder or arm, outside of locating the cause in the shoulder joint, the affection may be due to fibres contracting over the coracoid process, or a dislocation of the second or third rib, and in some instances the clavicle is deranged. Special care should be given to a possible bursitis and tendo-synovitis. Occasionally muscular fibres may slip out of the bicipital groove. Dislocations of the bones of the arm are treated according to surgical methods. The pains and various troublesome symptoms that may be manifested in the fingers or the hands are oftentimes caused by slight dislocations of the elbow, shoulder, ribs, or vertebræ, as low as the sixth to eighth dorsals.

=The coccyx.=—The coccyx, owing to its exposed position and rather unstable attachment, is subject to many injuries; more indeed than come to notice. Its injury results in many local and general disturbances owing to its close relation to the sympathetics. Successful treatment of deviations often bring startling results. They may be divided into =fractures= and =displacements=.

In =complete= or =partial= fracture of the coccyx, as well as in dislocation, if the patient can be seen with reasonable promptness after the accident much can be done for relief of the pain and the prognosis is good for complete recovery.

Examination should be made externally and internally and after the condition is diagnosed about the same procedure is indicated for any of the conditions. With the patient on the left side introduce the right index finger, well lubricated, into the rectum and carefully relax all tissue within reach of the tip. If there are spasms of the coccygeal muscles, inhibition of the anterior nerves will quiet them. When this has been done place the left index finger externally along the body of the coccyx and holding it firmly both within and without release it longitudinally and then adjust. After this has been done it is well to hold it there until all danger of returning spasm, which might displace it again, is over, when the finger can be withdrawn.

The pain following will depend on the severity of the injury, but will keep up more or less constantly for several days. When severe, relief is often given by introducing the finger and relaxing contracted tissue which is pulling it from its position. Hot water bags placed next to the part will be of benefit. The bowels should be kept confined for forty-eight hours if possible in cases of fracture. Watch carefully the progress of union that the bones are _in situ_ so there will not be deformity.

In diagnosing the first injury be sure that there is no splitting of the first segment or splinters which may require surgical interference. In old cases of fracture where there is complete bony ankylosis it is not justifiable to attempt any change, but where there is motion and a fibrous union, after preparatory treatments about one week apart, it can usually be replaced. Look well to any muscular contractions which might interfere with it. Force must never be used nor any attempt to replace until it has been first released from its articular attachment. In the various forms of =displacement= the same technique applies as in fractures, or the finger and thumb of one hand may be used, the tip of the finger internally at the sacro-coccygeal articulation and the thumb externally at the same point. Complete control of the part is secured in this manner. Great care must always be used in treatment of any displacement of the coccyx. Contractions of its muscular attachments will often cause deviations in contour. Removal of the irritation and relaxation will allow it to assume its normal position.

=The sacrum.=—Adjustments of the sacrum as distinguished from the ilium in strictly innominate lesions are not many. When posterior with the patient on a stool the knee of the osteopath coveted by a pillow and placed against the sacrum and both hands grasping the anterior borders of the ilia, strong traction will move it into position. In a downward displacement with the aid of an assistant from behind holding the crests of the ilia firmly as the patient sits on the table, the osteopath in front clasping both arms about the patient and with a rocking motion from side disengages the sacrum and at the same time lifts it into position.

For anterior displacements use the technique described in replacing upward and backward innominate dislocation first right side and then left, which will result in correcting the lesion.

The preceding osteopathic technique includes a few of the treatments given by the osteopath. Although many osteopaths use methods not given here, those outlined are sufficient for illustrative purposes. A point which cannot be too thoroughly impressed upon the student is that osteopathic treatment is in reality =constructive= work, that is, readjustive, not only in detail, but in viewing the body structure as a whole. Detailed readjustment is an essential, still do not lose sight of the relation of the part to the whole. In our distinctive work anatomical construction is the basis of physiological function, although physiological stimulus is essential to anatomical development.

=How often to treat.=—How often to treat a case depends entirely upon the nature of the disease from which the patient is suffering. Just as in giving drugs the frequency of treatment is entirely dependent upon the seat of the disease and its severity. Acute cases require a thorough treatment at least once daily, and many times in severe cases the treatment has to be repeated

several times daily. In subacute and chronic cases, as a rule, treatment should not be given as often as in acute cases; possibly once a day, but usually alternate days is better. In office practice cases are commonly treated two or three times weekly. Still it is better not to treat some cases oftener than once a week.

There is more danger in treating too often and too long than in not treating often enough. The distinctive work of an osteopath is to correct disordered anatomical structures; and when a certain derangement has been corrected the tissues should have rest and plenty of time for repair. When treatments are given often, it simply keeps the tissues in an irritated state and nature does not have time to heal the diseased tissues. Always make it a point at each treatment to correct some definite lesion, and when the work is accomplished let the parts alone until the tissues have recovered as much as possible from the effects of the previous treatment before another treatment is attempted. The reason why some cases do not get cured under osteopathic treatment is simply because the osteopath keeps the diseased tissues in an aggravated state by the constant treatment so that they do not have the least chance to heal; the physician is thus adding irritation to the disease.

It is only by experience that one can tell how often to treat. Each case is a special study; what would be quite sufficient for a certain individual with a given disease would not be at all suitable for a second individual with the same disease. As in drugs what is suitable for one person would not be adapted to another, because the make up of each individual is entirely different; but here the parallelism diverges, for in drugs there is a foreign agent introduced into the system, while in osteopathic treatment the curative agent is entirely harmonious with the idiosyncrasies of the individual. It is for this reason that experience in practice is so essential.

Most cases should not be treated, as a rule, after a meal unless the patient is suffering from some digestive disturbance; for treating other regions of the body outside of the digestive tract causes more or less stimulation of the parts treated and thereby draws blood away from the organs of digestion. Cases of disordered brain circulation, where the patient is unable to rest or sleep at night, should be treated at about their retiring time so that the circulation of the body may be equalized, thus giving the patient undisturbed rest.

To show in a practical way the methods of experienced osteopaths in this matter G. J. Helmer[32] is quoted: “I submit the following table to illustrate the frequency of treatment in one hundred cases taken from my practice: one case three times per week, sixty-three cases two times per week, twenty-two cases one time per week, nine cases once every two weeks, five cases once every four weeks. Comparing the present with the past, I find I am lengthening the time between treatments with much better results.”

Another very practical side of the question and one which will be greatly appreciated by the patient, is the lessened cost for the same result in the less frequent treatments, as well as the saving in time. With the loss in going to the office, rest after treatment, not to mention possible wait while there, three times weekly represents more time than the average person can well spare and not infrequently will deter him from continuing. More especially is this true of those coming from a distance.

=Length of Treatment and Overtreatment.=—Naturally the length of treatment depends upon the case at issue and nothing more. There is no reason why any two cases should be treated for the same length of time unless they present identical lesions and then the personal equation of the two might present such a wide difference of aspect as to forbid such a proceeding.

The question of time has no place in the matter, save that it must not exceed physiological limits and be sufficient for the needs of the case. The patient should understand at once that it is to accomplish a specific purpose that the treatment is given, just as definite as a surgical or dental operation, and when the work is done it is time to stop. He would hardly be attracted to the dentist who guaranteed to use forty-five minutes in extracting a tooth. Good judgment is required in this as in all matters pertaining to osteopathy. There is a generally expressed opinion among the older osteopaths, based on experience, that: first, a short specific treatment is productive of best results and, second, treatments given under high tension when quick work is necessary are most satisfactory. Long treatments are debilitating and over stimulation amounts to inhibition. Further, in a long treatment it is necessary to go over the whole body, thus dispersing the vital forces (which have been stimulated for healing and upbuilding the pathological area) to parts not involved, thus defeating the very purposes intended. Dr. Still always advocated and gave the short, specific treatment.

The point always to be considered is the individual characteristics of the patient, and effects of the first treatment should be carefully observed. After a patient has been under treatment for any considerable time it is well to give him a vacation from treatment, and it is remarkable what improvement will be shown at times by such a measure and how seldom he will lose ground. Dr. Still presented this subject vividly as follows: “To treat the spine more than once or twice a week and thereby irritate the spinal

cord, will cause the vital assimilation to be perverted and become death producing by effecting an absorption of the living molecules of life before they are fully matured and while they are in the cellular system, lying immediately under the lymphatics. If you will allow yourself to think for a moment of the possible irritation of the spinal cord and what effect it will have on the uterus, for example, you will realize that I have told you a truth. Many of your patients are well six months before they are discharged. They continue treatment because they are weak, and they are weak because you keep them so by irritating the spinal cord." It is not a rare experience for a patient to leave apparently with little or no improvement only to report a complete recovery a little later.

=Misapplied Treatment.=—Probably in spinal treatment more risks are taken than in any other region of the body. To us as a school it is by far the most important and interesting area we have to treat, consequently it is not surprising that various general treatments and methods have been devised with the idea of getting quicker and easier results. Herein lies the danger outside of mistaken diagnosis, for short cut treatments can never take the place of time and skill. Technically speaking, if one thoroughly understands the philosophy of osteopathy and is conversant with the underlying principles of its therapeutics, there is absolutely no danger of even the slightest injury. It is the one who takes chances by not properly diagnosing and by not being cautious enough with delicate persons when applying his treatments that is apt to overstrain some tissue or organ and otherwise do bodily harm. Of the treatments considered dangerous not one of them is without merit if judiciously applied, but unfortunately in many cases they are in general and indiscriminate use. It is well to remember that we are moving structures which have never been moved before and that time enough has not elapsed to observe what the ultimate result may be. Again, in adjusting a subluxation of the spine do not forget that the force necessary for that adjustment, if misapplied, is sufficient to produce a lesion, and there is no doubt that this has happened. Your patient's interests are above everything and must never be sacrificed for any reason whatever, so if at any time there is uncertainty always give the patient the benefit of the doubt. On the other hand the osteopath must have the courage of his convictions and fortunately when these are coupled with good judgment the results are all that could be desired. The following should be used with great caution if used at all:

First, =Indiscriminate stretching= of the spinal column with the aid of an assistant. It is not good osteopathy although there are some cases where it may be beneficial. While not specially dangerous, generally, in delicate patients, elderly people, arteriosclerotic conditions, and in some stages of Pott's disease it is absolutely contraindicated. Moreover in most spinal cases except impacted vertebræ and symmetrical curvatures the stretching of the vertebral ligaments locks the lesion firmer.

Second, =Extreme rotating= of the cervical region. This cannot be considered good treatment in any case with the exception of the muscle stretching. On the contrary it is dangerous; first, it is not osteopathy for it is not specific; second, the nervous shock is severe, an important consideration in delicate people; third, the cervical ligaments become stretched and the vertebræ are easily displaced, while damage to a diseased vertebra, an aneurism or in arteriosclerosis would be irreparable. No other region of the body should have greater care in treatment than the neck.

Third, =Hyperextension= of the spine with the patient on his face. This treatment is rarely indicated. In fact, it is barbarous and a relic of an early day. Possibly more cases have been injured by this treatment than all others combined.

Fourth, =Rough separating= of the vertebræ and ribs while the patient is on his face. This is a most excellent treatment in many cases, but great judgment is necessary. Delicate patients, heart disease, and necrosed vertebræ and ribs should be carefully excluded.

Fifth, =Innominate adjustments= such as placing the patient on the side and putting the knee against the sacrum while grasping the leg at the knee. Or, the placing of the patient face down with one hand on the sacrum and the other holding the knee. In both these there is a tremendous leverage and in the latter the strain is at the lumbar rather than where needed. There are other unnecessarily risky methods for this operation, while it is easy to perform in most cases and without danger.

Sixth, =Abdominal treatment= gives wonderful results when intelligently applied, but it may be productive of great harm in conditions of tumors, malignancy, and pus formations.

=Misapplied treatment= is always dangerous, no matter to what part of the body given, and it is proof of wrong diagnosis when given. As a rule treatment is given without proper diagnosis in such cases, so a misapplied treatment has two interpretations—first, ignorance; second, laziness. In the former lies the greater danger for ignorance coupled with force and lack of skill is an appalling combination.

Cases are frequently reported where tumors have passed from the vagina, rectum, nose, etc., the osteopath thinking it was the result of good treatment, without considering that it was simply the breaking of a long pedicle with great danger from hemorrhage. The greatest care should be exercised in treating cases where aneurism, osteomalacia, and arteriosclerosis are present, also in the leg treatment of tabes dorsalis and in the weak, thin ribs of elderly people and those with a gouty or rheumatic diathesis. Imagine treating an abscess directly, yet it has been done, as have varicose veins with the terrible danger of rupture and embolism. Aneurisms have been ruptured in the same way.

One could go on indefinitely with this subject, but to sum up: if the osteopath is not familiar with the feel of the living anatomy in its giving and resisting under treatment both in health and disease and does not know his osteopathy, nothing can prevent him doing harm. A successful practitioner means an understanding of pathology, then experience plus common sense.

FOOTNOTES:

[31] See Ashmore's Osteopathic Mechanics.

[32] Journal of the American Osteopathic Association, Dec., 1903.

OSTEOPATHIC CENTERS

"Osteopathic spinal centers" was a term commonly used in the early period of osteopathic development. From the facts, first, that a few centers have been actually determined in the cord, viz., genito-urinary, vasomotor, etc.; second, that the innervation from the spinal segment to various thoracic, abdominal and pelvic viscera correspond with a considerable degree of accuracy to certain vertebral sections, and third, displacements of tissues of the spinal column affect viscus integrity, depending upon the locality of the structural perversion as to the organ involved and is a clinical observation of great import, arose the misnomer "osteopathic centers." For one to ask what "centers" should be "treated" in this or that disease shows a lack of the conception of osteopathy as if he asked what "movements" to give when "treating" a certain disorder. It is as unosteopathic, as it is unscientific, broadly speaking, to suppose osteopathic technique implies the application of movements to certain nerve centers.

Osteopathic Stimulation

"Osteopathic stimulation" is another term loosely used without extensive clinical experience to support it. Mechanical stimulation is frequently utilized in the physiological laboratory. But to employ it extensively and comprehensively in the treating room or at the bedside the therapeutic potency of it will be found wanting; that is, to employ it to the exclusion of that most important basic treatment, readjustment, is a great mistake.

Clinically, the pathologically slowed heart may be stimulated by a stimulus to the cervical sympathies, the gall-bladder emptied by a stimulus near the costal cartilages of the ninth and tenth ribs (this is probably via the spinal segments), etc. Normally, these organs and others may be temporarily stimulated. Experimentally, Burns[33] of Los Angeles and Pearce[34] of San Francisco have shown the potency of osteopathic mechanical stimulation. For example, stimulation (mechanical) in the middle and lower dorsal regions irritates and increases peristaltic action and vaso-constriction in the stomach and intestines.

Osteopathic Inhibition

Likewise the term "osteopathic inhibition" has not always been scientifically employed. Mechanical inhibition is probably used less frequently than stimulation but still it is of more importance. Probably the true interpretation of considerable of so-termed stimulatory and inhibitory efforts, is simply one of normalization of tissues, physiologic equilibrium resulting from such changes.

Clinically, to relax contracted muscles by inhibition, to relieve neuralgia by impinging nerve courses, to relax the cardiac orifice of the stomach by pressure at the ninth or tenth dorsal vertebra on the left side, etc., are excellent examples of the therapeutic value of inhibition. Experimentally Pearce and Burns produced the opposite results to that of stimulation. Inhibition in the middle and lower dorsal region caused relaxation of the muscles of both the stomach and intestines, decreased peristalsis, and caused dilatation of the blood vessels.

The employment of stimulation and inhibition rounds out to a certain extent our therapeutics, that is, makes it more practical and specific. We should not, however, over-rate the relative value of stimulatory and inhibitory treatment as compared with the readjustive treatment. Not but what the former is of considerable practical importance, but the point to be emphasized is that it

gives a scientific demonstration of how pathological effects result, if long continued, from the various osteopathic lesions. In a word, it shows the physiological process from cause to effect, or rather a step in the beginning pathological (perverted physiological) in many disturbances.

Therapeutically, all will agree with Cherry[35] that “stimulation and inhibition should be employed in all forms of acute disease as palliative measures until such time as the primary lesion may be removed.”

As a preparation for adjustment of any bony lesion there is no question but that simple inhibition for a brief time in the area will bring about relaxation of soft tissues in a much more satisfactory manner than the usual massage like method. McPherson, Montreal, has developed a technique of sacral pressure which he uses exclusively in his practice. Without going into the merits of his theory there is no doubt that inhibition at the second and third sacral will bring about relaxation of the muscles of the lower trunk in a most gratifying manner. Another thing, if there is difficulty in introducing the finger in making either a vaginal or rectal examination, a minute’s pressure at these points will, in most cases, cause the sphincter to relax so as to cause no discomfort to the patient. This pressure will, also, have a great effect on the hypogastric plexus and the pelvic organs.

Osteopathic Readjustment

Readjustment or adjustment is many times particularly emphasized in this work as the key to osteopathic therapeutics.

If the theory of readjustment can not stand the most searching tests of science osteopathy will have to be relegated to a most subservient place, on a par with massage, Swedish movements, and various medical gymnastics. Consequently the readjustment theory is again referred to, and especially so when the subjects of osteopathic centers, stimulation and inhibition are outlined.

No doubt many stimulatory (so-called) and general treatments exert their greatest influence by inadvertently readjusting tissues. Then how much more effective would the readjustment treatment be if applied intelligently. In certain acute disorders, e. g., “colds,” immediate relief is often obtained by relaxing muscles through either stimulation or inhibition; in reality the final result, as far as the muscle is concerned, is one of readjustment. Likewise in stretching and rotation of tissues and sections of the body the effect may either be stimulatory or inhibitory, and still it may be, also, readjustive.

After all has been said the ultimate physiological effect of any of these treatments, if of any therapeutic value, must be one of stimulation to a part or to the body generally. But there is a vast difference between physiological stimulation and the one method of obtaining the same termed mechanical stimulation. It is not the purpose here to enter into anything like an exhaustive survey of stimulation and inhibition but simply to outline a few practical hints on the relative values. Everyone is aware that overstimulation is equal to inhibition, and even applying it to very delicate subjects the therapeutic end we may wish to obtain may be lost and as a consequence the patient exhausted; whereas at the same time readjustment possibly could have been employed and real permanent effects secured.

So we should whenever possible utilize the basic principle of our therapeutics, readjustment, for this represents in the majority of cases, first, permanent results; second, a saving of much time, and third, less exhaustion on the part of both patient and physician.

McConnell[36] has shown in his series of laboratory experiments on animals the reality and potency of the readjustment fundamental. The effect of malaligned vertebræ and ribs upon contiguous vascular channels and nervous tissues, not only affects immediate skeletal muscles by simple contractions but even produces interstitial myositis. Through narrowing of the intervertebral foramina and tension upon the fibrous tissue anchoring the spinal nerve in its exit, and through pressure and strain on the sympathetics in contact with the heads of the ribs, which are secured there by the parietal layer of the pleura, organs in corresponding cavities become diseased. Some of the diseases produced in the series of experiments were catarrhal and parenchymatous changes in the stomach and intestines, congestion of the liver and spleen, acute nephritis, goitre, inflammation of the lymphatics, edema of the cornea, and degenerations of nervous tissues. Still too much emphasis should not be placed upon the narrowing of the foramen for certain pathologic changes are shown to be due to other conditions than Wallerian.

The osteopath, as stated, may inadvertently correct osteopathic lesions. _Vis medicatrix naturae_ undoubtedly corrects many osteopathic lesions; this is evident from the fact that many bodily strains, sprains, and injuries are overcome naturally or involuntarily, that is, without any voluntary assistance from an osteopath. On the other hand all osteopathic lesions are not due to outside influences or forces, e. g., in pneumonia the severely contracted dorsal muscles often partially dislocate the vertebral ends of the ribs and thus increase the seriousness of the disease; and this is true in many acute conditions wherein visceral changes will reflexly contract spinal muscles and also through these contractions produce osseous lesions. Here is where osteopathic treatment

in acute diseases will not only correct the primary lesion but also these secondary ones and thus abort, or shorten, or lessen severity, or prevent complications of the disease. But it should always be borne in mind that when certain disease processes occur it will take a definite time at best for curative changes to predominate. In other words pathological changes are just as real and potent as physiological facts or anatomical data and the character of the same should always be considered.

Consequently in readjustment work a distinctive etiology and pathology has to be taken into account. The color, contour (whether the lesion is simply a local one or there is a composite or group lesion), condition (irritation, debility, contractions, and tenderness), and movement of the several regions, and the spine as a whole should be noted. And the student should always keep in mind that the osseous vertebral lesion may be, (a) a twist between two vertebræ (this generally means a rotation of one section of the spine on another section), (b) malalignment of several vertebræ (the composite or group lesion), or (c) the impacted or strained lesion, (this is a lesion that Clark attaches considerable significance to, wherein there is injury to the articular surfaces and ligaments without osseous derangement, followed by exudation and other inflammatory products, limited motion, etc.).

VasoMotor Nerves

It is extremely important that the osteopath should be thoroughly conversant with the regions where he may affect the vasomotor nerves to various tissues and organs. Many anatomical derangements undoubtedly involve the vasomotor nerves, and it is therefore necessary to know where they may be affected. The following table is taken mostly from the physiology of Landois and Stirling, but many of the statements have been noted at various times; it is, therefore, impossible to give full credit.[37]

The vasomotor center is in the medulla, consequently the osteopath gives cervical treatment to influence this center. Treatment of the upper cervical region has undoubtedly a marked effect in tending to equalize the vascular system of the body, when it is disturbed.

=Head.=—The cervical sympathetic for the same side of the face, eye, ear, salivary glands, tongue, etc., and possibly the brain. Lesions are found in all the tissues about the cervical region, but usually in the vertebræ, which influence these nerves. Deep contracted muscles oftentimes involve them. The spinal vaso-constrictors for the vessels of the head are from the first five or six thoracics. Many lesions are located in the upper five or six dorsal vertebræ, or corresponding ribs, that have apparently a direct influence upon the vessels of the head. Not only congestive headache and congestion of the brain tissues are influenced by lesions in this region, but disease of the eye, ear and face occasionally arise from such derangements. It is always best when the head, neck or even the arms are involved, to examine carefully this region. Vaso-dilator fibres for the face and mouth are found from the second to the fifth dorsals; these fibres unite almost entirely with the trigeminus, and pass from the superior cervical ganglion of the sympathetic, to the ganglion of Gasser. This fact is of great importance to the osteopath, for oftentimes when inflammation of the face and mouth occurs, lesions may be located along the upper dorsal vertebræ or ribs, or in the deeply contracted muscles of this region. Observation revealed in several cases of erysipelas that the causative lesion was located in the upper dorsal region; and the cases were cured by correcting these lesions, thus showing that probably the vasomotor nerves were the seat of the trouble. Other dilator fibres arise apparently in the trigeminus, for stimulation of this nerve between the brain and Gasser's ganglion causes dilatation of the vessels of the face. The lingual and glosso-pharyngeal nerves are the dilators of the lingual vessels. The sympathetic and hypo glossal are the constrictors; these arise in the sympathetic and reach the nerves by way of the superior cervical ganglion. Stimulation of the cervical sympathetic causes constriction of the retinal vessels. This point is extremely interesting to the osteopath, because diseases of the retina and optic nerve are oftentimes due to subluxated cervical vertebræ, usually the atlas or third cervical. The retinal fibres leave the sympathetic at the superior cervical ganglion and pass along the communicating ramus to the ganglion of Gasser, from whence they reach the eye through the ophthalmic branch of the fifth nerve, the gray root of the ophthalmic, the ganglion and the ciliary nerves. Almost all the fibres to the anterior part of the eye are found in the fifth nerve; this, also, is another important point for the osteopath's consideration. Cases of conjunctivitis, keratitis, corneal astigmatism and diseases about the eyelids and tear ducts are usually caused by lesions to the fifth nerve, due to a deranged atlas or third cervical. The vaso-dilators for the anterior part of the eye, and also dilating fibres to the iris may be affected at the first and second dorsals. This point is also taken advantage of by the osteopath, for lesions of these fibres occur oftentimes at the upper dorsal. It is claimed that important fibres that aid in the control of the metabolism of the retina, may be affected at the fourth and fifth dorsals.

=Lungs.=—Reflex constriction by stimulation of the intercostals, central end of the sciatic, abdominal pneumogastric and abdominal sympathetic. There is not a rich vasomotor supply.[38] The essential feature to the osteopath is that the vaso-constrictors to the lungs and bronchial tubes are very likely to be interfered with by rib and vertebral dislocations, from the second to the seventh

dorsals, inclusive, but chiefly at the third, fourth and fifth. The heaviest innervation being from the third, fourth and fifth spaces, probably explains why asthma is often due to a dislocation of the third, fourth or fifth rib.

=Heart.=—First to fifth thoracic via ganglion stellatum and inferior cervical ganglion. Vasomotor fibres to the coronary arteries are found in the vagi.

=Intestines.=—Sympathetic, chiefly through the splanchnic nerves. Vaso-constrictors of the jejunum from the fifth dorsal down, for the ileum slightly lower and for the colon still lower. There are none below the second lumbar. Dilators are present in the same sheath, but more abundant in the last three dorsals and the upper two lumbars; all probably end in the solar and renal plexuses.

=Receptaculum Chyli.=—Stimulation of the splanclinics causes dilatation.

=Liver.=—The splanchnics chiefly on the right side. The vagus contains vaso-dilators. There are also fibres from the inferior cervical ganglia of the sympathetic.

=Kidneys.=—Vasomotor nerves from the sixth dorsal to the second lumbar, but principally from the ninth to twelfth dorsals, inclusive. In the large majority of kidney diseases, lesions are found from the tenth to the twelfth dorsals. Stimulation of the sciatic centers causes contraction. There are also fibres from the superior cervical ganglion.

=Spleen.=—Vasomotor fibres are in the splanchnics, third dorsal to third lumbar, principally, on the left side. There are some fibres direct from the brain. Stimulation of the vagi contracts the spleen.

=Portal System.=—Fifth to ninth dorsal.

=Generative Organs.=—For Fallopian tubes, uterus, vagina, vas deferens and seminal vesicles, vasomotor fibres are found in the lower dorsal, and the second, third, fourth and fifth lumbar nerves, principally.

=Coccyx and Immediate Region.=—Third lumbar down.

=Back Muscles.=—Dorsal Posterior branches of the lumbar nerves and intercostal nerves. These nerves arise from the gray ramus of the corresponding sympathetic ganglia.

=Arm.=—From the brachial plexus, the sympathetic, inferior cervical ganglion and first thoracic ganglion, and sometimes lower.

=Leg.=—Second dorsal down, the sciatic and crural nerves, and the abdominal sympathetics.

Sensory Nerves

Inhibition of various regions along the spinal column is frequently given by the osteopath to lessen pain. It is only a temporary or palliative treatment, but many times gives great relief. One should inhibit usually over tender points and contracted muscles. These (tender points and contracted muscles) are signs to the osteopath that disturbances exist at these points. The following table is taken from Quain, which is Head’s classification:

=Heart.=—First, second and third dorsals.

=Lungs.=—First, second, third, fourth and fifth dorsals.

=Stomach.=—Sixth, seventh, eighth and ninth dorsals. Cardiac end from sixth and seventh. Pyloric end from ninth.

=Intestines.=—(a) Down to upper part of rectum, ninth, tenth, eleventh and twelfth dorsals. (b) Rectum, second, third and fourth sacrals.

=Liver and Gall-bladder.=—Sixth, seventh, eighth, ninth and tenth dorsals.

=Kidney and Ureter.=—Tenth, eleventh and twelfth dorsals. Upper part of ureter, tenth dorsal. At lower end of ureter, first lumbar tends to appear.

=Bladder.=—(a) Mucous membrane and neck of bladder; (first) second, third and fourth sacrals; (b) over distension and ineffectual contraction, eleventh and twelfth dorsals, and first lumbar.

=Prostate.=—Tenth, eleventh (twelfth) dorsals. First, second and third sacrals, and fifth lumbar.

=Epididymis.=—Eleventh and twelfth dorsals and first lumbar.

=Testis.=—Tenth dorsal.

=Ovary.=—Tenth dorsal.

=Appendages, etc.=—Eleventh and twelfth dorsals, first lumbar.

=Uterus.=—(a) In contraction, tenth, eleventh and twelfth dorsals, and first lumbar. (b) Os uteri; (first) second, third and fourth sacrals (fifth lumbar very rarely).

Other points are used by the osteopath to relieve pain of certain regions, for such the reader is referred to the article on neuralgia; besides many tender points are found along the spine by the osteopath, where inhibition gives relief to the patient, provided such points have a connection with the case in question.

Hot fomentations if property applied, through reciprocal relationship of the nervous system, are of value in relieving pain, releasing spastic musculature and normalizing visceral function. Frequently, in both acute and chronic cases, this is an excellent preparatory measure, to be followed by careful adjustment. It will be recalled that the functional test, movement of a vertebral lesion is of primary consideration.[39]

PATHOLOGICAL SPINAL CURVATURES

SPINAL CURVATURES

Any deviation of two or more consecutive vertebræ from the normal curves of the spinal column is usually termed by the osteopath a pathological curvature. Of the common pathological curvatures of the spinal column there are found: (1) scoliosis or lateral curvature, (2) kyphosis, or excurvation, an antero-posterior curve with the convexity backward, and, (3) lordosis, or incurvation, an antero-posterior curve with the convexity forward.

=Osteopathic Etiology.=—Of primary importance in the causation of pathological curvatures of the spinal column, are injuries to the spine, such as strains, falls, blows, and various physical forces, acting directly or indirectly, as injuries to the chest, pelvis and limbs. The osteopath in his daily work finds more curvatures, as well as acute and chronic diseases, resulting from some simple injury to the spine, as a slip, strain or twist, than from any other cause. The dire effects of any violence to the spinal column cannot be overestimated.

Among =predisposing causes= may be mentioned, continued ill health, general weakness, rapid growth, rachitis, tuberculosis, etc. Any habitual one-sided position may result in a curvature. An injury to the chest, adhesions from pleuritis, chronic liver disease, obliquity of the pelvis producing unequal length of the legs, carrying heavy weights on one side, and various morbid growths of the chest and abdomen, may all produce curvatures. Many cases are found in school children who are growing rapidly, and whose muscular strength and development do not keep pace with their growth. Unilateral atrophy of the muscles, due to central changes or overuse, may be the cause of deviations of the spinal column. Sacro-iliac disease in some instances is a potent factor. Thus there may be a great variety of causes productive of the incipiency, and the spine being strained or irritated at a single point and in

a certain way gradually develops a curvature. Every spinal and innominate lesion should be considered as a potential cause for a curvature.

=Scoliosis.=—This is the most common spinal deformity and is characterized by lateral deviation from the median line. In most cases the curve is to the right in the upper dorsal region, with a compensatory curve in the opposite direction in the lumbar region. The curve being to the right in the majority of cases, is probably due to the fact that most people are right-handed.

=Morbid Anatomy.=—The vertebræ in the region involved are rotated so that their spinous processes point toward the concavity of the lateral curve. The bodies of the vertebræ on the side next to the concavity are thinner, due to absorption; the intervertebral discs are made thin on the same side by pressure and absorption. The ribs are considerably distorted, depressed on the concave side and prominent on the convex side. The ligaments on the concave side are contracted, and stretched on the convex side. The muscles on the concave side are more or less contracted, and on the convex side they are stretched, causing atrophy and fatty infiltration of their tissues.

=Kyphosis.=—This may be a slight posterior curve really amounting to nothing, or it may be a very grave pathological condition as in Pott's disease. Therefore it is very necessary that one should make a most careful diagnosis (see Pott's disease).

The most common =causes= of kyphosis are Pott's disease, rachitis, occupation, general weakness, rheumatism and old age.

In Pott's disease, the posterior curve is characterized by a sharp angle, and by the spine being very rigid. This, taken in conjunction with the history and other symptoms should be sufficient to enable one to make a diagnosis. Radiographic examination should be made.

The condition of round shoulders, which in time produces marked kyphosis, is rarely a habit as it is usually termed. In nearly every case it indicates either a weakness of the back muscles or, what is more apt to be the cause, a strained posterior condition of the dorsal vertebræ, commonly of the lower dorsal region.

=Morbid Anatomy.=—In mild cases there is simply a relaxation of the ligaments of the vertebræ and a separation of the laminæ and spinous processes. In severe forms there may be absorption of the anterior portion of the intervertebral discs and the bodies of the vertebræ (Pott's disease).

=Lordosis.=—This may be a congenital condition, especially when occurring in the lumbar region. Anterior curves of the spine are generally found in the lumbar or cervical regions, but occasionally occur in the dorsal region, causing the spinal column to be more or less straight, and thus weakening the individual. This curve is commonly compensatory to kyphosis, hip-joint disease and congenital dislocations of the hip.

=Treatment= of =Spinal Curvatures=.—The treatment of pathological curves of the spinal column, by osteopathic methods, has been highly satisfactory to both osteopath and patient. The success of the osteopath in these cases has been due to his comprehensive and exact knowledge of each vertebra, and of the spinal column in general. He recognizes curvatures that the ordinary practitioner, and it is safe to say the orthopaedic specialist, would not even notice or recognize. On account of the highly developed sense of touch of the osteopath, he is capable of detecting the slightest deviation of one vertebra from another, and of the spine in general from the normal. Thus by the uniqueness and peculiarity of his work he is capable, not only of discovering a curvature, but also of reducing a curve when found.

The work consists of, first, relaxing any muscles that may have become rigid over the seat of the curve. Then follows a treatment to each vertebra involved, by attempting to replace it, and treatment to the curve in general by springing it toward its normal position. At each treatment effort should be made to accomplish something toward correcting the spine; too many treatments are given in a "general" way, and being unspecialized amount to nothing. One must become familiar with the exact location of each vertebra involved, to attempt a correction of a curvature intelligently. Upon this one point it is impossible to speak too strongly, for a great many treatments have been wasted and improvement of cases retarded by not paying enough attention to the details of the diagnosis, either from pure slothfulness or from an imperfect conception of osteopathy. Corrective exercises are always of value in addition to treatment.

These remarks refer to incipient and certain moderate curvatures. In other cases radical measures (Abbott) should be employed if age and conditions permit. Remember, however, that the practitioner in his daily work of adjusting the many combinations of rotation and sidebending lesions corrects innumerable actual and impending curves.

=Lateral curvature= in the dorsal region is undoubtedly the hardest to correct on account of the ribs, which complicate the condition. A marked curve in the dorsal region is sure to be accompanied by a dislocation of the vertebral end of one or more ribs. Treat each distinct lesion separately, follow by general stretching, replacing and molding of the tissues. A good method to stretch tissues and adjust a moderate lateral curve is to utilize the swing, or in lieu of this have the patient stand just at arm's length from the wall with concave side toward the wall with straight arm at right angles and palm resting against the wall. Stand in front of patient whose feet are firmly on the floor and reach around with both hands upon the spine. As the patient sidebends toward the wall it tends to correct the deformity, so if the operator coordinates his adjustment with that lateral movement of the patient, precise fulcra can be obtained and a certain, definite correction secured. The significance rests with the stretching of tissues and the definite fulcra obtained, thereby securing a maximum sidebending and rotation toward correction.

The =dislocation= of an =innominate= sometimes complicates matters, but is a simple point to remedy, and should not be overlooked.

The correction of a curvature presents a special study to the osteopath, whether it be scoliosis, kyphosis or lordosis, and special rules cannot be laid down for treatment. Cases of rare occurrence are what might be termed "symmetrical" curves; i. e., no vertebra presents separately a marked lesion, the column on the whole being simply bowed. Such cases can be treated by springing back the spinal column, and by the use of methodical exercises. Unfortunately most curvatures are characterized by various lesions between the vertebræ, and thus each lesion requires special work.

In simple curves the use of braces, jackets, and the various mechanical appliances are of very little use to the osteopath, in fact, more harmful on the whole, than beneficial. Naturally they would apply to a "symmetrical" curve, or where the patient is too weak to sit or walk, but they can be of very little use to the average patient, in place of correct osteopathic treatment. Mechanical appliances confine the movements of the patient, interfere with the development of the muscles, and impinge to a greater or less extent the spinal nerves. Due attention to hygienic surroundings and diet are certainly of aid. Proper exercises and occupation for the sufferer should be advised. Special care should be taken in examining (radiographic) for infectious lesions (arthritis).

=Straight Spine= is a term used particularly by osteopaths for a condition seldom recognized by orthopedic surgeons. The following is from H. W. Forbes[40]: Straight spine is "a departure from the normal in the conformation of the chest; characterized anatomically by bilateral diminution in size, decrease in the antero-posterior diameter, relative increase in the transverse diameter and flattening of the anterior and posterior walls; characterized clinically by diminution of respiratory capacity, lowered lung and heart resistance, impaired general nutrition and predisposition to neurosis.

"Of the many possible manipulations that may be used to lift and overcome the morbid bend of the ribs I will attempt the description of but one.

"Relax the musculature of the back and chest. Rotate, flex and extend the dorsal spine. Examine all the ribs on each side and loosen any that do not move freely. Having done this, the patient is prepared for the specific treatment. Have the patient sit on a stool and lean forward on a table. Have him separate the elbows, flex the forearms, place one hand over the other and his forehead on the hands. Tell him to relax all the muscles of the shoulders and arms and to breathe deeply without using the muscles. After a few trials he is able to fully expand his chest without contracting the muscles connecting the upper extremity with the trunk. The physician then takes a position at side (either side) of the patient and places the weight of his trunk on the ribs of the side he is on, a little external to their angles. He passes his arms around the patient's body; the arms passing across the front of the chest are carried around far enough to allow the hand to be placed on the ribs just external to their angles. The other hand is placed on the top of this one. In this position the physician's body on one side, and his hands on the opposite, occupy similar positions. The patient is now told to inspire deeply and at the same time to relax the shoulder muscles, as before instructed. As the chest expands drop the weight of the trunk on one side and make pressure forward (forward meaning toward the anterior surface of patient's body) with the hands on the other side. This lifts the ribs to a greater extent than the patient unassisted could lift them. At the end of inspiration and during the first third of expiration the chest is compressed laterally. The compressing force, if applied correctly, will fix the ribs in a position of less obliquity and will also correct the increased lateral bending of them. The dorsal spine becomes more convex posteriorly at the moment of lateral compression of the thorax, if correctly made. Great force should not be used at the beginning. Repeat the manipulation five to twenty times each treatment. Give treatment three times a week. A similar movement may be given on the table.

“The greater number of flat chests in patients under thirty years of age may be corrected. If the patient is above thirty, although complete correction may not always be accomplished, the results are satisfactory. Two to six months treatment is required.”

=A “typhoid spine”= comes as a sequel to typhoid fever. There is constant pain, tenderness along the lumbar region and rise of temperature. The pain is generally increased when the spine is moved forward or sidewise. Such a condition is clearly understood by the osteopath. There are always found distinct vertebral lesions along the region that is tender on pressure. In fact these very lesions may have been the predisposing cause of the attack of typhoid fever. The treatment is rest and the indicated manipulation to correct the derangements. It is of great interest to note that where the typhoid patient is treated osteopathically the condition just described seldom results. Observations by C. M. T. Hulett confirm this statement.

The =Neurotic Spine= may be the result of injury but the subject is usually of a nervous, neurasthenic type. It occurs from the age of puberty to adult, much more often in females than males.

The patient has dull pain in the back of the neck or in the lumbar or sacral region, complains of a constant tired feeling and often of a sharp neuralgic pain in certain parts of the spine. Generally there is a drooping posture in the upper dorsal with shoulders thrown forward, which is a sign of weakness. There is extreme tenderness along the spine and usually the pain is confined to the sensitive places.

Treatment consists of a constitutional toning up, and increasing muscular strength through judicious exercise. The posterior curve may be pushed toward the median line by laying the patient on the face; also with the knee in the back and the flat of both hands on the sternal ends raise the ribs; or by the arms making use of the pectoral muscles accomplish the same result. Deep breathing is also effective. Relief can usually be given and a cure will depend upon the patient’s general condition.

The =Hysterical Spine= is usually considered the same as the neurotic spine, but there are many cases which have the sensitive spine without being hysterical. There is more deformity usually present, particularly in the lumbar region. Probably there will be a history of some injury.

The treatment is to correct the curvature and build up the general health. These conditions are stubborn and progress is slow. In both the neurotic and hysterical spines the ligaments of certain areas will be found atonied and relaxed. This is especially noticed upon attempting to spring a group of vertebræ when all of a sudden the section relaxes. In either of these spines the lesions will irritate or obstruct nervous courses, produce venous stagnation or arterial starvation, and disturb lymph channels. H. F. Goetz has observed that in functional nervous diseases the dorsal spine is flat, while in visceral displacement the dorso-lumbar spine is posterior.

The =Spine of the Aged= wherein is found stooped shoulders and a rigid spinal structure, can be distinctly improved by slow, cautious traction. This tones weakened muscles, releases contractures, separates the compressed intervertebral discs, and definitely tones the viscera. Careful work is imperative.

[40] Journal of the American Osteopathic Association.

POTT’S DISEASE

An article on Pott’s disease does not really come within the province of a practice of medicine. Still it will be acceptable to the practitioners and students of osteopathy, as one of the objects of osteopathic work is to improve, not only medical and obstetrical practice, but also surgical practice, and besides the osteopath will have many cases of spondylitis to treat. “Pott’s disease, or caries of vertebral bodies, was first described by Percival Pott in 1779. It consists of a destructive ostitis affecting the spongy tissue of one or more of the bodies of the vertebræ. The ostitis is tuberculous, and is similar in character to tubercular ostitis seen in the epiphysis of the long bones. Owing to the superincumbent weight of the head and shoulders pressing upon the carious vertebral bodies, the spine and trunk become peculiarly and characteristically distorted. The morbid process is limited, as a rule, to the bodies; the transverse, articular, and spinous processes are rarely primarily affected.” (Park).

The first consideration in the =treatment= of Pott’s disease is rest. If the disease is a progressive one, rest in bed in the recumbent position is necessary. Naturally, the object of the treatment is to secure resolution of the tubercular ostitis as soon as possible. To do this, careful manipulative treatment should be applied to the diseased vertebræ. The treatment must not be harsh, for there

would be danger of greater irritation to the parts, and possibly infected particles from the destroyed tissue might gain entrance to the vascular system. The osteopath must be extremely careful how he manipulates the spinal column in Pott's disease. The object of the manipulation is not primarily to overcome the deformity, as some may think such an act possible, but to separate the vertebræ enough to allow a freedom of the circulation, and to remove impingements of the nerve tissue. It is impossible to overcome the deformity to any extent when part of the body of the vertebra is destroyed; but if one could treat the case at the incipiency, most probably deformity would be prevented. There is another danger in treating cases too severely, and that is causing exhaustion of the patient. Treat the spinal column not only to separate each articulation slightly, but to carefully crowd the diseased vertebræ toward their normal position. When the disease is in the dorsal region, considerable attention has to be paid to the ribs, as they are invariably involved when the spinal curvature is great. Hence it is necessary to treat each rib separately, and try to correct them at least, and remove any obstruction to nerve fibres or vessels that may be found. One of the strongest arguments against the indiscriminate use of braces, jackets and various mechanical appliances in spinal deformities, is that they tend to straighten the spine, by simply crowding the vertebræ and ribs as a whole into place, besides interfering with the cutaneous circulation. The osteopath should realize that each vertebra and rib has to receive special treatment, in order to correct the spinal column, and that mechanically exerting pressure upon all the vertebræ at one time tends to lock the vertebræ and ribs all the more securely. It is like trying to correct a certain subdislocation of the cervical vertebræ by pulling and twisting the neck instead of applying specific treatment—the lesion is all the more firmly fastened. Young, in his Surgery, makes this observation: "Like chronic abscess or chronic bone disease, this affection has its origin in the fact that the tissues of the anterior parts of the bodies of the vertebræ have been partly deprived of their nutrition because of luxated ribs or subluxated or twisted vertebræ."

After the tissue destruction has been limited, and the deformity corrected as much as can be, an ankylosis should be secured if possible. Promotion of ankylosis depends altogether upon the preceding treatment—rest and an improved nutrition of the parts. A truss or brace, if correctly applied, is often beneficial in such cases. The treatment of spinal abscesses is entirely in accordance with surgical treatment.

In all cases the general health of the patient has to be well taken care of. The osteopath must not be over zealous for quick results. It takes many months to perform a cure; however, there is always a tendency toward a cure. Treatment of the spinal muscles and of the limbs, and pure air, sunlight, massage and good food are very necessary.

SPRAINS AND FRACTURES

SPRAINS

The osteopath is often called upon to treat sprains of various sections of the body as well as to relieve after effects of fractures and restore function to the part. The osteopathic treatment is very effectual; therefore, an outline of the purpose and method is given.

Sprain is defined by Dorland as "the wrenching of a joint with partial rupture or other injury of its attachments, and without luxation of bones." From an osteopathic viewpoint the above definition is not fully explanatory, for there is in most cases a partial luxation of the bones. The most common cause of a sprain becoming chronic is the presence of partial bony displacements. Rupture of tissues may be the cause of a chronic state but is not nearly so frequent as the bony dislocation. In most sprains, the wrenching causes a displacement of the bony tissues, which may or may not return to normal position and relation. The function of the muscles is not primarily to hold the bones in place; this is left to the ligaments, so when a wrench of a joint is so severe as to cause rupture of muscles or tearing of ligaments, partial luxation of the bones is almost certain to follow; and even where such damage does not occur a change in the relation of the bones is a frequent occurrence.

Unless a sprain can be seen very early it may be difficult to detect just what has happened; whether it rests with a rupture of the areolar and connective tissues, a displaced cartilage, tendon, or bone, a torn ligament, or ruptured muscle. Hemorrhage and swelling take place so rapidly that no time should be lost in critically examining the joint. When in doubt as to the structural disturbances, particularly in acute cases if there is a possibility of a fracture, and in chronic cases any supposition that tubercular involvement is present, have a radiographic examination.

There is comparatively little to be found in medical literature relative to the =pathology= of sprains. Probably Moullin in his excellent monograph on Sprains has given as good an outline as can be found[41]. He says that "generally speaking, the tissues on one side of a joint are overstretched and torn; those on the other compressed and crushed together; but there is always so much twisting, and such a difference in the strength and power of resistance of various structures, that unless the part is examined with the

greatest care it is almost impossible to say what actually has given way." Hemorrhage due to torn vessels is the cause of most of the swelling within the first few hours. Later on, there is considerable lymph mixed with the blood. There is not only extravasation of blood into the surrounding tissues but also into the synovial wall and cavity. This causes considerable irritation and pain owing to the roughening of the membrane, and the joint becomes inflexible. And if the joint or any strained tissue is kept too long at rest the mass becomes organized and is the cause of much discomfort and annoyance.

Similar changes may occur in the bursæ due to the extravasated blood. Strong ligaments may be torn across, but not frequently. The tear is usually a separation from the bone. Occasionally interosseous ligaments, as for instance in the knee, may be injured.

The muscles may be severely torn, but more often they are "hurt by their own sudden and spasmodic effort at recovery than by anything else." In a few cases the tendons and muscles will be found bruised, lacerated, and dislocated.

The veins occasionally rupture and thus results more or less effusion, so that rigidity and edema may persist for a long time. The bones are very frequently damaged. This may be a simple bruising of the tissue but more often, as osteopathic diagnosis shows, there is partial displacement of the bony structure.

A point of great importance that every experienced osteopath will agree to is the following from Moullin: "Diseases of the spine, hip, and other joints in children may be due, in great measure, to some constitutional taint, though it is open to question whether the influence of this is not overrated; but it is quite certain that the immediate starting point in nine cases out of ten is some chance sprain, often so slight as scarcely to have been noticed at the time."

Before treating a sprain there are one or two points the osteopath should carefully note: first, that there is no complicative fracture; second, in children that there is not an epiphysial separation; and, third, note peculiarities of a constitutional character that would complicate matters. Whatever is done, always give the patient the benefit of the doubt.

If the patient can be seen early, before swelling has reached the maximum, many times a very quick cure can be secured. Do not at once put the part at rest and apply cold, but examine the sprain most carefully and thoroughly and readjust first of all any bony defects; then replace the softer tissues if displaced, and next relax contractions; follow this by light massage and passive movements to reduce and combat hemorrhage and swelling. This treatment alone in a fair percentage of cases will be all that is necessary provided frequent subsequent treatments of massage and passive movements are continued to reduce and counteract inflammation and to prevent rigidity and stiffness of the softer tissues. Where the osteopathic treatment is distinctly indicated is in the readjustive manipulation. This is the reason why the treatment is so efficacious, and the patient is cured in a fraction of the usual time, and few sprains result in complications and become chronic. In sprains that have become chronic there will be found almost invariably some osseous tissue slightly displaced. After correcting this, apply careful and thorough manipulation and massage and movements to break up adhesions, to remove effusions and extravasations, to relax muscles, and to promote normal circulation. Care should be taken that there are no displaced cartilages, ligaments, tendons, or muscles.

It is well to keep in mind that the osteopathic readjustive manipulation is not an exercise or movement, but definite, specific correction of the tissues anatomically. Do not treat the displacement by any general "pommelling," but apply the mechanical principles indicated as in any dislocation. This will mean much to the patient in more ways than one, and especially so should the sprain be so severe and complicated as to demand anesthesia for correction.

There is no objection to the employment of cold and heat; in fact, both are beneficial. Cold to prevent extravasation and swelling, and heat to remove and relieve the same, is a sound and practical method. But do not apply a wet bandage. Pouring cold water over the sprain is the best method; even better than immersing the part. An ice bag is another good way to apply cold. When the skin begins to look blanched and dull the maximum amount of benefit has been secured. Heat at the very first may be employed instead of cold, for it has a tendency to prevent bleeding and inflammation, but the temperature of the application must be hot as can be borne or else the desired effect will not be obtained. Later on to relieve pain and rigidity, and to relax the muscles so that a better circulation will be secured, moderate heat will be beneficial. Then the application of heat and cold alternately will be of service, employed as a douche for a tonic effect, when the part is weak, inactive, and powerless after the elapse of several days. It should always be remembered that the employment of heat and cold is only of temporary benefit, so if used too long opposite effects to those desired will result.

Bandaging the sprain may be helpful, but not always. Great care should be taken as to how pressure is applied. Bandaging from periphery toward the trunk, seeing that the bandage is smooth, and padding all depressions so that the bandage does not touch

bony prominences only, are necessary. Unless the bandage is applied so that an even pressure is secured, the material used not too warm, and the bandage attended to each day, the effectiveness will amount to but little.

Next, do not make the mistake of resting the injured joint too much. The function of a joint is movement, and it has been observed that prolonged rest of a healthy joint may result in rigidity, stiffness, and distension of the soft part, and even serious organic changes in the ligaments, synovial membrane, and cartilages have occurred. Consequently continued passive movements should be kept up from the inception of the injury, although it must not be carried to extremes so that inflammation, hemorrhage, or laceration will be aggravated. Moullin says: “As a rule, passive movement may be commenced from the second day with the certainty of preventing adhesions, and without the least fear.” Osteopathically, with due attention to readjustive manipulation, and care as to correct position and rest, passive motion will be allowable usually from the first day.

There is much corroborative evidence in current medical literature that bears in a general way upon part of the foregoing. The International Text Book of Surgery says: “Massage should begin early, in order to avoid, as far as possible, weakness of the muscles, and to ensure security to the position of the joints by the retention of a proper tone in them;” besides, early movement tends to reduce the effusion into the tendon sheaths around the articulation, which in some cases, particularly the ankle and wrist, may be a very prominent feature. The Reference Hand Book of the Medical Sciences voices the same opinion; and Mumford is referred to as follows: “Immobilization for more than a few days, as under the older methods, is objectionable because adhesions are apt to form, thus causing impairment of function, and because when there is a =tubercular taint=, proper conditions for a localized tuberculosis are established.” Among other statements Holder Sneve in the Journal of the American Medical Association of June 1, 1901, says: “Immobilization of muscles is not rest. On the contrary, in all sprains the muscles should have passive exercise the first few hours and days, and active exercise after that. In the majority of cases active exercise should be instituted from the beginning. The plaster cast should not be used at all, even in cases where we have a fracture, unless it be impossible to maintain a proper position of the joint.”[42]

Again quotation is made from Moullin. These quotations are taken from the chapters on Manipulation and Massage. It will be observed he makes a distinction between the two methods. And the osteopath should carefully keep in mind not only the difference between the two, but beyond these the more fundamental treatment, readjustment. The characteristic feature of osteopathy is anatomical readjustment, and this in sprains should be supplemented by massage (superficial work), and also manipulation (deep and more or less forcible work) in order to remove stiffness, rigidity, and fibrous ankylosis.

The following is relative to forcible manipulation: “Manipulation is much more useful than division; it can be employed for such a variety of purposes. In the early stages it prevents the occurrence of stiffness or the formation of adhesions. Later, when the swelling and heat have disappeared, it is no less successful in restoring freedom and ease of movement, and afterward, when all mechanical obstructions have been cleared away by its use, it is one of the most effectual methods known for bringing back the circulation and nutrition of the part, and giving again to the muscles and nerves the energy which has so long been wanting....

“To carry this out effectively two things are needed beyond all others. The one is a sense of touch so delicate that it can appreciate the least resistance or irregularity of movement; the other an accurate knowledge, not merely of the ordinary anatomy of the part, but of the different degrees of tension that fall on the ligaments in every position of the limb.

“Each joint requires a different kind of manipulation according to its construction....

“There should be no jerking. The movements must be vigorous and forcible, but perfectly smooth; and they must be carried out thoroughly, the joint being moved to its full extent in all directions that are natural to it. Each kind of action should be combined successively with the rest, one by one, so that the tension may fall in turn upon all the different parts of the capsule.

“Movements which are especially restricted or painful, of course require most attention, but the others, though they may not be affected to the same extent, are not to be neglected. It sometimes happens if these are dealt with first, that a considerable proportion of the main obstruction is cleared away, as it were, by side attacks, so that when its turn comes it yields more readily than it otherwise would.

“Recent slight adhesions give away at once without a sound, though the sensation is generally conveyed to the hand. When they are older the noise may be as loud and clear as when a bone is broken....

“The after treatment of these cases (cases where there has been tearing and breaking of adhesions) should be in all respects the same as that of a recent sprain, only if passive motion at an early date is advisable to prevent the occurrence of stiffness in the one,

it is absolutely necessary in the other."

The following pertains to massage of sprains: "Massage, in the strict sense of the term, is a great deal more efficacious, especially with older sprains. Its action is not limited to the skin and superficial structures. These undergo immense changes, it is true; they become softer and finer while under manipulation; their strength and elasticity increase, the extreme tenderness diminishes, and the natural appearance and texture return. The surface loses its dry, harsh character and becomes warm and moist again; the livid bluish color gives away to a brighter hue, and the deeper layers of fibrous tissue yield and stretch, so that the hide-bound, shrunken condition that is often present after long disuse gradually passes off. But the good effect is not by any means limited to, or even most conspicuously shown by, this. When properly carried out, massage exerts a simultaneous influence on muscles, nerves, and vessels; in fact, on all the tissues within its reach.

"The circulation is the first thing to feel its power. It has already been explained how, after prolonged rest, the blood, as it were, lies almost stagnant in the tissues, slowly circulating through them, and neither giving them sufficient for their nutrition, nor removing from them the waste products of their action. This is changed at once. The life of the part is quickened. The veins and absorbents are emptied first, and the fluid they contain driven out into the heart, which fills more rapidly, and contracts more vigorously and firmly. Then the pressure falls in the smaller vessels, and the tiny irregular spaces, full of lymph, which extend in all directions through the tissues. These, in their turn, are compressed and mechanically emptied, their contents being driven on into the empty vessels, from which any backward flow is prevented by the valves. The circulation becomes more rapid; nutrition is carried on with greater energy, and the actual amount of the blood in the tissues at any one time so much increased that they become full and soft to the touch and regain the even and rounded contour of active health....

"It is most essential to commence as gradually and as gently as possible, working on the deeper tissues only after the more superficial ones have become thoroughly accustomed, and have been unloaded of their surplus fluid. The skin, the soft subcutaneous tissue, the muscles, and the deeper layers, must all be worked in turn. Nor should the manipulation be confined to the injured part. In a sprain of any standing, the whole of the limb is affected more or less. It is usually better to devote attention first to the parts nearer the trunk than to deal with those around the injured area, and only afterward, when the circulation is thoroughly reestablished, to manipulate the joint itself.

"The tendency is to make the sittings last too long. Deep manipulation itself rarely requires more than =five minutes=; but in dealing with a recent injury it may be advisable to spend a longer time than this over the friction and other preparatory measures, so that a quarter of an hour soon passes by. When the tenderness is very great, and the amount of swelling excessive, much longer than this may be necessary, but short, frequently repeated sittings are of greater benefit than one long one. A skillful operator, too, will often effect more in a few minutes than an ordinary rubber will in as many sittings."

A summary of the general treatments of sprains would be as follows:

1. Readjustment of parts and removal of obstructions. Osteopathy is especially adapted in these cases, for two of the primal therapeutic factors in all cases from an osteopathic viewpoint are to readjust the anatomical and to remove obstructions. One should constantly keep in mind, "a temporary displacement followed immediately by a return to place, constitutes a sprain." The osteopath often finds that a perfect returning does not take place, and even remote lesions may affect a joint.

2. Manipulation, and massage of soft tissues, to restore circulation and to prevent and remove debris from rupture of vessels and inflammatory products.

3. The employment of cold, heat and pressure, and a certain amount of rest.

4. Anatomical readjustment and manipulation in chronic cases to break up adhesions, remove exudates, overcome the organized products of inflammation, and cure synovitis.

5. Movements both passive and active to stimulate and exercise functions of the joint.

=The Spinal Column.=—The osteopath is especially cognizant of the fact that many sprains occur to the spinal column. These may affect a single joint, or more or less of a section may be involved. The bones, ligaments, tendons, muscles, or spinal cord may be found injured. Even distant organs, through involvement of the circulation to the cord, or through irritation or impingement of spinal nerves and sympathetics, are frequently disordered. It is not necessary to go into detailed description, for the points bearing upon this will be found under Osteopathic Diagnosis, Etiology, and Technique, and the general description will, also, apply.

Readjustment, strapping, heat, massage, manipulation, ironing, stretching of muscles, fomentation, etc., have their place. There is no doubt that sprains, strains, and blows to the spinal column are the cause of many spinal disorders and consequent visceral disturbances.

=The Ribs.=—Sprains of the vertebral ends frequently occur, resulting in a partial luxation, stretching of ligaments, contraction of muscles, and exudative formation in the joint structures, which often is the cause of irritation to the sympathetic nerves. The costal cartilages are frequently strained, and may so irritate the intercostal nerve as to cause considerable pain both locally and reflexly. The treatment is essentially one of replacement, and relaxation of the softer tissues. Adhesive strips to limit movement due to respiration may be helpful.

=The Innominata.=—Sprains of the innominata are also commonly met with. Besides being a source of discomfort to the patient they are an important cause of pelvic disorders and leg affections. Partial displacements are the rule, the correction of which gives quick relief. Where there is considerable spasm of muscles, examine carefully the lumbar alignment. In chronic cases fibrosis of muscles and adhesions may complicate matters.

=The Hip Joint.=—Sprains involving the hip joint may be readily corrected, and again may be the exciting cause of serious involvement. Previous tubercular disease can be aggravated in this manner, or syphilitic changes in the joint disturbed. Care should be taken that there are no complicating displacements of the innominata or irritations to the spinal nerves. Possibly the hip may be so strained as to cause a twist of the femur in the socket and thus simulate a partial dislocation; this, in fact, would probably be termed a partial dislocation. Strain of one set of muscles about the hip joint is somewhat rare, and spinal lesions may disturb the innervation to one set of muscles. In cases of =intracapsular fracture= considerable can be done by careful massage and manipulation after union has taken place, to secure greater freedom of movement and strength of the limb. Likewise in =hip-joint disease=, after the disease is healed, massage and manipulation will be very beneficial. Care must be taken if the treatment causes spasticity of the muscles; this shows the treatment is irritative and should be stopped until the spasticity has ceased. Where the limb is shortened from either hip-joint disease or intracapsular fracture apparent lengthening may be secured by careful abductive and hyperextensive stretching.

=The Knee.=—The knee is the most complicated joint, and sprains are apt to be very serious. The usual treatment for sprains is employed. Occasionally the semilunar cartilages are displaced and may be a source of difficulty in diagnosis; likewise injuries to the patellar tendon and lateral ligaments. Another joint frequently overlooked is the innominate. In a number of knee cases that terminate in chronic synovitis there will be found a displacement of the innominate that is preventing recovery. A villous synovitis may arise in strains from faulty posture, especially in the obese. Injury to the hip-joint, also, may cause strain or irritation at the knee. Occasionally tender points about the knee, especially at the inner side, are due to irritation at the hip, or possibly from the spine. Referred pain of the knee joint is of frequent occurrence.

=The Ankle and Foot.=—The ankle is often sprained. One should examine carefully for a possible fracture of the malleolus, and for fracture of the tibia. There may be a dislocation of the fibula, also a separating of the tibia and fibula at the ankle. The common bony displacement takes place between the astragalus and os calcis. Then the cuboid is frequently displaced, and occasionally the navicular. The treatment should first of all be directed to correction of the osseous lesions. The arch of the instep may be weakened from the ligamentous strain and be an immediate step in the production of =flat foot=. Teall is of the opinion that lumbar and innominate displacement are common predisposing causes. Faulty position of the foot in walking may be an underlying factor.

=Bunions= result from a malposition of the joint. =Morton’s disease= due to a pinching of the metatarsal nerve will often yield to osteopathic treatment alone. There is generally displacement of the metatarsal bone. A pad worn directly under the painful point will be of benefit. In many of the local neuralgias, some anatomical displacement will be found as the exciting cause. =Hammer-toe= if not complicated with gout, rheumatism, etc., will yield to treatment if kept at persistently, otherwise surgical interference will be necessary.

Likewise various deformities of the foot and resulting neuralgias may be traced to local sprains, ill-fitting shoes, or anatomical maladjustments higher up of such a character as to affect the pedal circulation.

Flat Foot

Flat foot or weak foot is one of the common disorders that the osteopath is constantly called upon to treat. In the first place the patient should be taught to walk correctly. The feet should be parallel in walking so that the weakened muscles may be developed

and strengthened. This will be difficult at first, but recovery depends upon this important point. In addition to this, special exercises, like turning the toes under and tip toe exercises, should be persisted in for a few minutes two or three times daily. Upon the other hand, do not overdo the exercises but always carry them to a point of fatigue. These two features, walking correctly and exercising, are essential complementary measures to the adjusting treatment. In conjunction with the above, the Scotch douche at the end of the day will prove of considerable benefit.

In the technique work, first make certain that there are no innominate or spinal lesions that bear upon the circulation and innervation of the feet. Then frequently faulty walking is due to these lesions.

In recent cases, simply remolding the arches of the foot will be all that is necessary, providing correct walking and foot exercising is maintained. But in the more chronic cases considerable adjusting and remolding of the tissues, bones, ligaments, muscles and fascia, are demanded. Perfect apposition between the astragalus and navicular bones, the highest point of the longitudinal arch, should be first secured. Attention should also be given the other articulating structures down to the metatarsal bones. This reestablishes the arch and overcomes the everted tendency. Considerable repeated force is often demanded to release the fibrotic tissues, but it is the important part of this technique.

With the patient on the table, supine, place your thumb firmly at the articulation of the navicular and astragalus. Then with the other hand around the metatarsals to be used as a lever in extending, rotating and inverting the foot with the fulcrum at the thumb of the first hand, spring, thrust and adjust the arch. This requires considerable strength and exactness of application. The tissues must give freely before the result can be secured. This is often painful to the patient but should be continued and repeated to the furthest point of motion until recovery is complete. Treat as often as the condition permits. Substituting the crotch of the thumb and forefinger or the knee for the thumb will give added advantage. Follow this with thorough springing of the plantar tissues by thumb and fingers.

If this is kept up with suitable exercises and correct walking, and proper shoes (Munson last), excellent results will be obtained in the great majority of cases. Same pair of shoes should not be worn two days in succession.

Many times the anterior arch is involved, jointly or separately. Persistent adjusting and remolding of the arch tissues will secure satisfactory results unless the bones are markedly deformed and the weight of the body is relatively too great. In this disorder, aside from paying special attention to the metatarsal articulations, the great toe requires a particular technique. For this grasp the toe firmly, exert traction until the tissue gives slightly and rotate it inward, toward the median line of the body, on its longitudinal axis. Have the patient frequently turn the toes under, or attempt to do it until the exercise can be easily accomplished.

Do not employ arch supporters except in hopeless cases. They simply splint the foot and thus further weaken the foot muscles. If the above methods are persistently followed to the point of actual adjustment, accompanied by releasing of fibrous tissue and actual strengthening of muscles through exercise, a very large percentage of cases will recover. In a few cases adhesive strips will be of benefit.

=The Shoulder.=—Exclusive of muscular and other strains there may be a partial dislocation. In these cases the acromial end of the clavicle is frequently dislocated, and owing to a general lack of muscular tone may be very hard to keep in place. The lower and inner part of the capsule is often affected, so that freedom of function is lacking and there is considerable pain. This is due to the thinness of the capsule and the large amount of soft tissue, so that when the arm hangs at the side the tissue is thrown into folds; and being very vascular is easily injured, so that the vascular lymph readily organizes and the part becomes stiff and unyielding. It requires patient, laborious treatment to break up and absorb this fibrous tissue. Then the long tendon of the biceps in some shoulder sprains is dislocated, but rarely. In shoulder injuries, examine also, the upper ribs.

=The Elbow.=—The elbow is another complicated joint. One should be careful that there is no fracture, and in children that there is not =epiphysial separation=. Extending, flexing, pronating and supinating the arm will aid much in the diagnosis. Examine well the rotation of the radius at the elbow joint, and be positive that the olecranon process drops normally into its fossa at the end of the humerus.

=The Wrist and Hand.=—The wrist is another joint commonly sprained. Here, also, care should be taken that a fracture does not exist. Colle’s fracture is frequent. The bursal and tendon sheaths are usually markedly involved. The scaphoid and semilunar are apt to be displaced; also, the os magnum and the unciform.

Sprains of the =fingers= are often met with. Outside of strains to the muscles, ligaments, and other tissues the joint is apt to be somewhat impacted. Traction will correct the latter. Care should be taken that a fracture is not present. =Dupuytren's contraction= occurs from sprains or injuries, as the result of contraction of the fascia. The ring and index fingers are members usually affected. In some cases the affection will be found in both hands (symmetrical), and a spinal lesion will be the predisposing factor. Treatment every day, by straightening the fingers and stretching the tissue will at least retard the deformity, but in a number of cases surgery will have to be resorted to.

A =ganglion= or "weeping sinew" is a swelling in connection with the tendon sheath. It presents a round, firm outline, usually upon the back of the wrist. There is generally found a displacement of one or more of the wrist bones. If treatment of the joint and tendon sheath does not remove the ganglion, surgery may be utilized. =Trigger-finger= is a rare disorder. There is usually a history of local strain, which probably resulted in some thickening of the tendon. Manipulation and passive motion if continued will generally give relief.

Fractures

Immobilization and rest have been the paramount points with most physicians in the treatment of fractures and sprains. They have claimed that a sprain should be manipulated but rarely, much less a fractured bone. Rest, quiet, and fixation of an injured joint or bone have been rules that should not be violated under any consideration. In cases of sprain the great cry has been to let the joint alone for fear of spreading a possible =tubercular infection=. It is well to recall Mumford's statement that if immobilization is too long continued, should there be a tubercular taint, proper conditions for a localized tuberculosis is established. And still a word of caution here, that an osteopath should not be over zealous and should carefully weigh all possible factors, both local and constitutional, may not be amiss. In previous tubercular, syphilitic, and other diseased states discretion should be employed.

Reducing rest and immobilization to a minimum means much to the patient, not only in the loss of valuable time but in annoying and serious after effects. Many cases of sprains and fractures come to the osteopath. In sprains that have become chronic through too much rest of the part and improper treatment, almost invariably there is found displacements of bone and adhesions that should never have existed; then has followed organized exudates and chronic synovitis. In fractures and even in complete dislocations the osteopath continually observes that too much rest has been given the part, resulting in unnecessary adhesions, contractions, atrophy of muscles, and impairment of function. Treatment almost always cures the condition, or at least materially relieves. How much better if the proper treatment had been first instituted and thus a large percentage of cases prevented from becoming chronic.

Of particular interest to the osteopath is the paper prepared by Eisendrath on "Early Massage and Movements in the Treatment of Fractures and Sprains," and the discussion that followed before the Chicago Medical Society. The Illinois Medical Journal, December, 1903, contains a report.

Eisendrath said in part: "The former routine of immobilizing all fractures and the adjacent joints for a period of four to six weeks must, I feel, be subject to slight modification in the light of recent experience, and it shall be the aim of this paper to show what these changes are. When we are called to a case of fracture, it should be one's first duty after its reduction to consider how can I best aid the patient in recovering the usefulness of his or her limbs? Can we shorten the long convalescence with its resultant loss of valuable time and earning capacity? How can we most rapidly restore to the limb its normal joint functions and prevent an atrophy of muscles and an ankylosis which will require many months to overcome?...

"The use of massage and of active and passive movements in the treatment of fractures and of severe sprains has been gradually gaining in the number of its advocates through the writings of Lucas-Championniere of Paris. We owe him a great debt for calling the attention of the profession to the employment of these methods in order to prevent atrophy and ankylosis as well as to promote healing....

"Before taking up my subject in detail permit me to recall a few salient points in the surgical pathology of fracture. Soon after the injury the blood clot around and between the ends of the fragments is absorbed and replaced by a jelly-like mass of young connective tissue cells called the callus. It corresponds to the solder which the plumber places over the ends of two pipes he desires to join. Bone begins to form at the periphery of the callus about the tenth day and advances toward the center rapidly, forming a ring of bone around the ends of the fragments so that by the end of the third week there is but slight abnormal motion at the point of fracture (exception to this is the femur). This entirely disappears by the end of the fourth week, especially in young people, and the union is firm. In the case of the femur it requires six or eight weeks. The greater the displacement of the ends of the fragment, the larger the callus and the slower the healing of the fracture.

“During these changes (callus formation) the muscles which supply the immobilized joints atrophy and the circulation in the skin and neighboring tissues is sluggish, resulting in swelling, etc., of the limb. The enforced rest causes more or less fluid to accumulate in the tendon sheaths and joints. This becomes organized and results in fibrous ankylosis of the joints and great impediment to the free action of the tendons within their sheaths. It is this atrophy, fibrous ankylosis and tenovaginitis which interfere with the restoration of the normal functions of the limb....

“Can we decrease the amount of wasting of muscles and control the stiffness of joints and tendons after fractures?

“It is the belief of the writer, based on a large experience, that the earlier use of massage, active and passive motions, will to a great extent eliminate the above conditions, which retard convalescence and in some cases cause permanent disability.

“Massage of an injured limb increases the amount of blood supplied to it, promotes the absorption of the swelling and prevents atrophy of muscles. In the case of a joint injury the exudate rapidly disappears and the articular surfaces can be again approximated so that movement is facilitated. By the cautious use of active and passive movements, either with or without the aid of apparatus, the normal functions of a joint can be rapidly restored....

“The active and passive movements of the limbs can be carried out immediately after the massage, but should only be permitted for a period of =five minutes= at first and the time then gradually increased. When a severe sprain, say the elbow or ankle, is first massaged, the pain seems to be almost unbearable, but this discomfort as well as the swelling rapidly disappears, and it is surprising to those who have never applied this treatment how quickly the normal function of the joint reappears. The same applies to the synovitis which accompanies fractures in close proximity or even into joints.”

The relief given these cases by massage, movements and manipulations by the osteopath is a daily experience, and results to him are not surprising. Then in addition to what the surgeon would do, the osteopath applies his principles of careful detail readjustment.

Eisendrath continues his paper by referring to the principal varieties of fractures and giving the treatment for each. He says that if correct treatment is carried out with proper massage and movements in fractures of one or both bones of the leg, the patient will be at work in six or seven weeks instead of three or four months, that in Colle’s fracture some surgeons do not employ a splint, and that in fractures of the olecranon, massage from the first week on is of the greatest use. This part is very interesting but space forbids giving it.

He then concludes his article with citation of several very interesting cases of fractures and severe sprains. These cases are exceptionally interesting to the osteopath, but still the same good treatment and results are duplicated every day in the osteopathic school.

The doctor’s contraindications to the use of early massage in fractures or sprains are the following:

“1. Tendency to displacement of fragments in oblique fractures. Under such conditions it is best not to begin either massage or movements until the union is firm (fourth to fifth week).

“2. In compound fractures until the wound is healed.

“3. Whenever the condition of the skin is such as to permit of infection; for example, the presence of blebs, or extensive abrasions.

“4. The presence of fragments which project but do not penetrate the skin.”

His conclusions are:

“1. Massage, active and passive motions prevent atrophy of muscles, tenovaginitis and ankylosis so frequently accompanying and following fractures, especially those close to the shoulder, elbow, wrist, knee and ankle joints.

“2. They give far better results than complete immobilization in the majority of fractures.”

In the discussion that followed Henrotin said that for some time, “I have never put a restraining apparatus of any kind, nor have I used any lotions on any sprain, no matter how severe....

“It has taken many years to bring this subject before the profession. It is a method that is absolutely effective as regards sprains and some forms of fractures. I have treated several hundred such cases with the greatest success.” He also said that, “In treating

an inflamed joint it is improper to use a restraining apparatus of any kind. I consider that the plaster cast is the bane of all inflamed joints unless there is a =specific form of infection=, a traumatic condition." Neither does he believe that an inflamed joint should be put at rest. He says the patient is a good judge as to the amount of quiet the joint needs. He has treated Colle's fractures and fractured clavicles without bandages or apparatus.

To sum up, the osteopathic procedure in the treatment of fractures would be as follows:

1. Immobilization in those cases especially demanding it, from the character of the fracture, until formation assures solid and firm union.

2. Manipulation and massage and movements of parts at an early period, compatible with the above, to render soft tissues pliable, to remove stiffness and adhesions, to restore a normal circulation, and to exercise and function the parts.

3. In cases of laceration of soft tissues, abrasions, etc., great care should be taken so as not to infect the parts.

4. Great care should be taken where fracture is compound, and where fragments exist.

5. In all cases, both acute and chronic, critically examine for slight anatomical deviations locally and remotely.

In dislocations the fundamentals of the above are applicable. Do not let chronic stiffness, or rigidity, adhesions, or synovitis supervene if possible to prevent.

An important consideration in all cases of sprains, fractures, and dislocations that become chronic is the probable effect upon dependent tissues by way of nerve impairment and vascular obstruction; for examples, the sprained back may readily impair organic life, the fractured elbow prevent use of the arm, the injured leg predispose to flat foot. (See J. B. Littlejohn—Osteopathic Surgery, including Treatment of Fractures, Journal of the American Osteopathic Association, Nov., 1905.)

POSTURAL DEFECTS

A postural defect is any abnormal position, congenital or acquired, of the body, assumed in sitting, standing or walking. This leads to a symmetrical development, causes structural changes, and as a sequel, disturbance of function and organic life results.

Defects in posture are of very common occurrence. A perfect posture, in fact, is somewhat rare. Considerable is being accomplished, especially of late years, by the laity through various physical methods and exercises to correct the many defects of position in sitting, standing and walking. The originators of the many so-termed systems of exercises have gone so far as to even advertise to cure various diseases of the body as well as attempting to improve the normal tissues and structure.

Exercises, undoubtedly, have their place, particularly in the life of those of sedentary habits. Most of us do not exercise enough, neither do we as a rule get enough fresh air and pure water. But there are many defects of the anatomical that mere gymnastics can not adjust. And there are still other defects that gymnastics may decidedly aggravate. In these cases the mechanism of the body has become so deranged and disturbed that nothing short of actual readjustment can be effective.

In the consideration of postural defects there are a few points that should be particularly emphasized. First, these defects may not only be the result of laziness or carelessness, but of more frequent occurrence is some previous strain or injury to the spinal column or other parts of the body framework. Some defect of position or symmetry of the body may easily follow as a result. Here gymnastic work may reduce the defect to a minimum, but rarely can the compensatory forces of nature entirely obliterate the structural disorder, unless assisted by actual, specific readjustment. Second, in the examination and treatment of the patient due attention should be given the symmetry and figure of the body as a whole so that relation of the part to the whole and _vice versa_ may be rightly proportioned. Remember that the spinal column is only one part of the body outline, thus one should consider the transverse section of the body in relation to the spinal column and not the spinal column alone. In a word, correction of postural defects implies both structural rearrangement and molding of the contour. Do not make the mistake, for example, when correcting a deformity that involves the chest, of paying attention to the spine alone, but take into consideration the thorax as a whole of which

the spine is only a part.

Round Shoulders

=Round Shoulders= are a defective posture with which everyone is familiar. How many children have escaped the parents' criticism to sit, stand, and walk erect? And not a few of the afflicted have not succeeded after persistently doing their best.

Round shoulders or stoop shoulders are commonly attributed to indifference. Probably a few cases are due simply to laziness and indifference, and others may be carelessness, and usually when they arrive at an age where pride of their physical demeanor and powers enters as a life factor, the child soon overcomes the postural weakness. With still others the correct, persistent physical training, as exemplified in military schools, will readjust the defect. But there is a class, and by far the largest, where round shoulders are a very real and active weakness of the physical body. And the weakness is not primarily in the shoulders as nearly everyone thinks. The stoop is a result. The origin is in the lower dorsal spinal column. Here will be found a posterior curvature that involves nearly the entire dorsal and lumbar areas. This is the real, the original cause of the larger number of round shoulders.

This backward curve of the spinal column, instead of the forward curve as it should normally be at the waist, obliterates the brace or truss of the spinal column that is so essential in maintaining an erect posture of the shoulders. It allows the individual to "fall into his stomach," to drop the shoulders, and as a consequence the chest cavity is depressed. The spine is one continuous backward bow, and when he does try to sit straight, and it is always with a constant effort, the normal, the physiological curves of the spine are not apparent.

First, then, there is a spinal weakness in the region of the innervation to the digestive organs. Indigestion of various forms is a common accompaniment. Second, there is lessened lung and heart capacity. The ribs are depressed, interfering with perfect aeration and elimination on the part of the lungs and with normal activity and tone of the heart muscles. Phthisis is predisposed. Is it any wonder the child's blood is impoverished and anemia results from the insufficient aeration and poor digestion and assimilation? Costogenic anemia may also be a result. And, third, the shoulders are "round" from the spinal weakness and flattened chest, really an effect; but while the most noticeable, it is the least serious.

It is evident from careful observation and study of these cases that the treatment resolves itself into the treatment of a posterior spinal curvature. Shoulder braces, steel braces and jackets, and casts have very little place, if any, although there may be diseased bone of such character and severity that a cast will be necessary; this, however, would refer to treatment of Pott's disease and similar conditions.

Hence, the =treatment= is, first to replace and readjust the malaligned vertebræ. There must be an actual physical manipulation in order to correct the vertebræ at fault. This is the essential, and by far the primal, treatment for the key to the truss or brace that holds and retains the body in an erect position is then replaced.

Second, raising the depressed ribs. Remember the depressed ribs are dependent upon the spinal condition. The thorax should be treated as a comprehensive whole, not the spinal column alone.

Third, exercises are a valuable aid. The individual's part is as necessary, in a way, as the physician's, for in order to accomplish the maximum there should be consistent and appreciative work on the part of the patient. Holding the shoulders back, the head erect and the chin in, drawing the abdomen in and up, all with deep breathing by the use of the chest muscles, the patient will be able to retain the correction obtained during treatments. "Setting up" exercises are helpful. Developing the muscles of forced expiration is excellent. Thus the patient must be conscious of the work required of him and act in concert with the physician. Minute instruction on the requirements of each case is demanded.

Good food, pure water, and fresh air are necessary, particularly in the anemic. Right living and correct environment are always in order.

Painful Shoulders

Under this heading may come a variety of conditions affecting one or both shoulders causing much distress and, at times, total disability. The conditions may be the result of direct injury to the joint, systemic, or from spinal lesions. Anatomically the shoulder offers frequent opportunity to injury as it has the greatest range of motion of any joint, is least secure in its articulation, and is most vulnerable from location. Once the shoulder has been dislocated it is rarely back to normal functioning again as this injury tears the

capsular ligament and stretches the structures in relation. Many times there is only a =subluxation= in which the head of the humerus is driven upwards in the fossa, usually from a fall or blow on the point of the elbow. As a rule, after such an accident, the only thing done is to rest the joint and apply a liniment and, after a time, begin the use of the arm. It is, however, painful and to save himself, the patient each time restricts movement until he reaches a point where he is unable to dress without assistance. It is then found that normal motion is reduced fully one-half and even this will be accompanied by pain on movement and in bed. A radiograph will, usually, show the condition. Articular crepitus and fibrous adhesions are present while the adjoining structures have undergone changes so that a reduction is impossible without certain preparation. Very often a trivial cause will disable a joint; a sudden movement which finds the muscles about the shoulder unprepared and the resulting lesion is so slight as to, often, defy detection. At first there will be swelling and pain but, in time, it settles down to a limited motion with more or less distress.

=Bursitis.=—This is a condition in which the subdeltoid bursa is involved or where there have been a number of bursæ formed from overuse of the joint. One authority reports as many as twenty-five in a shoulder. There may be, also, tenosynovitis primarily or from extension. These conditions may not be easily diagnosed at first.

=Brachial neuritis= (chronic) beginning with or without an acute attack is usually from a cervical lesion involving the brachial plexus but most frequently it is the 5th and 6th cervicals at the origin of the circumflex nerve. From this the deltoid is particularly affected and its contraction leads to pressure on the nerve and subsequent partial or complete paralysis. Brachial neuritis is found in an increasing number of osteopathic practicians and is the result of overwork of the arms and to strain of the upper dorsals and lower cervicals. There are contractions of structures about the joint constantly limiting motion and pain when a strain is put on them.

Many methods for the treatment of the conditions described have been employed, all involving the same principle but none of them systematized. C. H. Spencer has worked out a technique which, while originally intended for bursitis, has been found well adapted to all conditions described. It gives a stretching of all structures and gradually breaks up adhesions, both in the joint and in the tendon sheaths, so there is no resulting irritation which could easily result if suddenly done. His technique is[43]:

“First: The patient on the side, the affected shoulder up; operator facing the patient, places one hand on the top of the shoulder, does nothing more than fixing it; with the hand grasping the forearm above the wrist, push the elbow backward, the arm parallel to and almost in contact with the body, then pull forward in the same plane. Second: Elevate the elbow with the hands of the operator in the same position as before, carry the elbow in as wide a circle as possible. Third: With the hands still in the same position, extend the forearm with traction; carry it as high in front of the patient as possible. The foregoing are designed to relieve the congestion about the shoulder, bring pressure to bear on the subdeltoid bursa and moderate traction on the supraspinatus, infraspinatus, subscapularis, teres minor and major, latissimus dorsi and the tendon of the biceps. These manipulations will be all that is possible in the more aggravated cases for some considerable period of time. As the tenderness subsides, the second group may be cautiously started, the hands in the same position as above noted, with the arm extended as nearly as possible at right angles with the body, carry the arm in as wide a circle as the pain will permit. Again, with the arm flexed at the elbow, one hand of the operator on the point of the shoulder and the forearm of the patient across the forearm of the operator, the other hand of the operator resting on the point of the patient’s elbow, push down toward the middle line of the body and carry the elbow toward the head. Then flex the arm and place the back of the hand behind the patient, flexing the shoulder in front with one hand grasping the point of the elbow and pull forward. This group of movements accomplishes with greater force the same ends obtained in the previous, and the first in this group is the most effective in overcoming swelling of the subdeltoid bursa. Direct manipulation of the muscle masses and this bursa is desirable from the first.” It will be noticed in all these movements that the joint is protected by one hand of the operator while the other is grasping the arm of the patient. This is desirable as it makes the technique absolutely safe. An additional treatment will be found very effective, especially where the deltoid is involved. With the patient on the well side, facing the operator, locate the quadrilateral space which is bounded by the subscapularis above, the teres minor below and the long head of the biceps medially and the surgical neck of the humerus externally, and the circumflex nerve can be easily palpated along with the artery. If these structures are stretched and the deltoid lifted from the shoulder it will be found to free the action of both nerve and artery, one supplying the joint with nutrition and the other innervating it.

Certain conditions for which these movements are contraindicated arise and the following differential points by H. Glasscock are well to remember[44]: =“Rheumatism=: Fever in the joint, with redness, swelling and other joints involved. =Tuberculosis=: Daily temperature and other tubercular foci. =Neuritis=: Pain in the neck and shoulder muscles, also near insertion of deltoid and in the forearm, particularly musculo spiral. Pain worse at night. No pain on movement. No swelling. =Bursitis=: No pain in neck. Pain in anterior and posterior part of joint and on motion. Pain near insertion of deltoid. Arm held close to the body, motionless. =Infection=: Chill, limited motion, severe pain with temperature. =Dislocation=: Deformity with preternatural mobility. =Dislocation= of

=acromio-clavicular= joint: Tenderness over articulation. Arm cannot be raised beyond right angle with the body, but elbow may be brought across the chest with external rotation of arm and raised perpendicular with the body without pain." The infected joint should never be manipulated and all conditions showing swelling, redness and pain on touch should be viewed with suspicion. Remember that all other conditions will almost invariably have vertebral lesions, primary or secondary and a permanent result will depend upon their correction.

The Prominent Hip

A hip that is prominent and larger than its fellow is of frequent occurrence. It may not be necessarily conducive to a defect in posture, but it often is. The female is more frequently afflicted with this anatomical irregularity than the male. In the first place, the female pelvis is not so stable and rugged as the male pelvis, i. e., a mechanical wrench or fall will more easily displace the relative position of the tissues in the female. Then, in the second place, the dress of the woman accentuates irregularities of the figure, so that possibly in some instances the defect, from a diseased or deformed point of view, is more apparent than real. But of still more importance is the fact that many cases of a prominent hip are due to a lateral curvature of the lumbar spinal column. Lumbar curvatures are of common occurrence in the woman; first, the spinal column is not so strong as in man, simply on account of the physique not being so robust; second, modern dress constricts the waist by the use of corsets and many waist bands, and the weight of heavy skirts upon the waist, hips and abdomen; and, third, severe strains from childbirth. Care should be taken that there is no congenital abnormalities of the lumbar spine, or that congenital asymmetry of one-half of body, or trunk or leg is not present.

Thus the principal =cause= of a prominent hip is the lateral lumbar curvature. This, through compensatory action, renders the hip on the concave side prominent and high, while the hip on the convex side is depressed and less pronounced in appearance. Dressmakers and tailors are all too familiar with this feature of the irregularly outlined figure, and, consequently, have to resort to "padding" to round out the symmetry of the body. The mere irregularity of the figure, unfortunately, is by far the less serious part of the defect. Many ailments and diseases can be readily and directly traced to this. Not that the prominent hip itself necessarily always plays a leading part, but rather the lumbar curvature is the cause of very much suffering and misery. To enumerate the many disorders that arise from malaligned lumbar vertebræ may be unnecessary but a few will be given. A point to be emphasized is that the prominent hip often plays the role of a sign or symptom, or an effect, that an ailment or disease may be elsewhere.

In the female one of the most common causes, if not the most common cause by far, of disorders of menstruation, whether painful, profuse, or irregular, is irritation or obstruction of the lumbar spinal nerves due to lumbar curvatures. It is well known the lumbar spinal nerves control, to a large extent, the pelvic organs; consequently the osteopath pays particular attention to this area. Then certain intestinal disorders, such as appendicitis, typhoid fever, dysentery, rectal diseases, owe their origin to predisposing lesions here; also, bladder ailments, and sexual diseases of men, and many affections of the legs, as sciatica, varicose veins, etc.

In a number of instances the prominent hip will be due to a displaced innominatum. Then a lumbar curvature will result as a compensatory condition. This reverses the compensatory act as heretofore referred to; the prominent hip, in this instance, is the cause and not the effect. To diagnose which is cause and which is effect will frequently require considerable technical knowledge and experience. The slipped innominatum then produces symptoms and disorders directly from its changed anatomical relations; the points of diagnosis are given in the chapter on Diagnosis. The prominent hip can easily be detected when the subject sits down upon an even, firm surface, or stands up, and the one side is compared with the other. In some cases where the prominent hip is due to a lumbar curvature, and the prominence is a secondary feature, the legs will be found uneven in length, but not always, for the lumbar curvature may straighten out when the patient lies flat upon the back. To diagnose the cause from effect and to differentiate the maze of signs and symptoms that may be present is not always easy even for the skilled practitioner.

The =correction= of a prominent hip is not ordinarily a difficult matter. In the cases where lumbar vertebræ are principally at fault, and these include the greater number, the problem is one of correcting the spinal curvature. Lumbar curvatures are the easiest of any of the curvatures to correct, for one is not hampered by the rib articulations, and the lumbar section presents an area where a leverage can readily be obtained. Where the innominatum is primarily at fault it is simply a matter of readjusting this, with probably some attention to the lumbar region. Care should be taken that the prominent hip is not caused by a tubercular sacro-iliac disease, by hip-joint disease, by a dislocated hip, or by an overlapping of thigh or leg bones from fracture.

Standing erect will, of course, be a valuable help, for standing with the weight on one foot will tend to make the hip on that side more prominent. But generally the reason why one favors a certain side is because the other side is weaker; a weak back, a slipped innominatum, or an injured leg are common causes. There are many cases where the skirts will have to be considerably altered

after the hips have been made symmetrical.

Pendulous Abdomen

The =pendulous abdomen= is another defect that is all too common. A great many people have prominent abdomens because they do not stand properly, but a pendulous or prominent abdomen is not necessarily synonymous with a stout abdomen. They attempt to stand erect by drawing the shoulders back and extending the abdomen. If they would hold the head erect and the chin in, with the shoulders back and the chest forward, and draw the abdomen inward and upward, their figures and physiques would undergo shortly a wonderful transformation. These directions also apply to pregnant women. Drawing the abdomen upward and inward will at first require considerable effort. It certainly will not be an involuntary act for the first few days.

The sagging of the abdomen not only causes an unsightly appearance but results in great relaxation of the abdominal muscles, interferes with digestive functions, displaces the pelvic organs, and weakens the action of the lungs and heart.

The laxity of the abdominal muscles allows the abdominal organs—the intestines, stomach, kidneys, etc.—to displace downward. This tends to indigestion, constipation, inactivity of the liver, etc., and causes a score of reflex symptoms. The organs become simply weakened from a lack of proper tone. This is a frequent cause of nervous prostration. Also it is one of the common causes of prolapsed and displaced pelvic organs, because the abdominal organs sag down upon them and the pelvic organs thus receive the brunt of the gravitative effect. Internal local treatment of the pelvic organs can only be a makeshift in these cases. The lungs and heart are weakened because the abdominal organs are dragging on the chest, the lungs can not aerate the blood freely owing to the abdominal weight and to the blood being obstructed in passing from the abdominal organs through the liver to the heart and lungs. The heart is handicapped in its work through lessened chest capacity and obstructed circulation. Just “suck” up the abdominal organs and see how much easier it is to expand the chest and to breathe.

There are other causes for a pendulous abdomen, such as a weakened spinal nerve supply to the abdominal muscles and organs. The weakened nerve supply may cause a loss of tone to the abdominal organs themselves, so that certain organs, as the stomach and intestines, become dilated and prolapsed; to the ligaments, and to the tissues and organs as a whole so that they become gravitated.

Through childbirth muscular fibres of the abdominal walls often rupture, leaving scars and a relaxed condition. Actual ruptures, hernia, of the abdominal muscles occur and cause a pendulous abdomen. Then there are cases of obesity where the pendulous abdomen is a symptom.

Much can be done with all of these conditions through osteopathic work; the patient must also help himself. The center of gravity of the body must be changed, and kept changed; correct posture and a constant effort will accomplish considerable. The “setting up” military exercises are excellent. Even in some cases of obesity the abdominal prominence can be markedly lessened by careful exercising and keeping the abdomen drawn in so that the abdominal muscles, the diaphragm, and the chest may be strengthened. For the relaxed, flabby abdomen, self manipulation of the weak muscles when lying on the back will materially aid.

Postural Curvatures of the Spinal Column

Undoubtedly, the great percentage of postural defects, or slumped states, are dependent, directly or indirectly, upon weaknesses in the spinal column. As was seen, round shoulders, the prominent hip, or the pendulous abdomen, are often initiated by spinal deviations and deformities, so naturally spinal column curvatures are a most fruitful source of direct defects of posture.

It is somewhat uncommon to find an anatomically true spinal column, although this does not preclude that one’s posture is defective, for often through pride and effort one may consciously overcome a defective posture.

It is the purpose here to offer a few suggestions relative to the development of a greater symmetry of the body. Nearly every one is more or less interested in physical exercises and development. And especially to those of sedentary habits do means and methods of exercise appeal. Curiously enough, in a way, nearly every layman looks upon defects in posture, symmetry and stature as an effect arising from lack of, or improper, exercise. He seems to be imbued with the idea that the body in most instances is practically permanent in construction and when irregularities in figure occur certain exercises will correct the defect. Thus have individuals been prone to look upon osteopathy as a method of passive exercises. Osteopaths should believe most thoroughly in exercising, personal hygiene, etc., but the idea of osteopathic manipulation is primarily one of anatomical reconstruction, and not muscular development alone. The work of the osteopath is to readjust or to re-mold the body framework and the many tissues that clothe it

so that normality of function may predominate. The manipulation is not routinism but mechanical rebuilding of the tissues so that perfect freedom of vital forces may be forthcoming.

The spinal column presents the most frequent as well as many extremely interesting phases for re-correcting work. The number of abnormalities as to contour to which it is subject are many and varied. Emphasis should be placed upon possible congenital abnormalities and developmental defects as sources of certain derangements. Any variation or combination of variations with the normal or physiological curves constitutes an abnormality or pathological curve. And as a consequence defective posture, unless thoroughly compensated, is readily initiated. Not only may the normal curves be exaggerated, lessened, eliminated or reversed, but lateral and rotary curvatures are of frequent occurrence.

Curvatures involving the cervical region to the extent of producing noticeable defects of posture are principally lateral deviations of several vertebræ. Wry-neck is probably the most noticeable disturbance. The head and neck being drawn and slightly twisted to one side is a defect that is both noticeable and painful. Another common source of postural affection is an exaggerated forward curving of the neck vertebræ. This produces a stooped appearance of the neck.

The dorsal vertebræ are often curved backward too far. This produces roundness with too decided a fullness of the upper back and shoulders. The chest may be somewhat flattened as a secondary effect but not necessarily so. Neither are the shoulders what may be termed “round shoulders,” still such a condition may occur, for “round shoulders” are more often caused by a backward swerve of the column at the waist line. There is often a shortening of the anterior structures which pull the point of the shoulders forward. Forcing them backward will aid in correcting the fault. The dorsal vertebræ may be forward from what is termed a “straight” spine; this results in an exaggerated “braced” back position. Then lateral curvatures of the dorsal spine are common, which in time may develop into a rotary curvature; that is, the vertebræ are actually rotated on their axes. Lateral curvatures of the dorsal spine are slow and difficult to correct, for the ribs complicate matters very materially. Then, also, the vertebræ are apt to be deformed.

Curvatures of the lumbar spine, whether posterior, lateral or anterior, are common. Both dorsal and lumbar curvatures, as any one can readily see, are extremely common sources of postural defects. Erect positions of the body are maintained through the support of the dorsal and lumbar vertebræ. Stooped shoulders, one shoulder lower than its fellow, sitting humped over, sitting on the sacrum instead of squarely on the buttocks, the prominent hip, standing first on one foot and then on the other in order to rest the back, and the many allied variations of incorrect postures are largely dependent on the condition of the lumbar and dorsal spines.

It is not to be supposed that the above defects are the only ailments and disturbances that spinal curvatures cause, for, indeed, the defective posture may be by far a minor consideration. Disorders of body functions and affection of organic life itself are very often traced to the malaligned vertebræ.

The =causes= of spinal curvatures are many, but without question one of the most common causes is mechanical wrenching or twisting of the column from falls, jars, etc. Often the strain or sprain of the sections are readjusted through the inherent powers of the body, but there is a point where _vis medicatrix naturae_ requires extraneous help to correct the perversion; and, naturally, such aid, by virtue of the cause of the disturbance, should be physical force mechanically applied. Other causes of spinal curvatures are contractions of muscles on one side of the column or paralysis of the muscles on one side; in either instance, muscular action is greater on one side than the other, which easily results in a curvature. This imbalance of muscular tension, whether due to the above or other sources such as overfatigue or various deleterious habits, is a prolific source of lesions. And among still other causes may be noted, bone diseases of the spinal column, compensatory deformities, and constitutional weakening and irritating diseases. Also, some occupations predispose to certain curvatures.

One can readily see that the =treatment= which is directed specifically to the cause of the vertebral deviation would be the most scientific. This is just what osteopathic work implies, direct readjustment of the sections at fault—not exercises, or routine stretching, or braces; although these latter methods may in some cases have their place as secondary aids. Of course exercises are usually physiological and may be employed, in many instances, as an auxiliary. Care should be taken to eradicate infectious foci when present.

Where curvatures are extreme, complicating and deforming the ribs, and absorbing the bodies of the vertebræ so they become wedge-shaped, and resulting from abscesses, no one can expect within reason to absolutely correct the posture. Some aggressive work can be accomplished, but a perfect symmetry will not be forthcoming. It may be well to emphasize again that where the ribs are involved the osteopath is not contending with the deformity of the spinal column alone, but in addition the entire transverse area of the body. (See also Spinal Curvatures).

=Conclusion.=—In concluding this rapid survey of a number of postural defects the principal lesson to be drawn is not one of developing the physique and thus perfecting a better posture, so much as curtailing and eliminating insidious beginnings of disease. These little ailments and deformities, of which postural defects may be the most noticeable, are so often the inception of more serious disorders. The anatomical structure being maladjusted, -aligned, or -positioned, easily and readily leads to consequences that require much time and patience to overcome.

Poise of body represents much to every one. Poise or correct posture coupled with careful and methodical exercise and correct breathing are material aids in constructive development, as well as in eliminating disease, for not alone may abdominal, pelvic and thoracic integrity be benefited, but the upper respiratory tract may be toned.

The most important goal that osteopathic science and art is striving for is that of a fully developed and rounded out prophylaxis or preventive treatment. When the public realizes that the proverbial ounce of prevention is an established medical reality then it can truly be said our science has reached its ultimate good. To those who are familiar with osteopathic theory, facts, and development, it is an open secret that this school holds the key to successful preventive treatment. The time is rapidly approaching when the actual lessening of diseases will be an established fact. Then will be the universal practice of the layman going periodically to his osteopath to see if there are any small or insidious beginnings of disorder or disease.

Not only must the many deleterious habits and errors of the daily regimen be corrected, but after environmental, physiological and structural adjustment, in so far as possible, has been attained, a daily regimen to maintain the normal should be instituted.

[44] Osteopathic Physician, Nov. 1919.

PROLAPSED ORGANS

Prolapse of various organs or tissues are among the very common ailments that afflict all classes. Prolapse of the stomach, a kidney, the uterus, or the rectum is a familiar term to every one. But this condition may also rest with the intestines, the liver, an ovary, or even the heart.

Outside of injuries, congenital weaknesses, and so-termed surgical disorders, there are commonly two constant forces predisposing to prolapsed organs, viz: gravitation and weakened innervation; the one, of course, is a constant factor in either health or ill health, the other is dependent upon acquirement. Here the latter, or acquired nervous weakness, will especially demand our attention.

Where tissues are torn or lacerated, or congenital malformations are present, or tissues are weakened from ulceration and with a resultant scar tissue, or certain tumors are present, the disorder must be amenable largely to surgical measures if at all.

The perpendicular position of the body favors a decided gravitation of the abdominal and pelvic organs. This gravitative effect being a constant one, many methods, both surgical and mechanical, have been devised to hold in approximate and relative position certain organs and tissues that may be prolapsed. But it is well known that outside of a certain few instances where surgical measures are clearly indicated the prevalent use of braces, bandages, supports and the like are usually poor makeshifts.

The one great feature in these cases is that tonicity to organs and supporting muscles and tissues is more or less impaired. The tissue atony may vary from mere weakness to actual tearing and separating of the fibres. The indications in the cases about to be described are to stimulate a lowered nerve supply and to increase a lessened blood supply; if this can be accomplished, supporting muscles, ligaments and other tissues will be able to restore the prolapsed organs to normal positions, thus improving functions and eliminating disease symptoms.

In discussing the prolapse of the following organs, perhaps it should be noted here that all of the abdominal organs may be prolapsed as a whole. The intestines, stomach, liver, kidneys, etc., may actually prolapse together. This is more apt to occur in persons whose abdominal walls are thin and flabby. In women pregnancy is a common cause. When the abdominal organs have gravitated, the pelvic organs, also, are very likely to be disturbed and displaced; in fact, the pelvic organs are frequently disordered this way.

Prolapse and Dilatation of the Stomach

Dilatation of the stomach is a much more common and serious affection than prolapse of the stomach, although usually the two are associated. Prolapse, or ptosis, of the stomach means simply a downward displacement of the organ. This is apt to take place in those cases where all of the abdominal organs have gravitated. There is invariably some dilatation of the organ as well.

Weakness of the abdominal walls and of the supports of the stomach constitute the principal =causes= of the prolapse. Spinal deviations that impinge or obstruct the nerve strands (or obstruct the blood and lymph supply to these strands) to the supporting stomach tissues is the most frequent cause of the ailment. General debilitating diseases, as anemia, cancer, etc., are indirect causes of weakened organs with consequent displacements.

In dilatation of the stomach the condition may be either acute or chronic. The former is found where immense amounts of food or drink have been introduced.

One of the principal causes of chronic dilatation is some obstruction to the opening from the stomach into the intestine, so that the stomach contents do not pass readily into the bowel. This leads to chronic disturbances of the stomach walls, and the food remaining in the stomach somewhat indefinitely weights down and stretches the walls of the stomach. The obstruction may be a tumor, or some stricture or adhesion from scar tissue resulting from ulceration or inflammation. The treatment of these cases comes within the province of surgical interference rather than other methods.

The second important cause of chronic dilatation is muscular weakness of the walls from poor nerve supply. This is a common cause and osteopathy is very successful in curing these cases. The splanchnic nerves are below normal, usually from a slight lateral or posterior spinal curvature. The nerve force to the walls of the stomach not being normal causes atony of the muscles and dilatation results. This nervo-muscular atony, also, results from a chronic catarrh, or from a general nutritional disorder as tuberculosis or anemia. The treatment of the former would imply direct correction of nerve and blood supply with attention to diet; the latter can be cured only through relieving the nutritional disorder of which the stomach condition is a symptom.

Dilatation of the stomach is most common in people of middle age or older. The disease is usually easily diagnosed. The symptoms may not be indicative of the trouble beyond showing that the stomach is disturbed. Indigestion, uneasiness, and nausea are common. Vomiting of large quantities of material from the stomach is likely to occur. The patient is generally emaciated, the skin is dry, the bowels constipated, and the urine scanty.

The =diagnosis=, as a rule, is not hard to make. Through the media of inspection, palpation and percussion, the careful osteopath will have little trouble to determine the size of the stomach. Kemp's[45] distinction between gastroptosia and dilatation of the stomach is as follows: "In dilatation the lesser curvature retains its relation to the diaphragm. The distance between the lesser and the greater curvature is increased, but the lesser curvature still maintains its relation to the diaphragm, with the exception that the pyloric end may extend farther over and somewhat farther down." Another instructive point relative to diagnosis the above authors make is the importance of the splashing sound. Owing to the fact that the stomach in health closes concentrically about its contents and thus adapts itself to the volume of ingesta, no splashing sound can be elicited. Three different degrees of relaxation are diagnosticated as follows: "Splashing sound, which can be elicited only during the normal period of digestion, means simple atony; splashing sound produced after the legitimate time of digestion has expired means motor insufficiency; and splashing sound produced in the morning, after the night's fasting, before liquid or food has been introduced, may mean stagnation, dilatation of the stomach, as understood by most writers." (For a more complete outline see Dilatation of the Stomach. The object of this section is to present an outline of prolapsed organs as a whole, and to refer especially to the effectiveness of osteopathic treatment in this condition).

This is a disease where osteopathy has been particularly successful in not only relieving distressing symptoms, but in actually curing the disorder. This refers to the nervo-muscular atony type, for where there is obstruction due to stricture or tumor of the pylorus, resulting in stomach dilatation, the treatment, from the very nature of things, must be largely surgical. Stomachs that have been dilated and prolapsed several inches have been entirely restored to function and organic integrity. To =cure= these cases is a matter of stimulating nerve control and blood supply to the stomach tissues, and, often of greater importance, removing spinal impingements to the stomach nerve fibers, thus allowing nature to fully assert herself. In reality, outside of so-termed surgical cases and other cases where the stomach dilatation is merely a symptom of general nutritional disorder, the primary treatment, by far, is the spinal one. Treatment over the stomach is a decidedly beneficial treatment; it aids materially in toning both abdominal and stomach muscles; still this is mostly a secondary treatment.

Dieting is essential. Careful dieting lessens the tendency to catarrhal inflammation and reduces the work of the stomach to a minimum. Still, nourishing food is necessary and the dieting can easily be carried to an extreme. Liquids should not be taken freely. Fatty and starchy foods should be eliminated. Give the patient food at short intervals. Various nutritious meats are excellent.

In dilatation, and also general abdominal relaxation, daily abdominal treatments may be indicated. If the relaxation is pronounced, keeping the patient in bed with thorough spinal treatment two or three times a week, daily abdominal treatment, having the patient exercise abdominal parietes by drawing the walls in and up, upper thoracic breathing, and frequent feeding will accomplish comparatively quick results. The progress of each case depends very materially upon the general health, the physical status of other tissues, constitution, inheritance, environment, age, etc. Some cases will yield in two or three months, others will require two or three years in order to obtain the greatest possible benefit.

The Prolapsed Kidney

A =prolapsed kidney= is often termed a floating kidney, or movable kidney, or dislocated kidney. It is of common occurrence, especially in thin persons. Some authorities state that one woman out of every four has a floating kidney. It is more common in women than in men, and among the working class than other classes.

The condition is usually an acquired one, following severe strains from lifting, falls, injuries, etc. It is claimed by some that a floating kidney arises from congenitally weakened and relaxed tissues about the kidney, that is, the tissues that keep the kidney normally at anchorage. Thus a congenital looseness of the kidney would easily be a predisposing cause whence mechanical violence, repeated pregnancies, an enlarged liver, or tight lacing would act as an exciting cause. Undoubtedly in some instances there is a congenital predisposition, the peritoneal fold attaching the kidney to the spine being loose and the capsule of fat retaining the kidney being scanty, but osteopathic experience has amply demonstrated that the tissues anchoring the kidney may in many case become atonied and relaxed from lower dorsal spinal lesions. Rarely is a case presented to an osteopath that does not exhibit two apparently characteristic causative features, viz: spinal irregularity in the lower dorsal spine, and constriction of the zone about the waist, i. e., dropping and constricting of the floating ribs. Furthermore, correction of these lesions will almost invariably lessen the mobility of the palpable kidney.

The =symptoms= of a floating kidney are many and variable. The kidney may be slightly movable or it may be so loose that one can easily grasp it through the walls of the abdomen. Most of the symptoms are of a nervous reflex nature. Indigestion, which is likely to be very persistent, flatulency, heart palpitation, painful menstruation, irritable bladder, etc., are the most common symptoms. Still, blueness, depression and morbidness are frequently present. The most distressing direct disturbance is the feeling of weight in the abdomen, especially on standing, running or lifting. Sometimes the ureter becomes twisted and severe pain, colic and even collapse occurs. (Dietl’s crisis.)

The =diagnosis= of a dislocated kidney is not a particularly difficult matter. A little experience coupled with a delicate sense of touch will usually readily detect abnormal mobility of the kidney. A point to always remember is that the kidney normally descends about one-half an inch with each inspiration. Care should be taken not to mistake a floating kidney for a movable spleen, although this is not likely, as the shape of the spleen is different.

The =treatment= of a movable kidney under osteopathic measures is usually successful. In the first place a number of cases require but little attention, simply toning up the general health, and especially directing attention to the abdominal walls and organs. There are a number of cases where the kidney prolapse is incidental to general abdominal laxness and weakness. In more severe cases, treating the spine, raising the floating ribs, carefully manipulating over the abdomen, keeping the bowels open, and lessening liver congestion should it arise, will suffice; in fact, will remedy a good percentage of the cases. With others, a well fitting, medium width, elastic bandage with pad underneath will be beneficial. In these cases the patient should be taught how to treat the abdominal organs, to manipulate the abdominal walls, and to replace the prolapsed kidney; particularly after going to bed this can be done successfully by the patient and will prove a decided help in obstinate cases.

=Surgical measures= for fixing the kidney should seldom be resorted to. If the patient will live a careful life, avoid unduly straining himself, keep the bowels normal, and have the anatomical lesions corrected, he will come very near being entirely relieved, if not absolutely. Surgical measures are not always a success. Surgeons are not operating for this disorder so often as in past years. (See Movable Kidney—Diseases of the Kidney.)

Liver Prolapse

This is commonly termed a =floating liver=. There is prolapse of the organ as well as its being abnormally movable. It is not of frequent occurrence; women suffer from it much oftener than men.

Normally, the liver is partially held in place, in the concavity of the diaphragm, by a number of peritoneal folds. The attachment of these ligaments is to the spine and the diaphragm; their principal function is to prevent extended lateral movements. Of greater importance in supporting the liver in a normal position is the integrity of the abdominal walls, and the position of the stomach and intestines. If the abdominal walls are of normal tone the liver is very apt to be in correct position. And the rest of the abdominal organs, especially intestines and stomach, act as a cushion support. Often when the liver is displaced the remaining abdominal organs are, also, out of normal position and relation to each other; in fact, general prolapse of the abdominal viscera is a frequent cause of liver prolapse. An additional support of the liver is a certain cohesion of the liver and diaphragm, and the elastic traction of the lungs.

Foremost among the =causes= that predispose to inelastic and atonied abdominal walls are spinal irregularities, deviations, and curvatures, which impinge nerve force and obstruct blood supply. These same lesions weaken ligamentous supports of the liver and lessen tonicity of the other abdominal organs, so that local or general displacements are readily forthcoming. Strains, injuries, frequent pregnancies, etc., also act as causes that weaken the supports of abdominal tissues and organs. In a word it is very often the pendulous abdomen that is the immediate cause of a floating liver.

It is very rare to find the liver displaced to the lower region of the abdomen. The ptosis is usually somewhat slight. The organ generally rotates on descent, the right lobe being the lowest portion, owing to the attachment of a ligament, the ligamentum teres, to the umbilicus. Probably in some cases there is a congenital tendency to relaxation of the ligaments, and, thus violent exertions and atonic and flabby abdominal walls and diaphragm are secondary but important factors.

The principal =symptom= of a floating liver is a tumor in the right side, which may be low down. Palpation will usually determine this. Then the abdominal walls are flabby. Pain and bearing down of the right side are common. There is apt to be considerable indigestion. Various reflex symptoms are often present. The floating liver will seem larger than normal, as the liver is below the costal arch and much of it can be felt. Percussion will be of value in determining the extent of the disorder.

Much can be accomplished by =treatment=, especially where the displacement is of a lesser degree. Correcting the spinal lesions, toning up the abdominal walls and diaphragm, and replacing the displaced organs will be extremely effectual. The abdominal bandage may be of service. Certainly abdominal exercises will be beneficial.

A point to remember is, stimulation over the abdomen beneath the right costal arch will cause the liver to contract and retract. This is of considerable osteopathic note. The liver will often recede at least a half an inch. This is a liver reflex (Abrams).

Prolapsed Intestines

=Prolapse= of the =bowels=, as a whole, or, more frequent still, of a part, is undoubtedly the most common form of organ prolapse. The intestines are so situated that they readily feel the effect of gravitative influences, of atonic and anemic states, and of weaknesses and disorders of other abdominal organs.

Spinal irregularities come first as potent =causes= of bowel prolapse. The spinal nerves to the supports of the intestines, to the muscular coats of the intestines, and to the abdominal walls, are obstructed in their normal activity, and consequently those tissues to which these nerves are distributed are affected. Wasting diseases, as anemia, consumption, cancer and the like predispose to intestinal atony.

The severe mechanical wrenches, strains, frequent pregnancies, tight lacing, heavy skirts, large abdominal tumors, obesity, cause more or less general or local weakness.

The pendulous abdomen, from wrong or careless posture, and exclusive of other causes, is a common source of general bowel displacement. This form of disorder, besides being unsightly, favors abdominal stoutness. There are a number of instances where simply voluntarily holding or “sucking” the abdomen into place, until it becomes strong enough to support itself, has reduced one’s weight by five, ten or fifteen pounds. These were cases where most of the adipose tissue was about the abdomen. Thus exercising and toning the abdominal organs by keeping them in normal position rectified a dormant blood and lymph circulation, which was followed by absorption of the abdominal stoutness.

Congenital weaknesses are to be considered in many cases. The muscular ligaments may not be developed, the mesenteric attachments may be too long, and various other abnormalities may result from congenital disturbances.

Of particular local interest to the osteopath, outside of the bowels dislocating as a whole, are: first, the hepatic flexure; second, the ileo-cecal region; third, the sigmoid flexure; fourth, the rectum; and fifth, hernias. Each of these sections are of separate interest and will be considered presently.

The =symptoms= are extremely variable. Constipation, a feeling of discomfort in the bowels, nervousness, depression, lassitude and anemia are frequent. Colicky pains in the intestines, indigestion, hysteria at times, are also among the symptoms. In reality a great variety of symptoms may be present. The patient is likely to be emaciated. In some cases exhaustion is marked.

=Diagnosis=, as a rule, is not a difficult matter. The various neurasthenic symptoms in a lean patient with constipation, indigestion, and stomach and intestinal distress would lead one to suspect intestinal displacement. The outline or contour of the abdomen will often reveal the character of the trouble. The atonic, thin and relaxed walls of the abdomen may readily give view of the displaced organs. Then careful examination by palpation and percussion will help very materially in the diagnosis. Radiographic examination is a decidedly helpful diagnostic method.

The =hepatic flexure= is frequently prolapsed. The bowel (colon) ascends from below upward to beneath the costal arch and then angles sharply into the transverse colon, which extends directly across the abdomen to the left side. The ligaments that support this flexure are apt to become weakened or stretched and allow a descent of this section of the bowel, which is followed by constipation, indigestion, etc. The ligament especially involved is the colo-hepatic ligament. The =duodenum= may require attention. This can be raised by getting beneath it where the organ descends alongside of the ascending colon. The effect of treatment is to release tension of the duodeno-hepatic ligament which is closely associated with the portal vein, hepatic artery and bile-duct.

The =ileo-cecal region= is an area that readily becomes congested and catarrhally inflamed, especially from constipation or impaction at this point. The section often becomes atonic and prolapsed with resultant clogging of fecal matter. Owing to the close proximity of the vermiform appendix, appendicitis frequently results from the above condition. The osteopath can do much in these cases of appendicitis. Lesions are invariably found in the lumbar vertebræ or the floating ribs are depressed.

The =sigmoid flexure= is also frequently prolapsed. The fecal mass often becomes impacted here, owing to a settling or prolapse of this part. In some cases the prolapse is so marked that it extends to the rectum below and drags on the splenic flexure above.

Lumbar and innominate lesions are the usual causes, although, it seems in a number of instances, that relaxed walls of the abdomen cause a “contraction of the diaphragm resulting in kidney displacement and followed by intestinal prolapse.” The vertebral lesions, probably, first weaken the muscular coat of the bowel, then, second, the bowel supports (other than its own inherent tonicity) and the abdominal walls.

Prolapse of the =rectum= is of such separate importance that it will be but partly outlined here. As stated above, a source of rectal displacement arises from the section of the bowel above settling downward and ultimately causing invagination of one or more coats of the rectum. Dislocation of the coccyx is a potent cause of rectal disorders. Lumbar lesions, especially twists between the fourth and fifth, and fifth and sacrum are common causes of rectal weaknesses. Slips of the innominata are other causes of prolapse.

Osteopathy has had marked success in these cases. Cures may result from a single treatment to readjust the coccygeal displacement or temporarily relieve excessive physiological activity by dilating the rectal sphincter, or the treatment may demand a number of months’ work in correcting general abdominal prolapse. Raising the sigmoid is effectual.

A =hernia= is “the protrusion of a loop or knuckle of an organ or tissue through an abdominal opening.” Two of the common hernias of the intestines are inguinal and femoral. These conditions are most often acquired from severe straining, so that a loop of the bowel protrudes through a weakened and stretched area of the abdominal walls, though there is reason to suspect that congenital defects are often predisposing factors.

Mention of the hernia is here made because, in a way, it is a form of bowel prolapse; that is, a limited form, and osteopathy contains certain possibilities for a successful treatment. Hernia has always been looked upon as purely a surgical disorder; i. e., remediable by surgical measures only. Where a truss has failed to give relief surgery has been resorted to. This is true in most instances, but

where the hernia is in the incipiency careful abdominal exercises (this should be carried out with great care, for severe exercise may produce a hernia or increase one already existing), massage to the tissues about the hernia, attention to the bowels, and spinal stimulation corresponding to the weakened tissue, and avoidance of strains may strengthen the tissues materially about the hernia.

Occasionally a loop of the intestine will prolapse into the cul-de-sac back of the uterus. A heavy dragging pain low down in the center of the abdomen and constipation or complete obstruction are the pronounced symptoms. Careful lifting of the loop of bowel by pressure within the vagina and traction from above with a hand outside, with the patient, on her back, with buttocks elevated, gives speedy relief.

The =treatment= of the prolapsed bowels represents those measures that will replace and keep in position the displaced organs. Naturally, the spinal and abdominal treatment comes first; this strengthens intestinal ligaments, tones intestinal muscles, and contracts the abdominal parietes, and at the same time the bowels are regulated, digestion and nutrition improved, and the general health built up. In some cases abdominal supporters will be of value. In a number of instances attention to chest mobility and diaphragm tonicity will be of value. Right living, which is represented by proper diet, sufficient outdoor exercise and regular habits, is invaluable.

The really specific treatment is to correct spinal, rib and innominate deviations and abnormalities. But direct local work will be, in many instances, necessary. General abdominal manipulation is good, but this should be supplemented by careful local treatment. The hepatic flexure requires a direct stimulating and replacing treatment. The ileo-cecal section should be raised, stimulated and emptied of the fecal mass. Direct upward manipulation of the sigmoid flexure in the left iliac fossa and of the splenic flexure beneath the left costal arch is extremely efficacious. Care must be taken not to bruise the parts. Getting beneath the prolapsed area and gently and intelligently raising the bowel so that it is emptied, toned up, and vascular congestion relieved, are the indications. This requires careful work and the necessity of gentleness can not be emphasized too much. Still in all of this treatment we should never forget the absolutely essential spinal readjustment.

Rectal prolapse requires lacol internal treatment, external tissue correction, especially of the coccyx, an innominatum or the lumbar spine, and, of much importance, deep, careful and thorough work over the sigmoid section.

Cases of bowel prolapse are every day experiences with the osteopath. The osteopathic treatment is of great value in these and a successful issue is very often the result. Cases of pendulous abdomen, of obstinate constipation, of chronic indigestion, of many nutritional disorders, of feeling pain, weight or dragging, locally or generally, in the abdomen, are very apt to be in persons suffering from prolapsed intestines.

A number of cases of bowel prolapse are associated with general prolapse of abdominal organs; that is, displacement of the stomach, kidneys, liver, spleen, etc. This general condition is termed enteroptosis or Glenard’s disease. It usually requires several months to treat it successfully. These patients are neurasthenic, malnourished, and often hysteriacs. The symptoms from which they suffer are innumerable. Mechanical weaknesses, lowered vitality, poor innervation and blood supply, and auto-intoxication are causative factors.

The Prolapsed Uterus

=Prolapse= of the =uterus= is of common occurrence. The prolapse may be incomplete or complete; the latter when the organ is presented to the external world. Of special interest are those affections exclusive of surgical cases. Ptosis of the abdominal organs upon the pelvic organs is a common cause of uterine prolapse. The abdominal prolapse crowds uterine space, congests the uterus, weakens the ligaments, and drives the uterus downward as a wedge.

Lumbar spinal curvatures are frequent causes of prolapse, as well as other displacements of the uterus. In this region vasomotor nerves to the pelvic organs make their exit, and, consequently congestions, inflammations, and weaknesses of supports are results. Also, slips of the innominata disturb the pelvic circulatory balance. Weakness of the uterine support from below, the vaginal walls and perineum, most often arises from lacerations at childbirth. Still, the vaginal walls may become relaxed through other causes. Tumors and extreme congestions are causes of prolapse. Heavy lifting is quite a frequent source of uterine displacements. Osteopathy is very successful in uterine prolapses; that is, any displacement of the uterus not of a surgical character. Correction of the external causes comes first. Then local treatment to replace, tone, and relieve congestion, and break up adhesions is necessary. The external treatment is usually the primary treatment. Local work is not always necessary. Lacerations and other

surgical indications, of course, require surgery.

Ovarian Displacements

The ovaries may be prolapsed, the left much oftener than the right. When prolapsed, it drops backward, downward and inward.

Ovarian congestion, tumor, retroverted or retroflexed uterus, tubal disease, and pregnancy are among the principal causes. Back of these congestions, tumors and uterine displacements, are the osteopathic causes, particularly spinal and rib lesions from the ninth dorsal downward. Specific lesions at the ninth and tenth dorsals and corresponding ribs, affecting directly ovarian tissues, and lumbar and innominate lesions and abdominal prolapse disturbing uterine and tubal tissues, are the most frequent osteopathic causes. A retroverted or retroflexed uterus is often found. Uterine displacements bear down upon the ovary and cause its descent, and also disturb ovarian circulation.

As has been stated, the left ovary is more apt to be displaced than the right. This is owing to the absence of a valve in the ovarian vein on the left side, and also, this vein opens at a right angle into the renal vein; this anatomical feature easily leads to passive congestion of the ovary, and thus to diseases of the organ. Then the rectum is on the left side and large fecal masses are apt to crowd against the ovary, which tends to its displacement.

Thus it is readily seen that osteopathic treatment is very applicable to ovarian displacement unless the indications are surgical. A more or less constant burning or sharp pain in the ovarian region, with probably some feeling of weight, profuse and painful menstruation, depression, irritability, etc., are =diagnostic=. However, a local examination will reveal the status of the ovarian position and congestion.

The same =treatment= as in other organ prolapse is indicated: toning weakened tissues, relieving congestions, replacing organ, with careful attention to the bowels and the general health. There are no tissue disorders of any part of the body wherein osteopathy is more thoroughly indicated and the results more generally satisfactory than in prolapse. And especially should it be remembered that in prolapse of various organs many vague intestinal and pelvic disorders and even ureteral and bladder disturbances may be traced to bowel dislocations and excessive kidney mobility in which osteopathic measures are often successful.

=Conclusion.=—The purpose of this section on Prolapsed Organs has been to supplement the various articles on Dilatation of the Stomach, Movable Kidney, etc., with an outline that may include relaxation of a part or of the whole of the abdominal viscera. The physician is all too prone to simply note the most offending or conspicuously disturbed organ instead of carefully analyzing all the features, great and trivial, that may be either apparent or marked. A general relaxation of the abdominal and pelvic organs may be found, and a nearly complete restoration take place under treatment, but still a lacerated perineum may have to be repaired before a cure is completed. Or it may be in a general abdominal ptosis that a floating kidney will resist all measures for restoration, short of surgery, and before much improvement can be obtained the kidney will have to be stitched into place. An enlarged liver may crowd the kidney out of place or a transverse colon may prolapse and drag on contiguous tissues and still the annoying symptoms be referred elsewhere. Then the primal point of general relaxation may not be in one organ, but there may be a simultaneous displacement of several.

The thorax itself may be distorted from various diseases so that the chest is narrowed, the diaphragm displaced with consequent descension of the abdominal organs, and from the latter a displacement of the pelvic.

“Far down displacement, marked changes of form, and real disfigurements of the stomach are found in some cases of kyphosis and scolio-kyphosis.”[46] The osteopath will not only find this true in some cases, but in many cases, although he recognizes as causative factors injuries to the spine causing curvatures and postural defects as prolific sources of abdominal relaxation.

“Glenard’s whole theory of splanchnoptosia is based on the relaxation of the suspensory ligaments of the intestines, especially that of the transverse colon; and Stiller, the discoverer of the floating tenth rib, says that splanchnoptosia is a descent of the atonic stomach, of the colon (especially the transverse portion), of the kidney (the right or both kidneys), exceptionally of the liver or the spleen. A descent which has been developed mostly in tender age, in consequence of general relaxation, especially of the peritoneal suspensory ligaments in individuals with congenital general dyspeptic neurasthenia, tender muscles, lean habit, and slender bone structure, manifested in a higher degree by a floating tenth rib.” Stiller observed that when there is a floating tenth rib there is a displaced stomach and a floating kidney, although it is not found in every case, but never missing if the case is pronounced. The tenth ribs in these cases have only a ligamentous fastening and are as freely movable as the eleventh and

twelfth.

That abdominal relaxation plays a very important part in many diseases of the abdominal and pelvic organs, in cardiac and pulmonary affections, disturbs the circulation in the legs, and is the source of many reflex affections no one can gainsay. The osteopath should always pay particular attention to tonic condition of the abdominal viscera, for relaxation of the suspensory tissues and walls, and atony and sluggishness of the organs are frequently paramount etiological factors. And the osteopathic treatment is the remedy par excellence.

SKIN DISEASES

Various skin diseases have been treated osteopathically with varying success. So much depends upon the cause of the disturbance and its removal, in skin diseases, that the cure does not rest so much with the mere treatment, as with the necessary skill in locating the disturbing factor. One has to be continually on his guard to locate external irritations and disorders of the digestive and genito-urinary tracts. A great deal depends upon the avoidance of external influences; eating nutritious food and having an unobstructed circulation. The leading object of osteopathic treatment is to free the circulation and thus promote a healthy and unobstructed flow of blood; in no other class of diseases is this more essential than in skin diseases. After the removal of cutaneous irritations and the correction of internal disorders, the cure of the case depends upon the removal of constrictions to the cutaneous blood-vessels. The osteopath corrects the lesions found, relaxes the muscles thoroughly and stimulates the circulation to the parts involved, and promotes a healthy activity of all the excretory organs. When the upper part of the body is affected, lesions are generally found at the atlas and axis, and when the lower part of the body is affected, lesions at the fifth lumbar are of common occurrence, although lesions may be located at various points corresponding with the seat of disturbance. The constant use of hot baths will be found a helpful measure in many skin diseases. But use of soap must be considered as too much alkali will neutralize the oil of the skin and cause undue dryness, but bran may be substituted to advantage. Cleanliness is necessary but the result sought is, also, flushing the cutaneous vessels. There are many cases where a specific vertebral lesion will cause, through the peripheral nerves, a cutaneous irritation with intense itching and discomfort. This, in turn, produces an exudate with or without a crust and a condition results which is not amenable to any local or constitutional treatment but an adjustment of the lesion will in most cases bring immediate relief. Application of this principle will aid greatly in treatment of any skin disease. In no disturbance of health is it more necessary to find the cause than in skin disease and once found to apply specific treatment.

=Eczema= is frequently met in osteopathic practice. It is the most common form of skin disease, comprising nearly one-third of all these disorders. For a differential diagnosis of the several varieties the student is referred to special texts. It is well to remember that the same underlying causes may be basic to the various forms, for several varieties may occur at the same time or one variety pass into another, though commonly one form is more prevalent. The limbs, face and genitalia are the most common sites, though the eruption may occur on various parts of the body.

=Etiology= includes a number of factors, constitutional and local. Dietetic errors, indigestion and faulty elimination comprise the principal underlying causes, often manifested through absorption of toxins and leucomains. In fact any disorder of the abdominal viscera, organic or functional, may be a predisposing factor, likewise various disorders of the pelvis, tuberculosis, diabetes, anemia, etc. should be considered. So-called gouty and rheumatic tendencies may be the constitutional basis.

The many osteopathic lesions play a very important role in lowering not only systemic resistance but of local tissue as well. This feature can not be over-emphasized.

Then local irritants, mechanical, chemical and thermal, are not to be neglected. These are usually of secondary importance. Micro-organisms are probably a complicating factor after the lowered resistance has been established. Vasomotor neurosis, through constitutional defects, toxins and the very significant osteopathic lesion, is probably an essential part of the pathogenesis.

=Treatment= is usually successful if the various etiologic factors are eradicated. Early treatment is very important. If the disorder is of more than local significance change the entire daily regimen of the patient. Diet, outdoor exercise and sufficient sleep should be

definitely regulated. A certain amount of general treatment to improve digestion, assimilation and elimination is imperative. An unbalanced diet and over eating must be corrected. In certain moist types, eliminating fatty foods will be helpful, while in dry forms the starches and sugars should be reduced.

If there is an underlying disease this should be remedied if possible. Particular attention should be paid to constipation.

Common sense in diet, rest, change of environment and free elimination, coupled with due attention to the osteopathic lesions, will cure the vast majority of cases. The greatest difficulty arises where there is some underlying disease. The parts should be protected against irritation such as dirt, cold, soap, and too much water. Meddlesome local treatment is to be guarded against. A simple application is boric acid, rice-flour or cornstarch, or where there is much itching add carbolic acid to the saturated solution of boric acid. Substitute bran for soap for cleansing purposes.

=Herpes Simplex=, fever-blister, or “cold sore” comprise two principal varieties: =herpes facialis= and =herpes genitalis=. The first occurs upon or near the lips, face, neck or ears. When the herpes is on the tongue or the mucous membrane within the mouth it is commonly termed “canker sores.”

Herpes genitalis is located on the prepuce, glans penis or farther back upon the penis. In the female the labia majora and minora and vestibule are the usual locations. Lack of cleanliness, sexual excitement and adherent prepuce are causative factors, though predisposing factors such as faulty circulation and disturbed innervation are to be considered.

In “cold sores” there is often some gastro-intestinal disturbance, especially intestinal stasis, cold in the head and other infections that supply toxins which irritate the nerves. No doubt there are underlying osteopathic lesions that lower the local nerve resistance or block the impulses such as vertebral and inferior maxillary lesions. The predisposing disturbance is probably due to the Gasserian ganglion.

Cold winds and excessive exposure to the sun’s rays will effect the tissues over the mental and infraorbital foramina, tensing the muscles and irritating the nerves at these points. On palpation they will be found sensitive. Frequent rotary motion by tip of finger over foramina will open them and allow congestion to drain.

=Herpes Zoster=, or shingles, is an acute inflammatory disease characterized by groups of small vesicles, usually along the course of the intercostal nerves on one side of the body. Before the vesicles appear there is more or less severe neuralgia. The eruption is unilateral, very rarely bilateral. The nearby lymphatics are usually enlarged.

Though the intercostal nerves are the ones most frequently involved, still the lumbar, thigh, trifacial and other cutaneous nerves may be affected.

The most common lesion is an inflammation of the posterior spinal ganglion which usually involves the fibers of the entire nerve. Inflammation of the nerve outside of the ganglion will cause the disorder. Toxins from various infectious sources are often exciting causes. Vertebral and rib lesions are always found; and where the Gasserian ganglion is involved lesions of the inferior maxilla and upper cervical vertebræ are predisposing factors. Thus osteopathic lesions from traumatism, cold and wet, and imbalance of muscular tension are important. Exudates, tumors, pleuritic and pulmonary affections are to be considered as possible sources.

=Treatment.=—Adjust vertebral lesions and carefully raise and separate ribs if intercostals are affected. Look after vertebral origin of any other nerve or nerves if otherwise. Local application of talcum or starch or boric acid will generally be sufficient.

=Urticaria=, hives or nettle rash is a common affection often due to some derangement of the digestive tract. This may be a mechanical irritation or of a toxic nature. Every one is familiar with the various foods that are apt to cause the hives, shell fish, strawberries, cheese, pork, oatmeal, mushrooms, etc.

The irritation may be a reflex one from the visceral disturbance; also, there may be irritation of the pelvic organs that would give rise to the trouble. It is well known that certain drugs will produce urticarial eruptions. There are cases where the irritation is simply local due to the nettle, mosquito bites and wasp stings.

In chronic cases intestinal stasis, nervous exhaustion and nephritic diseases are important.

No doubt osteopathic lesions frequently determine the location of the wheals. These lesions affect the innervation and thus establish a basis for the reflex vasomotor effect. This is in the nature of spasm of the cutaneous vessels quickly followed by dilatation with exudation of serum. The irritant probably acts on the walls of the blood vessels.

=Treatment= consists of thoroughly emptying the bowels by warm water enema, correcting the diet, toning the viscera and adjusting the osteopathic lesions. Thorough attention to the patient's environment, daily habits and occupation are of value. Warm soda baths will relieve the itching.

=Acne= is a common skin disorder that is characterized by an inflammation of the sebaceous glands of the nature of papules, tubercles or pustules. The face, shoulders, chest and back are the regions usually involved. It generally, appears about puberty. Blackheads is the starting point; these are accompanied with greasy skin and dust, and influenced by micro-organisms and more or less intestinal disorder.

The general or systemic health no doubt affects the local disorder, as in many skin diseases; for various intestinal derangements as indigestion, constipation, etc.; pelvic and menstrual irregularities; general ill health; anemia, etc. affect circulatory, glandular and nervous integrity. Any disturbance of normal elimination is important.

The =treatment= consists of careful attention to the general health and to the local innervation of the face or region involved. Measures that tone the bodily organs such as outdoor life, regular habits, plenty of sleep and correct diet are important. In some cases the X-ray is of value.

ANIMAL PARASITES

Tape Worms

=Varieties.=—Taenia solium; taenia saginata; bothriocephalus latus.

The larvæ of tape-worms are introduced into the intestinal canal by food and drink. The parasite reaches adult growth in the intestines. The larval forms are then found again in the muscles and solid organs.

=Taenia Solium.=—This is derived from the hog, and is the most common form in this country. When mature it is from two to four yards in length. The head is small, about the size of a pin, and provided with four cup-like suckers surrounded by a double row of hooklets, hence it is called the armed tape-worm. The head is fastened to the body by a thread-like neck, and following the neck, the body occurs in segments. The sexual organs, both male and female, occur in the center of the broad surface of the segment. The segments are about one millimeter in length and seven or eight millimeters in breadth. There are thousands of ova in each mature segment. The worm attains its growth in about twelve to fifteen weeks, after which time the segments are shed and passed. For further development the ova must gain entrance to the stomach of a pig or of man, and passing from the stomach they may reach the muscles and organs and develop into larvæ or cysticerci.

=Taenia Saginata.=—This is derived from beef, and is much longer and larger than the taenia solium. It is from five to six yards in length; the head is over two millimeters in breadth, is square shaped, and has four large sucking discs, without hooklets; hence it is called the unarmed tape-worm, in contra-distinction to the hooked variety. The segments are thicker and the ova larger, and they are passed and ingested in the same manner as the taenia solium.

=Bothriocephalus Latus.=—This is found especially in Europe and is very long, measuring from eight to ten yards; it is derived from fish, is not provided with hooklets, but has two lateral grooves. The segments are short and wide, the sexual organs being on the narrow side of the segment.

=Etiology.=—Unhealthy condition of the stomach and intestines is the predisposing, and uncleanliness an important, factor in the occurrence of tape-worm. Those eating imperfectly cooked beef, pork, fish or other meats, and those handling fresh meats, are liable to be affected with tape-worm.

When the ovum is taken into the stomach the capsule is dissolved and the embryo passes into the small intestines, fastening itself into the mucous membrane, by its hooklets and suckers and grooves.

=Symptoms.=—Tape-worms occur in the human being at all ages. Oftentimes symptoms are absent, the expulsion of segments being noticed and thus the worms accidentally discovered. The tape-worm is seldom dangerous, but if a worm is known to exist it is always a source of considerable anxiety on the part of the patient. Severe anemia may result and be wrongly diagnosed.

There are dyspeptic symptoms, colicky pains, nausea and occasionally diarrhea. The appetite is variable, sometimes ravenous. This condition is followed by loss of flesh and various reflex phenomena, as vertigo, headache, convulsions, palpitation, choreic

movements, itching of the nose and anus, paralysis, and rarely, insanity. In addition to these symptoms there may be a wrinkled countenance, sensation of a cold stream winding itself toward the back immediately after a meal, pain in various parts of the body and ringing in the ears. The decisive diagnostic symptom is to find segments of the worm in the stools.

=Diagnosis.=—Discovery of the ova or segments in the passages of the bowels is the only proof of the presence of a tape-worm.

=Prognosis.=—Favorable in all cases.

=Treatment.=—Prophylactic treatment is necessary. Meats should be thoroughly cooked so that the larvæ will be destroyed; and all segments of tape-worms passed in the stools should be burned—by no means should they be thrown outside or in the water-closet.

The immediate expulsion of a tape-worm is not a necessity. First of all the mode of living, and then the general state of health should be corrected. Tape-worms invariably result from a general state of unhealthiness, and with improved health and corrected digestive processes the worms cannot exist, and in a short time will be expelled. Expulsion of the head is necessary before the case will be cured, for if the head is not expelled new segments will continue to grow.

Stimulating the liver to increase the amount of bile, and increasing the activity of the digestive glands of the stomach and intestines, by a thorough treatment of the splanchnic region and direct treatment over the abdomen, will usually be sufficient for the cure of intestinal parasites. The treatment will probably have to be repeated several times, in order that the intestines may regain a healthy tone, so that the parasite will not find favorable conditions for its existence within the intestines, and that the bile may be secreted in sufficient quantities to dislodge the worm.

Hahnemann claimed, “that during a period of comparative health tape-worms do not inhabit the intestines proper, but rather the remnants of food and fecal matter contained in the intestines, living quietly as in a world of their own without the least inconvenience to the patient and finding their sustenance in the contents of the bowels. During this state they do not come in contact with intestinal walls, and remain harmless. But when from any cause a person is attacked by an acute disease the contents of the bowels become offensive to the parasite, which in its writhing and distress touches and irritates the sensitive intestinal lining, thus increasing the complaints of the patient considerably by a peculiar kind of cramp-like colic. (In similar manner the human foetus in the womb becomes restless, twists its body and moves whenever the mother is sick, but floats quietly in the liquor amnii, without distressing her while she is well.)” This but harmonizes with the osteopathic theory and practice with regard to tape-worm, that there is an unhealthy condition of the intestines which predisposes to the affection, and consequently the cure must be a correction of such a disordered state.

During the treatment, if a light diet of milk and broths is given, it will favor an earlier removal of the parasite, by helping to remove the mucus in which the head is embedded. If this fails extract of male fern is suggested.

Ascaris Lumbricoides (Round Worm)

This is the most common parasite, and is found principally in children; it is also found in cattle and hogs. It is of a yellowish brown color and in form resembles earth worms. The worm is cylindrical, pointed at both ends; the female is from seven to twelve inches in length, and the male from four to eight inches. They are probably introduced into the stomach by food and drink. They occupy the upper part of the small intestine, and are usually one or two in number, though they may be numerous. Occasionally they migrate into the stomach and are ejected by vomiting, or into the trachea and produce suffocation, or into the larynx or Eustachian tube, or they may pass downward to the anus, or into the bile ducts.

=Symptoms.=—Oftentimes symptoms are absent. There may be dyspepsia, colicky pains, mucous stools, meteorism, vertigo, fretfulness, voracious appetite, anemia, sallow complexion, headache, chorea and convulsions. Other symptoms may be present, as grinding of the teeth and itching of the nose and anus. Obstruction of the bowels has occurred. If a worm enters the bile duct obstructive jaundice occurs. A decisive diagnosis can be given only when the worm is seen.

=Treatment.=—Particular attention should be paid the liver, for it is here that we must seek the natural remedy in the form of bile, in order to eject and cleanse the system from nematodes.

Modes of improper living should be corrected; cleanliness is essential, and there should be attention to the general health of the patient. Thorough correction of all defects of the spinal column in the region of the splanchnics, and careful direct treatment of the bowels is indicated. The child may be put to bed and fasted twenty-four hours, then the liver strongly stimulated to increase flow of

bile.

If the above treatment is not successful oil of wormwood may be employed.

Oxyuris Vermicularis

(Thread-worm; Pin-worm)

This small parasite, commonly seen in children, is from three to five millimeters long in the male and about twenty millimeters in the female, is blunt at one end and sharp at the other, and occupies the colon and rectum. They are probably introduced into the intestines in the ova, by uncooked fruits and vegetables, or by the dirty hands of mothers and nurses of the infants. They vary greatly in number; migrate to the rectum where they deposit their eggs, and are often discharged in the feces, where they appear like pieces of ordinary white thread.

=Symptoms.=—Loss of appetite, anemia, restlessness and irritability are marked. The itching becomes intolerable when the worms come down in the rectum to the anus and within the folds about the anal orifice. In the female the worms may wander into the vagina where they become particularly distressing, and thus may produce excessive sexual excitement and cause nymphomania and masturbation.

=Treatment.=—Cleanliness of the most scrupulous kind should be demanded in every instance. Injections of cold salt water (repeated for at least ten days) and other agents within the rectum will destroy the eggs as soon as they are deposited, besides relieving the terrible itching. In obstinate cases use quassia decoction.

Attention to the general health of the patient and great care of the intestines and other digestive organs are absolutely necessary. The spinal treatment to the intestines and other digestive organs, as well as thorough direct treatment over the abdomen, is indicated.

Uncinariasis

(European hook-worm disease; Miner's anemia; Ankylostomiasis; Hook-worm disease)

This disease results from infection by the hook-worm of any of the various types. In Europe it is found in Italy, Belgium, Germany, France and Switzerland. In America it seems to be of Africo-Asiatic origin but was first discovered in the Southern states and abounds chiefly in Texas, Florida, Georgia, North and South Carolina as well as in the West Indies. Infection comes from unprotected feces that are allowed to be spread where the feet or hands may come in contact as it is without doubt that the contagion occurs through the skin. One authority states that hook-worm is rarely found except in cases where ground itch has occurred within a period of eight years. Negroes harbor the parasite and transmit it but seem immune to its effects while the poorer whites are afflicted to a large degree. The worms are carried from some abrasion of the skin, by the blood to the heart and lungs, thence to the pharynx and swallowed, thence to the duodenum and jejunum where they attach themselves to the lining walls. Here they not only feed upon the blood but develop a toxin. The female worm is about twice the size of the male, 10 to 18 mm. as against 6 to 11 mm. and there is slight difference between the old and new world varieties. The head is provided with four hook shaped teeth which form the attachment to the intestine and it is very secure.

=Diagnosis.=—For years the languid, dull, expressionless, lack-luster of eye and general unambitious characteristics of the inhabitants of the great sand belt of the United States attracted attention and was attributed to laziness but the discovery of the hook-worm explained the cause. Children are stunted in mind and body and have a muddy, dirty white complexion.

At the beginning there must be a very considerable colony of the parasites to cause symptoms but as the disease advances there is a distention of the abdomen from enlargement of the spleen and liver and from flatulency. There is palpitation, shortness of breath, cardiac bruits from the severe anemia while edema of the feet and legs is rather common. The blood shows a severe secondary anemia with its coagulation time much increased. Leucocytosis is not common; hemoglobin is from one-tenth to one-half normal with erythrocytes about half normal.

=Treatment.=—The removal of the worms with the least possible harm to the body is indicated. Thymol is a poison which is not absorbed by the body, when carefully given, and which is very toxic to the parasite. The dose varies from eight grains for a child under five years of age, to forty-five for an adult. Thymol is soluble in fats and in alcohol, so that for a day or so before the thymol is given, and from one to four days after, no fats or alcohol should be taken. The best way to avoid poisoning by thymol is to give the

patient charcoal, then no fats or alcohol is permitted until the treatment is completed. When the stools become black, the thymol is given on an empty stomach. A purgative is given a few hours later. Enemas should be used very freely in order to facilitate the removal of the injured or poisoned worms. Another dose of charcoal is given, and when the stools are black again, the patient may return to his ordinary diet. The denial of fats to the person so thoroughly accustomed to bacon three times a day is a factor met with difficulty in dealing with patients of the ordinary class with the disease. (Clinical Osteopathy.)

=Prophylaxis.=—After treatment it is imperative to prevent reinfection and to do that the most rigorous sanitary measures must be instituted. All feces must be disposed of and habits of cleanliness in defecation insisted upon while negroes, who harbor the worm without showing symptoms, must be looked after as well as the actual victims. Care of the feet is important and shoes should be worn in infected regions and all abrasions of the skin protected. Drinking water must be uncontaminated which presents a problem as wells and springs are usually unprotected. Absolute and persistent cleanliness is the answer to the question of prevention.

Trichiniasis

Trichiniasis is a name given to a disease produced by the embryos of the trichina spiralis. In the adult condition the trichina spiralis lives in the small intestines. The embryos migrate into the muscles where they finally become encapsulated. Man is infected by eating insufficiently cooked pork containing the encapsulated worm, which is set free during the digestive process. About the third day they attain their full growth and become sexually mature. Each one discharges large numbers of embryos. As soon as born the young brood is carried away from the bowel and invade the muscles through various channels—principally by means of the blood stream and along the connective tissue routes. The female trichina may bring forth several broods of embryos in succession. In nine or ten days after infection the first brood reaches its destination. They attain to maturity in about two weeks after entering the muscular tissue. In this process an interstitial myositis is excited and a fibrous capsule is formed in four to six weeks. The capsule gradually becomes thicker and finally calcareous infiltration may take place.

Thorough cooking destroys the parasite. The disease is most frequent among the Germans who eat raw ham and sausages.

=Symptoms.=—These are sometimes absent, especially when only a few are eaten. If large numbers have been ingested, gastro-intestinal symptoms develop in the course of a few days. Vomiting, diarrhea, and pain in the abdomen may be present.

In from one to two weeks muscular symptoms develop. There is fever, muscular pain, especially during motion, and the muscles are stiff, tense and sometimes swollen. When the respiratory muscles are involved dyspnea is produced, which may prove fatal. Eosinophilia is a helpful diagnostic point. Edema, especially of the face, is an important symptom. Profuse sweats, itching and tingling of the skin have been observed.

=Diagnosis.=—Epidemics of this disease are more easily diagnosed than an isolated case. Among the Germans, if cases of apparent typhoid fever occur after a picnic or other feasting occasion, where raw ham or sausages have been indulged in, this disease should be suspected. Examination of the stools and of the muscles will be of aid. The worms may be discovered in the pork, a portion of which has been eaten by the patient.

=Prognosis.=—This depends upon the number of worms ingested. The prognosis should always be guarded. Early, marked diarrhea is favorable.

=Treatment.=—Prophylactic treatment is of great importance in trichiniasis. Inspection of the meat supply, is doing much to prevent trichiniasis; although the most practical way to prevent the disease is to thoroughly cook all pork and sausages. The central portions of the meat should be well cooked.

In the feeding of hogs care should be taken that they do not receive any offal, but only milk, grain, vegetables, etc.

When a person is infected with trichiniasis, thorough and prompt evacuation of the bowels should be performed at once, so that the embryos will not have time to pass into the muscles, but will be ejected from the body. This should be followed by a thorough and persistent treatment for several days of the liver and intestines; treat both the liver and intestines directly and through the spine. The object of this treatment is to render all the digestive juices active, so that they may dislodge the animal parasite, and to prevent their passing into the muscles. Also keep the bowels active for several days.

When the larval parasites have entered the muscles, a treatment cannot be applied to affect them directly, but the health of the body should be maintained if possible, and the severer symptoms, as the muscular pains, weakness and insomnia combated. Thorough manipulation, massage and hot baths will be of special aid in relieving the stiffness and weakness of the muscles.

Filaria

(Filaria Sanguinis-Hominis)

There are two varieties. One is a thread-like worm with tapering, blunt ends, appearing in the blood at night, hence called =nocturna=, while the other is of slightly different form, appearing in the blood only by day and is called =diurna=.

The mosquito is the communicating host of the parasite. During the night, or should the patient sleep during the day, the =nocturna= appears in the peripheral circulation, while during the other interval they are probably in the other vessels, particularly the lungs.

After the mosquito has taken blood from an affected patient it requires from six to seven days for the metamorphosis of the minute filaria which are then lodged in the probosis of the mosquito and introduced into the blood of the next victim. The adult parasite is from three to four inches long and the thickness of a coarse hair, with clear sexual distinction.

=Pathologically= there are no distinct lesions, as the parent worm must establish one. Lymphatic engorgement may result from plugging of the thoracic duct or of a large lymphatic with consequent engorgement which may develop symptoms in the inguinal glands, pelvic and lumbar lymphatic trunks. As these varicosities develop rupture may occur; if into the genito-urinary tract chyluria or chylocele may result, or if in the abdominal cavity chylous ascites.

Lymphangitis follows a lymph stasis, which later results in =elephantiasis=. (Barbadoes leg.)

=Symptoms.=—Elephantiasis affects the legs, but the arms rarely; the labia of the female and scrotum of the male; occasionally the breasts and other parts of the body. Fever is present on account of the lymphangitis, accompanied by rigors and delirium and there is marked local inflammation. The attack terminates in a pronounced sweat. In deeper parts there is deep seated pain and signs of sepsis, while abscesses may develop over the inflamed area.

The varicose inguinal glands are doughy, soft and painless, with both sides affected alike. The scrotum is affected by the extension, and at times the testes.

=Treatment= is surgical, as the tumors must be removed. Unless the female worm is also removed this is, however, only palliative.

Methylene blue is said to be destructive to the filaria and it is practically harmless to the human body. The only treatment is one that will aid in building up the general health.

HEMORRHAGES

Nasal Hemorrhage

(Nose bleed; Epistaxis)

=Osteopathic Etiology= and =Pathology=.—Traumatism, such as picking the nose, blows, and surgical operations; straining when coughing; nasal tumors and ulcerations; lesions of the atlas, or any lesion of the upper cervical vertebræ, that would interfere with the vasomotor distribution to the nose and cause local congestion or weakness of the blood vessels; obstructions to the general circulation; irregularities or suppression of the menstrual flow may result in nose bleed, as a vicarious menstruation; suppression of a habitual hemorrhoidal discharge.

=Pathologically= the great frequency of nasal hemorrhage is due to the great vascularity of the nasal mucous membrane. Usually in cases of spontaneous origin, bleeding is from the region of the septal artery. Spontaneous bleeding may also occur from posterior hypertrophies or adenoid vegetations. The blood flowing downward into the fauces, is expectorated in such cases, and may be mistaken for a hemorrhage from the lungs.

=Treatment.=—The position of the individual is important. He should assume a sitting posture, or as nearly so as possible. Holding the nostrils tightly, or plugging them with a piece of cotton, will favor the formation and retention of a clot, so that the hemorrhage may be controlled. Pressure upon the carotid artery, or upon the facial artery at the angle of the inferior maxilla, will slow the blood current and favor the formation of a clot, also pressure on the sides of the bridge of the nose may influence it. Correcting any lesions that may exist in the superior cervical region, as derangement of the vertebræ or contracted muscles, will remove

obstructions or irritations to the vasomotor system of the affected region, and thus equalize the vascular system. Holding the arms above the head, and the application of ice to the nose are of aid in some cases. Also, injection of cold or hot water into the nostrils. In serious and obstinate cases, where other methods fail, a plugging of the anterior and posterior nares should be resorted to, using absorbent cotton or gauze.

Broncho-pulmonary Hemorrhage

(Hemoptysis)

=Osteopathic Etiology= and =Pathology=.—Pulmonary congestion; croupous pneumonia; tuberculosis; hemorrhagic infarction; ulcers of the larynx, trachea or bronchi; gangrene of the lung; fibrinous bronchitis, carcinoma of the lung; lesions of the ribs or vertebræ from the second to the seventh dorsal inclusive, may cause diseases of the bronchial tubes or lungs, that result in hemoptysis, or the hemorrhage may be caused directly by extreme congestion resulting from the disordered vasomotor nerves; diseases of the heart, such as mitral disease, causing pulmonary congestion; aneurism of the branches of the pulmonary artery; vicarious menstruation from deranged menstrual functions; diseases of the vessel walls, or blood, as scurvy, anemia, hemophilia, etc.

=Pathologically= in many cases, the lesions are microscopic, consisting of ruptured capillaries. In other cases larger vessels may be ruptured, or are the seat of erosion. Many other lesions may be observed. After death the bronchial mucosa is occasionally found inflamed and the lung tissues paler than normal.

=Diagnosis.=—A differential diagnosis must be made between epistaxis, hemoptysis and hematemesis.

In =epistaxis= the blood may flow from the posterior nares into the pharynx; it causes coughing and a discharge of the blood may occur the same as in hemoptysis. A careful examination of the nasal region alone can determine the source of the bleeding.

In =hemoptysis= the history of the case as to pulmonary or cardiac diseases is to be considered. There is a feeling of weight and of uneasiness in the chest. A salty taste and a tickling of the throat precedes the bleeding. The blood is ejected by coughing and is bright red, frothy, very little coagula, and is alkaline in reaction.

In =hematemesis= the history would indicate disease of the stomach, spleen, liver or heart. Uneasiness, and occasionally nausea and faintness, precedes the bleeding. The blood is ejected by vomiting, and is dark, clotted or fluid, mixed with food, and is of acid reaction. In a few instances the blood due to hemoptysis may be swallowed, and vomited.

=Treatment.=—In all these cases of hemoptysis the patient should be placed in bed and absolute rest demanded. An attempt should at once be made to correct any lesion that may be found influencing the cause of the bleeding. Correcting lesions to the vasomotor nerves of the lungs and bronchial tubes, and equalizing the disturbed vascular area, may be sufficient in a number of cases. These lesions will be found principally in the upper dorsal region. In some cases, perhaps, there is an impairment of the trophic nerves by the same lesions, thus interfering with the tone of the vessel walls and pulmonary tissues. The diet should be light, nutritious and non-stimulating. The use of hot drinks is to be avoided. The rapidity of the heart's action should be reduced. This is best performed by thorough treatment of the dorsal spinal nerves of the left side over the heart, and by inhibition in the suboccipital region. The ice-bag to the precordia is also helpful. Iced drinks and the eating of ice is of aid. Stimulation of the systemic circulation will be of value in helping to relieve the pulmonary congestion, although the two systems are somewhat independent of each other. Also, hot foot baths and the evacuation of the bowels may be of additional value. In cases due to organic disease of the heart, the mind and body should receive absolute rest, so that the diseased areas may be strengthened as much as possible; besides a tonic treatment for the heart's action is necessary.

After the hemorrhage has subsided care should be taken that bleeding does not occur again. All irritations of the respiratory tract should be avoided. A stimulating diet, tobacco and alcohol should be avoided. Nutritious food and a moderate amount of exercise is indicated.

Hemorrhage of the Stomach

(Hematemesis)

=Osteopathic Etiology.=—Injuries to the stomach; local diseases, as congestion, ulcers and cancer; vicarious menstruation; a mechanical obstruction to the portal circulation; spinal lesions to the vasomotor nerves of the stomach; alterations in the blood;

perforation of the stomach walls, involving a blood vessel; disease of some neighboring organ.

=Diagnosis.=—A careful examination of the case and of the blood ejected will be necessary to determine the nature of the cause. The differential diagnosis as to the source of the blood, whether from the stomach or lungs, was given under hemoptysis.

=Treatment.=—Correction of any lesions that may influence the blood pressure in the region of the stomach, is the first requisite. Treatment of the splanchnics has the greatest influence upon the vasomotor nerves to the stomach. Treatment of the vagi nerves and of the fourth and fifth dorsals, will quiet the violent movements of the stomach, and thus aid in controlling the hemorrhage. Stimulation of the cervical sympathetics and heat applied to the feet will tend to equalize the vascular system, and thus lessen the gastric congestion. The application of a broad flat ice-bag over the stomach will be of great value. Keep the patient quiet in bed. Surgical interference may be necessary.

Intestinal Hemorrhage

=Osteopathic Etiology.=—An obstructed circulation of the blood through the venaporta, as in diseases of the heart, lungs and liver; lesions of the vertebræ deranging spinal nerves to the intestinal blood supply; injuries caused by corroding or cutting substances; mechanical injuries to the intestines; degeneration or erosions of the blood-vessels from ulcers of the intestines, as from typhoid fever, typhus, dysentery, etc.; disordered menstrual or hemorrhoidal discharges.

=Diagnosis.=—The locality of the intestines affected can be approximately determined by an examination of the discharged blood. When the blood comes from the upper part of the intestines, it is generally dark and mixed with the intestinal contents, which gives it a tarry appearance. It is generally red and fluid when it comes from the lower portion of the bowels. If from the stomach, the blood is thoroughly mixed with fecal matter. Throwing the passage into water, the water is colored red when it contains blood, and if the contents contain bile the water is colored green or yellow. Also, noting the areas of contracted muscles, as in intestinal colic, will aid in the regional diagnosis.

=Treatment.=—Absolute rest in all cases is necessary, the patient remaining as quiet as possible. Food, in severe cases, should not be given for ten or twelve hours. The bed-pan should be used in caring for the evacuations. Correction of the lesions along the spinal region, chiefly of the lower dorsal and lumbar regions, that are impeding the innervation to the intestines, should be attended to at once. This treatment tends to relieve any hyperemic condition of the intestinal mucosa and influences the whole vasomotor area of the mesentery. Direct treatment of the abdomen in a few cases is of great value to relieve obstructed and contracted vessels in the mesentery, but in certain pathological conditions, e. g., typhoid fever, leave the abdomen alone. Treatment (inhibition) along the spinal column from the sixth dorsal to the coccyx is helpful in all cases to quiet the peristalsis of the intestines. In severe cases cold drinks, eating of ice and an ice pack to the abdomen are of aid. In a few instances surgical measures will be necessary.

Hematuria

=Osteopathic Etiology.=—Congestion and acute inflammation of the kidneys, exacerbations of pyelitis, renal calculi, chronic nephritis, traumatism, tuberculosis, etc.; affections of the urinary tract, as calculi or lacerations of the ureter; calculi, cystitis, ulcerations, etc., of the bladder; calculi, gonorrhoea, parasites, etc., of the urethra; general diseases, chiefly the acute specific fevers and blood diseases; blows, wounds and traumatic influences, external to the kidneys; lesions of the renal splanchnics.

=Diagnosis= of the locality of the hemorrhage in the urinary tract: In hemorrhage from the =kidney= the blood is thoroughly mixed with the urine, giving a uniform color. Blood casts and leucocytes are present. In hemorrhage from the =ureters= the blood is usually molded in clots which conform to the shape of the ureter. The clots appear like small dark worms. In hemorrhage from the =bladder= the blood is not thoroughly mixed with the urine and large clots form upon standing. In hemorrhage from the =urethra= the blood often discharges without micturition. When urine is passed the blood precedes the passage of urine.

=Treatment.=—Rest is essential. A correction of the lesions to the renal splanchnics is necessary to control the congestion and inflammation of the kidneys. When the ureters, bladder or urethra is involved, attention must be given to the condition of the spinal column below the renal splanchnics. In all cases the inhibitory treatment to the lower spinal column and ice to the loins are of value. If surgery is indicated, do not delay operation.

Uterine Hemorrhage

Most of the causes of uterine hemorrhage come under the subject of obstetrics; others under menorrhagia and metrorrhagia. Such will be found in obstetrical and gynecological works.

=Treatment.=—The patient should assume the dorsal position with the buttocks raised. If any displacement of the uterus is present or if there is any foreign material in the uterus, usually such should be corrected or removed at once. Stimulation of the clitoris is a most effectual means to control uterine hemorrhage; it contracts the circular fibres of the uterus. Stimulation of the uterus directly through the vagina, and over the abdomen, and stimulation of the upper wall of the vagina, will aid in contracting the uterus. A quick, unexpected pull of the hair on the mons veneris will have the effect of closing the capillaries by shock to the nervous control (Dr. Still). Before closing the os, however, it is well to know that there is no irritating foreign material within the body of the uterus. Correction of obstructions of the vasomotor nerves of the uterus through the splanchnic and lumbar region is important. Compression of the abdominal aorta, and vaginal injections of hot water may be of aid, as will also a hot water bag at the lumbar region and ice water bag over symphysis. In severe cases inversion of the body, if it can be done with safety, may be performed. Packing the vagina is a method resorted to occasionally in severe cases.

Hiccoughs

Occasionally there is a case of hiccoughs that has been continuous for hours or even days and that all efforts have failed to stop. They are caused by an irritation to the peripheral distribution of the phrenic nerve from some gastric disturbance or a local irritant acting upon the center in the medulla. It may follow fright or great emotion and be associated in persistent form in rheumatism, typhoid fever and other febrile diseases. It follows abdominal operations at times and is very distressing. When occurring in elderly people with pneumonia and in peritonitis with distention it usually marks the end. The same may be said in case of carcinoma of the stomach and bowels.

=Treatment.=—Go first to the origin of the phrenic nerve at the third, fourth and fifth cervical and, if there is a lesion as there will probably be, adjust it and note results. This will be sufficient in many cases. Failing, bring direct pressure on the nerve just above the clavicle and anterior to the sternomastoid muscle and release the scaleni muscles. After this examine and treat at the fifth and twelfth dorsals. Correct any lesions but best results will be had from inhibition at these points. Another method is to stand beside the patient and insert the fingers of both hands under the costal end of the ribs and lightly pull. Firm pressure over the solar plexus with flat of the hand is sometimes beneficial. In hysterical cases, drawing out the tongue will often be effective and it has been suggested that standing the patient on the head will stop them in short order. Tickling the nose to produce violent sneezing is an ancient remedy. Some one of these will cure the case, as osteopathy has never failed so far as recorded.

The stomach should be emptied of all irritating matter to prevent recurrence.

VARICOSE VEINS

In varicose veins there is a dilatation of the calibre of the veins and their valves are insufficient. The walls are irregularly thinned, lengthened and tortuous.

=Osteopathic Etiology= and =Pathology=.—The =internal saphenous= is the vein most frequently affected, although any vein throughout the body may become varicose. Commonly, varicose veins occur in the lower extremities and occasionally in the arms.

The =valvular insufficiency= is caused by stretching of the wall of the vein, thus separating the thin, free edges and leaving an interspace that allows regurgitation of the blood. The valves becoming insufficient, the column of blood in the veins has no support against gravity, and being interrupted in its course does not flow normally into collateral channels. The walls of the veins become thin, as does also the adjacent skin, thus increasing the danger of a rupture, either external or subcutaneous.

Varicose veins are most frequently found in females, following uterine enlargements. The condition may be due to any obstruction or constriction that prevents the free return of blood from the veins, such as dislocations of the hip, either slight or complete, dislocations of innominata, contractions of adductor magnus muscle affecting femoral vein, prolapse of diaphragm obstructing vena cava, tissue constrictions about the saphenous opening, garters, and, in fact, anything that might impede the free venous flow. The tendency to varicose veins increases as age advances, and many cases are found among people of middle life who have been accustomed to standing a great deal. Injuries to the pelvis, thigh or leg, lessening the nutrition to the leg, or injuries to the nerves, as vertebral dislocations in the lower dorsal or lumbar regions (the fourth lumbar especially) may be causes of varicose veins. Pregnancy or tumors in the abdomen or pelvis, causing pressure upon the iliac veins, are occasionally causes. Distention of the

sigmoid flexure, causing pressure upon the left iliac vein, or distention of the cecum; pressing upon the right iliac vein, are fruitful sources, as are also diseases of the heart and lungs. Varicose veins of the upper extremities are due to occupations requiring overuse of the arms.

=Complications.=—Varicocele, hemorrhoids, labial varix in the female, varix over pubes, ulceration and eczema due to disturbances of nutrition, edema and thrombus.

=Symptoms.=—=Lower Extremities.=—Cramping pains in the limbs upon rising. Fullness and heaviness of the limbs. Inspection may reveal superficial varicose veins near the saphenous opening, upon the external thigh, in the popliteal space, upon the external leg or behind the ankles. Edema and congestion of the foot and ankles occur in a few cases. Pain is quite a prominent symptom, due to pressure upon the nerve fibres. Eczema and itching are due to disturbed innervation and blood supply to the skin. Ulceration may occur, due to the bursting of a vein.

=Upper Extremities.=—Before the varicosity appears there is usually pain or a feeling as of a sprain in the involved region of the arm. The pain is usually confined to a muscle or group of muscles.

=Treatment.=—The majority of cases are due to disorders about the pelvis, hip or thigh, and the treatment resolves itself into the removal of these obstructions or constrictions. Occasionally cases are caused by partial dislocations of the hip joint, which can be easily overlooked during a hurried examination. The slipping of an innominatum is an important factor. Rest in a recumbent position, attention to the general health, and especial attention to the bowels and liver, are essential in acute attacks. Occasionally the heart and lungs are at fault. Treatment twice per week should consist of removing any of the numerous causes of the condition, and spinal treatment as well; then the leg should receive special attention. Remember, thrombi may form and the vein must, under no circumstances, be touched in the treatment. Begin by carefully rotating the leg to stretch contracted tissue about the saphenous opening, then separate the tendons of the popliteal space and follow the course of the vein to the abdomen and relax tissue about it. Keep patient off the feet as much as possible and elevate the leg when sitting.

In rupture of varicose veins the hemorrhage can be arrested by elevating the limb and applying pressure with the fingers, above and below the wound, until a compress and bandage can be applied. The support of the varicose veins by elastic stockings will ease the pain and prevent edema in many cases, but, as a rule, it is a direct hindrance to the circulation on account of the necessity of having the stocking fit closely. Surgical operations are rarely indicated.

Phlebitis

(Phlegmasia alba dolens; milk leg)

An inflammation of a vein. In the condition described here it is a puerperal septic inflammation of the femoral vein. About the third week after confinement there is a swelling of the leg with or without redness. Great pain accompanies the condition and the temperature gradually rises to 102°-3°. As understood by osteopaths, this is the result of a partial closing of the saphenous opening during parturition so that the venous flow is partly stopped.

=Treatment= consists in carefully rotating the leg at the hip so that the fascia lata is spread, opening the lumen of the vein so the congestion will drain out. There will, also, probably be found innominate or lumbar lesions which must be adjusted with the result that almost immediate relief is given as a rule.

Chronic Phlebitis

The chronic form shows considerable inflammation along the line of the vein marked by tenderness, edema and thickening of tissue. The entire leg may be more or less involved through circulatory injury. In these cases will be found definite innominate lesions of a primary type or the distortion is superinduced by lumbar lesions. A few cases are quickly cleared up through adjustment that is readily secured. However, in others, there being considerable thickening of the sacro-iliac articulating tissues, some time may be required to get complete adjustment and consequent restoration of femoral circulation. In addition to this, careful abduction, flexion, hyperextension and circumduction is indicated. This last technique should be executed with great care and with due regard to pathology. If Dr. Still’s emphatic command were followed, that all maternity patients should have both legs rotated and innominates inspected, there would be no phlebitis cases, acute or chronic.

THE RECTUM

To treat the rectum intelligently and thoroughly, requires special knowledge on the part of the osteopath. A speculum should be used in many cases when making an examination, and all abnormal conditions carefully inspected with the eye; although much can usually be noted by the examination with the finger alone. The best position in which to give an examination and treatment is to have the patient on the side, with thighs flexed upon the abdomen. In a few cases the patient may lean over an operating table.

The =objects= of =rectal treatment= are many—to relieve hemorrhoids, etc., of the mucous membrane; to correct a dislocated coccyx; to treat an enlarged prostate gland; to replace a prolapsed rectum; to tone the lower bowel in cases of constipation; to give reflex stimuli to the heart and lungs, in cases of fainting, paroxysms, etc.; to relieve severe pains in the rectum at the time of the menstrual period, and to relieve congestion, inflammation, contracted tissues, etc., of local sources; to relax spasms in croup, and to remove tension to the nervous system in some forms of insomnia. In fact, so many diseases are affected by reflex irritations from the rectum that its examination is a necessity in many cases. The phrase “when in doubt treat the rectum” was coined by a progressive student and there is an element of truth in it. Surgical assistance to treatment will be considered under hemorrhoids.

The principal need of osteopathic internal rectal treatment, is: (1) To relax all contracted and constricted fibres about the walls of the rectum and between the sacrum and coccyx. (2) To correct a dislocated coccyx. (3) To dilate the sphincters thoroughly, in order to relieve irritations about the sphincters, and to stimulate the sympathetic nerves.

Work through the rectum to treat an enlarged prostate gland, to correct a displaced uterus, and to make a more thorough examination of the uterine tissues, the Fallopian tubes and the ovaries, is a frequent occurrence.

In giving =local treatment=, cleanse the fingers and oil the index finger; then, after introducing it into the rectum relax the contracted tissues by an upward sweeping motion on all sides. This treatment relieves all obstructions to vessels and nerves caused by contracted fibres, and tones the rectal walls. In prolapsed sigmoid, causing obstructive constipation, the finger can be used to separate the folds of mucous membrane and open the lumen of the bowel. Frequently there will be enough tone to the muscular coat so that the irritation will set up slight peristalsis and cause the bowel to draw up to a considerable degree. In children where there is much straining at the stool, the sigmoid will often be found down and by using the little finger the same results can be accomplished and much relief given.

To =dilate= and =stretch= the sphincters thoroughly a speculum or dilator should be used under anesthesia; still, considerable can be done by one or two fingers. The sphincter should be thoroughly stretched in all directions, care being taken when an instrument is used that too much force is not applied. Secure as much voluntary relaxation of the sphincter as possible. Inhibition at 2d and 3d sacral will aid. This treatment is of aid in cases of hemorrhoids and prolapse of the rectum, in constipation due to the loss of tonicity of the lower bowels, in tightness of the sphincters, in pain of the rectum, and in stimulating the heart and lungs. In cases of a prolapsed rectum, due to irritation about the sphincters, causing tenesmus, this treatment is of special value, as it gives the sphincter a physiological rest. Frequency of treatment per rectum must depend entirely on the patient and disease. It can be given daily in many cases and is frequently so indicated in acute hemorrhoids, prostatic troubles, etc.

According to Quain, the sensory nerves to the rectum are from the second, third and fourth sacrals. Some of the motor fibres of the circular muscles of the rectum are from the lower dorsal and upper two lumbar nerves; these pass by the aortic plexus to the inferior mesenteric ganglion. Associated with these fibres, are the inhibitory fibres of the longitudinal muscles of the rectum. The sacral nerves contain motor fibres to the longitudinal muscles, and inhibitory fibres to the circular muscles of the rectum. In all cases of rectal trouble, the lower dorsal and upper lumbar vertebræ may be found deranged, and thus interfere with the rectal nerves. Relaxation of the sacral muscles over the sacral foramina has a marked effect in relieving =tenesmus=. In dysentery, where there is a constant desire to defecate, a thorough upward relaxation of the sacral muscles will give great relief.

=Proctitis= or inflammation of the rectum is not an uncommon disorder. The disease has been divided into acute, chronic, gonorrheal, dysenteric, and diphtheritic. Foreign bodies, impacted feces, cold, purgatives, prolapse of the sigmoid, and lumbar, coccygeal and innominate lesions are the most important causative factors. The =acute= form is more frequently found in older people. The =symptoms= are tenesmus, frequent evacuations of blood and mucus (possibly pus), prolapse of the mucous membrane, feeling of fullness, and radiating pains. The gonorrheal, diphtheritic and dysenteric forms are of rare occurrence, with the exception that the dysenteric may be somewhat frequent. The =treatment= is to remove all local irritations, cleanse the bowels, and put the patient in bed. All irritating foods are to be prohibited. Use milk, soups, beef juice, soft boiled eggs and similar foods. Correct all osteopathic lesions; especially will inhibition over the sacral foramina relieve the tenesmus. Cold water in the rectum and applied to the anus will be beneficial. If abscesses occur, employ surgical measures.

=Prolapse= of the =rectum= is another common rectal disorder. Acute cases are especially found in children, due to straining at stool. The sacrum is more straight, and thus violent straining, coughing, etc., the more readily produces prolapse. Prolapse of the mucous membrane is the most common, although all of the rectal coats may be involved. Prolapse of the upper part of the rectum into the lower or invagination is frequently met with by osteopaths. The sigmoid may prolapse and also affect the rectum. The =treatment= is to return the mass, using an anesthetic if necessary. If it is not retained, place straps across the buttocks. Then with attention to lesions that may be disturbing and weakening the rectal walls, and thorough local toning treatment, the prognosis should be favorable. In high rectal prolapse local attention is necessary as well as deep treatment through the abdominal walls to the sigmoid and upper rectum. The use of Cole's irrigator for high enema will replace and elevate both the upper rectum and sigmoid and greatly aid in a cure. Regularity of habits and proper food are essentials.

Hemorrhoids

=Definition.=—A dilated or varicose condition of the plexus of veins lying in the submucous tissue of the lower part of the rectum. The dilatation of these hemorrhoidal veins may extend into the adjoining subcutaneous tissues and mucous membrane, and the perirectal plexus and adjoining venous plexuses of the bladder, uterus, vagina and sacral canal may become involved.

=Osteopathic Etiology= and =Pathology=.—The chief predisposing cause of piles is man's erect position and the absence of valves in the hemorrhoidal veins. Thus a retardation or stagnation of the portal vein would cause a backward movement of the entire column. It is evident that such a downward pressure of the blood in the portal system would dilate and extend the blood vessels, to the very capillaries in the rectal region.

This retardation may arise from several causes: obstruction of the portal vein, from diseases of the liver; diseases of the heart; obstruction or destruction of the capillaries of the lungs; pressure from a gravid uterus, tumor, etc.; a general loss of tonicity of the abdominal walls, as in persons who take but little exercise; the excessive use of wine, tea and coffee; injuries to the spinal column, especially in the lumbar, sacral and coccygeal regions; a dislocation of an innominate bone; lifting; constipation; straining at stool; carelessness of the calls of nature, etc. Catarrh of the bowels may cause a congestion of the mucous membrane and consequently piles. Hereditary influence may be a factor in a few cases.

Hemorrhoids are divided into two classes, =external= and =internal=. An =external pile= is one that arises from the margin of the anus outside of the external sphincter muscle. It differs from the internal pile from the fact that it is always composed either of skin or hypertrophied connective tissue, forming a mere cutaneous tag, or else it is composed of a small cutaneous vein enlarged by a clot of blood. The =internal hemorrhoids= are composed mostly of enlarged veins and are connected by hypertrophied connective tissue. They have a free arterial supply and are covered by the mucous membrane of the rectum. They are due, usually, to an affection of the middle hemorrhoidal blood supply, thereby being a part of the visceral vascular system. Internal hemorrhoids, when protruding, can be returned within the rectum, while the external ones cannot. The venous turgescence varies in size from a pea to a walnut. They may be single or may surround the entire anal opening like a bunch of grapes.

Repeated attacks of engorgement of the veins involved, will in time change the mucous membrane or the submucous tissue, and cause catarrhal swelling of the mucous membrane, or hyperplasia of the connective tissue. At first the hemorrhoid is usually a blood tumor, but in chronic cases it is oftentimes made up largely of connective tissue. Owing to pressure of the varicose veins, atrophy of the mucous and submucous tissue may occur. The white or slimy hemorrhoids occur when these roughened parts of the mucous membrane become inflamed and thickened, resulting in suppuration.

=Symptoms.=—The symptoms are quite diagnostic and need not be mistaken. Besides the appearance of tumors, there may be constipation, pain during stools, indigestion, headache and pain in the back. Hemorrhages frequently occur, and if suddenly checked, as by cold, other disturbances may occur, as congestion of the head, lungs, stomach, liver, kidneys, etc., which may result in hemorrhages from these organs. Fissures of the anus, contraction of the rectal sphincters and prolapse of the rectum may occur. Occasionally in old people there is a varicose state of the veins of the neck of the bladder, and in females, of the uterus and vagina, which causes hemorrhages of these organs. The communicating plexus of the spinal canal may be affected, causing weight, numbness and pain, so as to simulate a lesion of the cord. The patient may have a hypochondriacal disposition and be disinclined to work, especially at mental labor.

=Prognosis.=—Depends upon the predisposing and immediate causes, but a large majority of cases can be cured.

=Treatment.=—A thorough examination of the patient should be made, not only to ascertain the extent of the local trouble, but to understand thoroughly the general health of the sufferer, especially the state of the heart, lungs and liver.

Many cases of hemorrhoids are caused by lesions in the lumbar and sacral regions, and especially dislocations of the coccyx (usually anterior) and the innominata. Correcting these lesions will oftentimes cure the hemorrhoidal disorder. Simple dilatation of the rectum once a week, in addition to other treatment, is of great aid in curing hemorrhoids, not a few of the cases being cured by dilatation alone. It relaxes the tissues about the tumefied vessels. Treatment is rarely necessary above the second lumbar, (unless there is more or less of a constitutional disorder) as the superior hemorrhoidal blood vessel of the inferior mesenteric is given off about opposite the second lumbar.

In cases where the abdominal walls have become relaxed, a treatment should be given to strengthen the abdominal muscles and viscera. Particular attention should be given the liver. Treatment should be given over the abdominal muscles directly, and also to the spinal nerves of the same region. The diet should be strictly regulated and the bowels kept loose, and stimulants, indigestible food, full meals and too much meat should be avoided. Injection of cold water before stools is a good prophylactic, and applications of cold water to the protruding pile will be of some help in relieving the congestion. A squatting position during defecation will relieve considerable strain.

=Hemorrhoids= in the =acute state=, within twelve or twenty-four hours from the engorgement, yield quickly to treatment. The local technique is to relax the tissues about the tumor, especially above and along the line of the vein, then with pressure at its base carefully force out the engorged blood. Follow this up by another treatment the next day and continue until normal. The vein wall, not being permanently stretched, will contract and if the irritating cause is found, there is little danger of return. Remember, in a case like this, the danger of embolism and be sure a clot has not formed. Cases of hemorrhage at stool, during or immediately following evacuation, when not from a bleeding pile, may be of considerable quantity and the source difficult to locate. It may be due to ulcerations or easily ruptured capillaries of the mucosa, but the cause will in many cases be found in the innominata and a reduction of the lesion give relief.

=Rectal conditions=, associated with piles, and =requiring surgery= after treatment has failed, are: =hemorrhoids=, which are of such long standing as to become organized tissue, (these will keep up continual irritation and cannot be absorbed); =saccules= or pocket, formed by folds of mucous membrane catching and holding particles of feces, gradually enlarging and ending with considerable reflex symptoms; =fistulae=, complete or incomplete, may frequently be healed by adjusting coccygeal or innominate lesions, but are apt to recur from the tract not being clean in the center or bottom; =abscesses= in or about the anus or rectum are usually traced to coccygeal, innominate, or local interference to circulation; =fissure=, complete dilatation under anesthesia to insure physiological rest of parts, is probably the best treatment. It is suggested that a fissure may be healed by making surgically clean, touching with iodine and coating with collodium. =Papillae= are small, hard black-capped papules in the lower rectum, each one involving a nerve terminal and causing much distress. All these conditions give rise to much discomfort and with surgical assistance can be cured without much trouble. It is not necessary to make them a major operation and do uncalled-for things. The less surgery about the rectal sphincter the better.

=Care= of the =anus= and =rectum= after operation or successful treatment is a factor in preventing return. First, there should be soluble, non-irritating stools, which do not tend to bring about prolapse from straining. Diet and regularity contribute to this. Second, absolute cleanliness. This can only be obtained by following the stool with an enema of four or five ounces of cool water and immediately passing it. It will bring forth a considerable quantity of feces which would otherwise have been retained for another twenty-four hours. This procedure following, as it does, the stool does not in any way interfere with the normal function or create a habit. The anus should then be thoroughly washed in cool water and as thoroughly dried. Dusting with borated talcum powder, starch, etc., will prevent chafing.

GENITO-URINARY

THE PROSTATE GLAND

This gland is subject to several painful and annoying diseases, controlling, as it does, the flow of urine and exerting such a profound influence over the sexual functions. The nerves to the prostate pass between the gland and the levator ani muscle, and the secretory branches are from the sacral nerves, while Quain gives the sensory as from the tenth, eleventh (twelfth) dorsal, first, second and third sacral and fifth lumbar. Lesions affecting the prostate are occasionally found at the tenth and eleventh dorsal and

fifth lumbar, while the innominate lesions are common causes of trouble. These should be corrected, if present, and local treatment given to the gland. “Massage of the prostate,” says Lydston,[47] “properly performed, is one of the most valuable advances in genito-urinary therapeutics that has been developed in many years.” Osteopathic technique is to place the patient on the side, knees flexed, and standing in front insert the index finger. Care must be used not to bruise the gland and it must be touched lightly when sensitive. Relax tissue about the gland, and, then, from the median line with an outward movement, massage the surface of each lobe. This influences the blood and nerve supply, while the pressure will tend to relieve congestion. Length of treatment, as well as frequency, depends entirely upon conditions. Do not make the mistake of treating the perineum instead of the gland and do not gouge it with the finger. Remember it is sensitive tissue.

=Hypertrophy= is most commonly met with in practice, as twenty per cent of men past middle life are said to be afflicted. It is probably not a sequence of old age, but due to chronic, congestive and inflammatory conditions. Anything which would produce these conditions—spinal lesions, excessive venery, masturbation, or other more innocent causes—would in time bring about enlargement. As the length of catheter life is estimated at six years it is of great importance that the condition be early recognized, for in advanced stages surgery is the last resort. In early stages the prognosis is good, either for a cure or to stop further enlargement, while many enlarged ones at the catheter stage have been greatly benefited or cured. Treatment of the gland once per week is usually enough, but in older cases can be given semi-weekly. Look well to nerve and blood supply.

=Acute Prostatitis= is a serious and painful inflammation, causing urinary retention usually. It results from trauma, horseback riding, over exertion, gonorrhea and its maltreatment, etc. Lower dorsal and lumbar lesions are frequent. This condition must be closely watched. Inhibition of the sacral nerves will help control pain and stop any spasm of the sphincter. Cold applications to the gland externally at the perineum will aid in reducing inflammation. Local treatment should at first be given to the adjacent tissues as the gland will be very sensitive. Later direct massage will be of great benefit.

=Chronic Prostatitis= may follow an acute attack or it may originate as a chronic or subacute affection. Frequent micturition and dull pain, referred to the perineum and rectum, with the local examination, make diagnosis sure. The spinal lesions should be corrected and the gland massaged. This will induce absorption, by squeezing out the inflammatory products and do much toward preventing future hypertrophy. “Massage is done by the finger. The patient is placed in the knee-elbow position and massage employed for four minutes daily. The value of massage in chronic prostatitis is very great, but should be employed with much caution and never in cases of suppuration.”[48]

=Prostatorrhea= is often taken for spermatorrhea and any irritation of anterior sacral nerves would cause undue activity to the secretory nerves to the gland. This is easily determined.

=The Seminal Vesicles= can be reached just above the prostate, and if inflamed and tender or if engorged by inspissated seminal fluid, local treatment will be of benefit. Frequent massage, daily in some cases, to the gland and treatment to the sympathetic nerves above the trigone of the bladder, to the nerve fibres passing along the spermatic cord, and to the arteries directly, will be of the greatest aid in impotency.

In =Chronic Gonorrhea=, where the gonococcus has found lodgement in and about the gland, it can be more readily dislodged by massage than by any other form of treatment.

=Retention of urine= from nervous excitement or other minor causes, can often be overcome by local massage of the prostate.

=Spastic stricture= can usually be cured by work about the prostate and its innervation.

Varicocele

A varicose enlargement of the veins of the spermatic cord, epididymis and testicle. In varicocele the pampiniform plexus is usually enlarged, but all the veins of the cord may be involved. The swelling gets smaller under compression or in a horizontal position and enlarges again on standing erect. It is almost invariably found on the left side, and the testicle on the affected side is generally smaller and softer than its fellow.

The predisposing =causes= are a longer and tortuous spermatic vein on the left side; the absence of support of the veins from surrounding muscles; the imperfect valves; the entry of the left spermatic vein into the renal vein at a right angle, instead of at an acute angle like the right vein; the more liability of compression of the left spermatic vein by accumulation of feces in the sigmoid flexure; the lack of normal exercise of the sexual functions in young, unmarried adults. Lesions in lower dorsal and upper lumbar

affect the condition; the eleventh dorsal particularly. A lesion at the second lumbar may cause neuralgia of the testicle with engorgement of the vein.

The exciting causes are straining during stool, heavy lifting, excessive sexual indulgence or anything that would determine more blood to the testicles. Varicocele is similar to the varicose state of the hemorrhoidal veins and may have like causes.

The =diagnosis= is easily made. The feeling of the veins between the fingers like a convolution of earth worms; dull, aching, dragging sensation, and possibly prostration, weakness and dejectedness of spirits, are characteristic symptoms. “The condition is devoid of danger, except that it often begets morbid fears on the part of the patient, usually the result of suggestion.”[49]

The =treatment= consists of regulation of the bowels, removal of such predisposing and exciting causes as may be found, treatment of the vessels along the spermatic cord, and treatment to the lower dorsal and lumbar regions. In severe cases a suspensory bandage will give temporary relief. Surgical interference may be necessary in some cases in order to effect a cure.

Impotency

Results from treatment in these conditions are particularly gratifying and offer a great field of activity in this day of sensational medical advertising. This condition can well be classed under four heads, Exhaustive, Traumatic, Psychic and Organic.

=Exhaustive Impotency= is the result of functional abuse, masturbation in early life, excessive venery, coupled with intemperate use of alcohol and improper diet without sufficient sleep. It can be symptomatic in neurasthenia. There is at first irritation of the spinal centers, which causes exaggerated sexual activity, and later this is followed by complete or partial loss of function. The first step is for a radical reform in habits; regulation of the bowels, as they will likely be constipated; direction of the mind into wholesome channels, and then skillfully directed spinal treatment. Where there has been masturbation, look well for sources of irritation to the parts; a long foreskin or adherent prepuce indicates surgical aid, or there may be a lesion at the sacrals involving the nervi erigentes or, of greater importance, the pudic nerve. The innominatum can be at fault in this. The lower dorsal, ribs and upper lumbar are of importance. Kraft-Ebing says: “Conditions of absolute impotency are, however, rare, and are caused =only= by severe vertebral and nervous diseases.” Nerve irritation undoubtedly is the cause of sexual perversion (outside of heredity and malformation) so their relief is as necessary to bring about reform of habits as to effect a cure. Where the general health is affected constitutional treatment should follow. Motschutkovsky uses suspension in treating these cases with good results. The effect is to separate the vertebræ, freeing spinal nerve and blood channels. The prostate will probably be found in an irritated, sensitive condition, as well as the seminal vesicles. Treat as outlined under the prostate gland. Ligation of the dorsal vein of the penis is recommended by some authorities as tending to aid turgescence of the organ. Prognosis is so dependent on how well the patient follows directions, age, environment and general condition that it is hard to give, but as a rule is rather favorable.

=Traumatic Impotency= is a strictly osteopathic classification, for the reason that sexual weakness is often traced to lesions resulting from remote injuries. These injuries may be to the spine, ribs or sacrum. The lower spine may be impacted from a fall or the result of long continued riding on rough streets or the railway. This inhibits the nerve supply to the extent of often seriously impairing the sexual functions. If the cord is injured to any extent the results are more serious. Treatment in these cases has given uniformly good results. It will always be due to a specific lesion, so the examination must be thorough.

=Psychic Impotency= is the form most frequently met with and generally the most difficult to cure, yet it should not be if the patient’s confidence can be secured, for in many cases sexual power is but slightly impaired, but owing to the suggestions given by the medical advertisers the victim diagnoses his own case as hopeless. “It is not uncommon that virility returns with the peace of mind.”[50] Observe all the procedure given and then inspire hope where it can be honestly given, and if the patient is progressing favorably, other things being equal, advise early marriage under strict rules of conduct. If already married, conjugal relations should be most carefully investigated and the wife taken into your confidence. Her cooperation in correcting very possible errors in sexual matters, as well as sympathetic aid in easing the patient’s anxiety and chagrin, will be invaluable. Nothing but the frankest understanding between all parties is permissible and the osteopath must be in absolute control.

=Organic Impotency= is the result of a cortical injury or disease. The latter is the most common, as it follows tabes dorsalis, paralysis affecting the lumbar cord, some cases of diabetes, etc. Also, any congenital malformations or absence of all or part of the organs. Prognosis in these cases is bad, as cure is seldom possible.

In no other class of cases will honesty, tact and good judgment count for so much or the rewards be greater.

HEAT STROKE

(Heat Exhaustion: Sunstroke)

An affection produced by exposure to excessive heat. Two varieties are recognized; heat exhaustion and thermic fever.

=Heat Exhaustion.=—This is caused by prolonged exposure to high temperatures, combined with physical exertion. Fatigue, overeating, alcoholic drinking, and poor sanitation predispose. This may occur without exposure to the direct rays of the sun, the heat being artificial, or in mid-summer, in close, confined rooms the same result will be produced. There is vasomotor paralysis, the surface of the body is usually cool, the temperature may be as low as 95 degrees F., while the pulse is small and rapid.

=Sunstroke= or =Thermic Fever=.—This is usually caused by prolonged work under the direct rays of the sun in a humid, very hot and sultry atmosphere. This is caused by the action of the heat upon the heart centers producing a paralysis of those centers.

=Pathologically=, rigor mortis develops early and is marked. Putrefactive changes appear early, owing to the high temperature of the cadaver. The various organs are deeply congested, the venous engorgement is extreme in the cerebrum. There is rigid contraction of the left ventricle; while the right is dilated and filled with blood. The blood is fluid and dark. Parenchymatous changes take place in the liver and kidneys.

In heat exhaustion with lowered temperature there is a paralysis of the vasomotor center in the medulla, and the heat is dissipated more rapidly than it is produced. In thermic fever the heat regulating centers become paralyzed by the action of the excessive temperature and more heat is produced, and less dissipated than normal.

=Symptoms.=—=Heat Exhaustion.=—This may occur gradually or suddenly with a severe attack of faintness, pallor, dizziness, headache, cold perspiration and sometimes blindness as the first symptoms. Consciousness is rarely entirely lost. In severe cases there is more permanent collapse. The pulse is rapid and feeble and there is great restlessness and delirium. Under prompt treatment mild cases may recover in a few hours, while in extreme cases death may occur almost at once from heart failure.

=Thermic Fever.=—In some cases the patient is struck down, becomes quickly unconscious, and may die within an hour, or death may be almost instantaneous. In other cases there is pain in the head, oppression, dizziness, nausea, vomiting and sometimes diarrhea or frequent micturition. Soon unconsciousness sets in, the face is flushed, the eyes injected, the breathing labored and there is a temperature of from 105° to 110° F. The pulse is full and rapid, the skin hot and dry and the pupils are contracted. There is usually complete relaxation of the muscles, and in some cases there is twitching and jactitation. Epileptiform convulsions are rare. In fatal cases the coma deepens, the pulse becomes feeble, rapid and irregular, the breathing hurried and shallow and death occurs in a few hours. Favorable cases are indicated by a fall in the temperature and by the return of consciousness. In these cases recovery may be complete. In some cases the patient may never be able to stand even moderate degrees of temperature, which often produce excitement, headache and pain in the cervical region. Failure of the memory, and the loss of power to concentrate the mind are sometimes sequelæ. Meningitis, epilepsy and insanity are also sequelæ.

=Diagnosis.=—This presents little difficulty. The history and circumstances preceding the attack are very important in making the diagnosis. The diagnosis between heat exhaustion and sunstroke fever is readily made. In heat exhaustion the temperature is =lowered=, the pulse is feeble, consciousness is rarely completely lost; in sunstroke fever the temperature is extremely =high=, there is usually complete unconsciousness, and the pulse is full and rapid.

=Prognosis.=—This should be guarded, depending upon the severity of the case.

=Treatment.=—In cases of =heat exhaustion= remove the patient to a shady place and apply water to the face, chest and spine. Thoroughly treat the upper cervical region, in order to control the impaired vasomotor centers and nerves. If the temperature is

below normal a hot bath should be given. Keep the heart and lungs stimulated.

In =sunstroke=, place the patient in a recumbent position and loosen all constricted clothing, and stimulate the heart's action. The high fever is to be met promptly. Place the patient in a bath of water, to which add ice freely. The patient may also be rubbed with ice, and ice water enemata may be employed. The muscles of the neck will be found contracted, probably due to cerebral hyperemia. A thorough relaxation of these muscles will be of great aid in equalizing the vascular system. It is a good plan to thoroughly relax all the muscles along the spinal column for the same purpose. When the temperature nears normal the baths should be stopped. After the temperature has been reduced place the patient upon a cot with ice to the head. The cervical treatment should be repeated as often as necessary. The diet of the patient should be liquid for a few days. Plenty of water and stimulation of the kidneys and bowels will be found beneficial. The sequelæ are to be treated according to the condition. Much can be done for the sequelæ of heat exhaustion and sunstroke. Lesions will be found corresponding to the regions involved. Deep contracted muscles are common.

DEPARTMENT OF OPHTHALMOLOGY

By C. C. REID

It is the desire to make this discussion on the eye the most useful possible to the whole profession. Let it be plainly understood that there is no effort to cover every phase of eye pathology but to elaborate eye diseases and therapeutics strictly from the standpoint of osteopathy. There are many very elaborate and extensive text books and even encyclopediæ written on the eye by the medical profession. The world of ophthalmic literature is extensive and profound. Just so are the elaborations on the general field of medicine. Such things as hereditary influences, congenital deformities, amblyopias, albinism, coloboma and the field of ophthalmic surgery does not concern us at the present time in an osteopathic text book. This department is dedicated to a scientific development of ophthalmic therapeutics along osteopathic lines of thought. Some things in the therapeutics of the eye concern all schools alike. For instance, proper cleanliness and antiseptic precautions in regard to the eye, dietetics, hygiene and the care of the general health. The same anatomy and many of the same methods of examination and diagnosis obtain in all schools. It is the intention to go into the opthhalmic therapeutic field in these discussions where osteopathy has a different outlook with a definite distinct reform to offer in the viewpoint of the anatomy, methods of diagnosis and the system of treatment.

How to Examine an Eye

It has been said that one should be a good general man in order to be a competent specialist. This is especially true in regard to ophthalmic therapeutics. Many systemic diseases have eye symptoms and pathology. The same blood and lymph that nourishes and bathes different parts of the body, also circulates in the structures of the eye. In the examination of the eye, heredity, occupation and environment are to be taken into consideration. Osteopathic lesions may exist from falls, strains, twists, blows, colds and exposure and impair the integrity of the metabolic processes of the eye through the nerve connections and blood supply and lay the foundation for a great variety of eye diseases. With these lesions existing about the neck and upper dorsal, it is only required to have some insignificant local irritant to start symptoms and cause pathology apparently out of all proportion to the etiology. It is important then that one understand the nerve centers and reflexes and the osteopathic logic underlying these conditions or else he must frequently work without a satisfactory explanation of the etiology and consequently be more or less unscientific in his treatment.

The eye examination should consist of the case history, the family history, inspection, osteopathic examination, especially from the fourth dorsal vertebra to the occiput and especial examination of the eye by inspection and other methods.

=1. The Case History.=—Thoroughness of the doctor, or the lack of it, will be readily displayed at this point. Every little thing, as far as possible, that has a bearing on the case should be observed and uncovered in the case history. The physician should want to know every fact that helps him to better understand his case. Patience in hearing the history will often be of great assistance. It gives light on the physical and mental condition of the patient. Much can be gained by being careful and attentive. Notice carefully what he emphasizes and what he thinks is the most important. Inquire in regard to headaches, nervous symptoms, previous eye trouble and past illnesses. Get a venereal history if present, as many eye diseases are complicated or caused by syphilis or gonorrhea.

=2. The Family History.=—Inquire as to blindness in the family and about the age it occurred, if any. Get a venereal history if possible.

=3. Inspection.=—Much inspection can go on while the history is being taken. Observe the countenance, whether there is strabismus or frowning due to eye strain, photophobia as suggested by the effort to avoid the light; note symmetry. Look closely at the lashes, lids, conjunctiva, cornea and iris. Note any scales or crusts on the lids at the root of the lashes. Turn the lids for further inspection. Note the size and relation of the eyes. Exophthalmos may be due to an enlarged globe in high myopia, to Graves' disease, orbital tumor and paralysis of the extrinsic muscles, or staphyloma. In blepharospasm there may be a corneal ulcer or a rupture of the eyeball. An exact examination must be made at the first visit in order for a diagnosis to institute the best treatment possible. Study the conjunctival sac for congestions, hypertrophy, swelling, tumors, foreign bodies, trachoma bodies and secretions. In all forms of conjunctivitis the congestion is most marked in the fornix and decreases toward the sclerocorneal junction. In iritis and cyclitis there is a circumcorneal injection, a pink or red color radiating from the cornea. Note any corneal pathology in the way of ulcers or abrasions and foreign bodies. Compare the tension of the eyes.

=4. The Osteopathic Examination of the Eye.=—This heading is put here in order to show what osteopathy has to offer that is distinct as belonging to our system and not practiced by any other school. Osteopathic research so far has shown that osteopathic science has much to offer on etiology and diagnosis and treatment in eye diseases. The case history, family history and inspection should require but a few minutes but they are essential to a proper examination and may aid us in what to expect osteopathically. Weak nerves will cause asthenopia. A broken arch, an innominate lesion or a slipped axis may cause weak nerves. The osteopathic eye examination then should consider the whole mechanism of the body. In case glasses are being worn for asthenopia they may readily be made unnecessary by osteopathic treatment in the correction of the lesions and building up the system. Some time ago some parents sent their daughter to me to have her eyes fitted for glasses. They stated that she had been to different doctors and opticians and no one had ever given satisfaction. They said she was all right every other way if her eyes were properly fitted with glasses. They did not want her examined or treated otherwise because she would be well every other way with correct glasses. Her vision was right eye 5-20, left eye 5-15 or about one fourth vision in each eye. A plus .87 diopter sphere combined with a plus 3 diopter cylinder in axis 90 gave her perfectly normal 5-5 vision in each eye. This gave her perfect satisfaction until she started to school in September, a couple of months later. Before the end of the first month she was having trouble with her eyes and was again sent to me by her parents. Her vision was reduced to 6-15 in each eye with her glasses on. She wondered and no doubt the parents did, if it was not another case of a misfit in glasses similar to all her previous experiences. This time I insisted upon a thorough physical examination against all protest. The following lesions were discovered: the left innominate was up and back or tilted posteriorly, first lumbar anterior and to the right, sixth and first dorsals to the right. The case was not refracted again. I took particular care the first time and I was quite sure the refractive error was corrected. It was all explained to the parents and regular osteopathic treatment was begun. In less than a month practically every lesion was corrected, her vision returned to normal and she also was cured of an annoying backache with which she had been bothered for years. Her nerves were depleted a great deal. She got benefit in ways that she had not dreamed of. This approach to the eye is not considered by physicians in general, even the oculists. I have had about ten special courses in medical colleges and hospitals on the eye, ear, nose and throat, and I have never heard anything mentioned that would indicate any ideas of the logic involved in this case. Surely osteopathy has much to offer in eye troubles that is new and unique. The osteopathic examination of the eye then should begin with the feet, going then to the innominates, lumbar, dorsal, ribs and cervical regions. Oculists are too prone to rely upon crutches (glasses) in the treatment of asthenopia.

It is easy for the osteopath to conceive how lesions of the upper dorsal and cervical regions may occur and disturb the nerve and blood supply to the eye. This is why asthenopia appears so frequently with ordinary use of the eyes, even without abuse or refractive errors.

The Lumbar Region

The lumbar region should be carefully examined, especially for any curvature which might cause a disturbance of the equilibrium above. Compensatory curves or individual lesions would be the result with a consequent interference with the integrity of the nervous reflexes to the eye.

The Dorsal Region

The same may be said of the dorsal region as of the lumbar in regard to curvatures. There is one individual lesion in this region that very frequently exists with eye troubles, i. e., the 2nd dorsal vertebra lateral. Any of the upper four dorsals in lesion may be a causative factor in predisposing to disease of the eye but it has been my observation that the 2nd is involved most often. In severe headaches due to eye strain from refractive error, a good diagnostic symptom is tenderness and contraction at the 2nd dorsal even when there is no subluxation.

The Cervical Region

This region should have particular care in search for individual lesions. It is quite easy to pass over some small cervical lesion that may be causing serious disturbance, especially if the neck happens to be fleshy. I have corrected cervical lesions and stopped twitching of the eyelids (orbicularis palpebrarum) and other muscles about the face.

The first case I ever saw was twenty-two years ago when I was a junior at Kirksville. Dr. F. P. Millard, now of Toronto, was a room mate of mine. He was constantly annoyed by a twitching of an eyelid. I did not find any lesion for it. We went one day to see Dr. Still at his home and told him of our difficulty. He said without examination that the 3rd cervical was in lesion. There was a senior student present whom the “Old Doctor” directed how to use the proper technique. There was a sharp pop, the vertebra evidently went into right relation, the twitching stopped. I understand the patient has had very little trouble since.

Injuries, exposure and strains to the spine may have antedated an innominate lesion and caused weak joints, muscular and ligamentous tension, local inflammations and partial immobilization of joints. All this would have its modifying effects upon the manifestation of secondary lesions from the innominate abnormality. This makes the study of the bony relations very complex and the effect upon the numerous blood vessels, nerves and other soft tissues still more complicated.

The Ciliospinal Center

Following osteopathic examination and giving proper importance to lesions below the fourth dorsal vertebra, we must remember a special significance to be attached to lesions of the =upper dorsal= in relation to the eye.

Almost any author on nervous diseases or diagnosis will discuss this center. Many of us have it not sufficiently impressed, hence I repeat some known relations. The =ciliospinal= center consists of a nuclear group of cells in the lateral horn of the last cervical and two upper dorsal segments of the spinal cord. From this nucleus fibers pass to the anterior division of the eighth cervical and first and second dorsal nerves and become the white rami communicantes which are efferent in their function. These fibers pass to the =inferior cervical sympathetic ganglion=, thence upward with the sympathetic trunk through the =middle= and =superior cervical sympathetic ganglia=, along the carotid plexus to the vessels of the face and eye, to the glands of that region, to the unstriped muscular fibers of the levator palpebræ superioris and to the =dilator pupillae muscle=.

Any strong feeling or emotion (which of course is perceived and interpreted by the brain cortex) will cause a dilatation of the pupil of the eye. The cervical sympathetic being cut, dilatation does not take place. The rami of the cervical, first and second dorsal cut, the phenomenon stops. It is evident the ciliospinal center is under the influence of a center or centers in the brain. Bing says “There is even an idiomotor mydriasis, which may be brought about by a very vivid mental conception of darkness.”

It has been noted that paralyzing lesions of the cervical sympathetic, of the last cervical and two upper dorsal segments of the cord, and of the anterior roots and rami communicantes of the same, will result in myosis.

The efferent rami are also vasomotor, secretory and trophic. It must necessarily follow that congestive and inflammatory conditions, secretory perversion of the lachrymal, Meibomian, Zeissian and perspiratory glands, and disturbance of the normal nutrition of any of the orbital tissues may result from lesions of the lower cervical and upper dorsal vertebræ.

Osteopathically we know that such a lesion may not be sufficient to be paralytic in its effect, but stimulatory. In this case we may note a pupil habitually too wide and more or less photophobia from a superabundance of light. The unstriped muscle fibers in the levator palpebræ superioris may be unduly contracted making an appearance of a slightly bulging eyeball when it is only a wide open eye.

One who has eye strain from a refractive error, overuse of the eyes, or unbalanced muscles will as a rule have tenderness at some spot in the region of the =ciliospinal= center. A mechanical lesion at that part of the spine may or may not exist in such conditions, but I believe the soreness is there every time. This is one of the diagnostic points in differentiating =headache= of eye strain from

other conditions.

White rami are only in the dorsal region and to the second lumbar and from the second, third and fourth sacral. It has been noted that lesions of the cervical vertebræ do not have as profound an effect upon the eyes as do lesions of the first three dorsal vertebræ. The plausible explanation of that is that the cervical vertebræ have no white rami from their corresponding nerves in the bulbo-spino-sympathetic-ciliary arc as have the upper dorsal.

From all the foregoing statements one can readily contemplate the intricate complexity of our osteopathic problems in relation to the eye. Combine this logic of the lesions outlined and the ramifications of the structures with their normal and perverted functions and combine it with contributing causes, such as infection, exposure, irritants, etc., and amidst the great diversity we reduce much miscellaneous, unclassified material to a degree of simplicity. Many otherwise unexplainable conditions become reasonably clear.

Dr. Louisa Burns under “The Experimental Demonstration of Osteopathic Centers” has this to say:

“Somatic Reflexes”

“In the first series of experiments, the electrodes were placed upon the nasal mucous membrane of animals under anesthesia. The muscles near the third thoracic vertebra were at once strongly contracted....

“The electrodes were then placed upon the conjunctivæ. The muscles near the second vertebra were then contracted. There were also slight and inconstant contractions of the cervical muscles....

“The electrodes were placed upon the eye ball. The muscular contractions were sometimes noted near the second thoracic vertebra, but the reaction was not constant. The cervical muscles were scarcely contracted at all.

“The electrodes were placed upon the outer surface of the eye lids. The facial muscles were contracted very quickly and forcibly, but no contraction of the muscles of the upper dorsal region were noted....

“The =superior cervical ganglion= was exposed to view, and the electrodes placed upon it. The pupils became greatly dilated, the conjunctivæ became lighter in color, and the mucous membranes of the nose and throat were also lightened....

“The =Gasserian ganglion= was exposed to view. The ganglion was stimulated directly. The upper thoracic muscles were very strongly contracted, and the blood vessels in the area of the distribution of the fifth nerve were immediately and strongly contracted. Some of the sympathetic fibers are carried by way of the fifth nerve. In order to exclude the effect of the direct stimulation of these fibers, the fifth nerve was cut, and the central end was stimulated by the electrodes. The muscles of the upper thoracic region were contracted, as before. The vessels in the area of distribution of the fifth nerve were contracted after latent period of a minute or so....

“The stimulation of the central end of the cut fifth nerve caused strong muscular contractions in the upper thoracic region, and also constriction of the vessels in the area of distribution of the fifth. Direct stimulation of the superior cervical ganglion produced effects identical with those produced before the mutilation.

“The spinal cord was cut above and below the superior cervical ganglion. This cut was made from behind, and the sympathetic chain was uninjured. The effects noted after both operations were the same, and can be described as one.

“The stimulation of any cranial structure failed to cause reflex contraction of the muscles in the upper dorsal or the cervical region.

“Stimulation of the cranial structures did not produce any vascular changes except those which might be referred to the direct effects of the electricity upon the vessel walls.

“Direct stimulation of the =superior cervical ganglion= produced the effects noted before mutilation.

“Therefore the cervical portion of the spinal cord is an essential element of the reflex arc by way of which sensory impulses from the cranial structures are able to affect the condition of the upper dorsal muscles, and also in the path by which these impulses are able to affect the size of the blood vessels of the cranial structures themselves....

“Mechanical stimulation of the tissues near the second thoracic spine was followed by a contraction of the blood vessels of the cranial mucous membranes and the conjunctivæ, by a dilatation of the pupils, and an increased secretion of saliva. These effects were practically invariable....

“The superior cervical ganglion was subjected to mechanical stimulation by the manipulation of the tissues over it. In animals, this maneuver was followed by dilatation of the pupils and by a contraction of the cranial vessels, which was soon followed, if the stimulation continued, by a dilatation which was rather persistent.

“After the =extirpation= of the =Gasserian ganglion= without the injury of the sympathetic nerves, the mechanical stimulation of the tissues near the second and third thoracic vertebræ caused the same vaso-constriction and =pupilo-dilation= as was observed in the animal before mutilation.

“After the destruction of the cervical portion of the sympathetic chain, and after the extirpation of the Gasserian ganglion in most animals, the mechanical stimulation of the tissues in the upper dorsal region did not produce any perceptible effects....

“Mechanical stimulation of the tissues near the second and third thoracic spines caused dilatation of the pupils and contraction of the vessels of the cranial mucous membranes.

“Inhibition, or the maintenance of an artificial lesion, caused dilatation of the vessels of the nasal mucous membranes and of the conjunctivæ. The eye ball was also somewhat congested. The pupils were dilated in this case also.”

The Nose and Throat in Eye Trouble

An examination of the eye would not be complete without a careful inspection of the =nose and throat=. The same nerve and blood supply that go to the eye is tied up so definitely with the nose and throat that when there are lesions of the nose and throat the eye is often affected secondarily. Just recently a case of =dacryocystitis= came into my office. After I had carefully examined her eye, spine, nose and throat, she informed me that she had been to three eye specialists before and not one of them had ever looked at her nose and throat, not to mention the spine. She had cervical and dorsal lesions, and =diseased tonsils=. The =inferior turbinate= on the side of the dacryocystitis was curled out so that it lay against the external wall of the nose almost if not altogether blocking the entrance of the =lacrymal duct= to the inferior meatus. This was evidently the predisposing cause of her dacryocystitis.

In =neuralgia= of the eye, =blepharitis=, =obscure pain=, =conjunctivitis= and often deeper troubles you will find a bad condition of the =nasopharynx=, such as adenoids, vegetations, pus pockets, adhesions in the fossa of Rosenmuller, contraction of the soft palate, disturbed relations of the septum and turbinates, sinus trouble, poor drainage, exostoses and polyps. In eye disease all these things should be discovered if they are present, in order to get best results and in order to make a careful diagnosis.

Examination of the Eye by Special Methods

The first thing after the family history, personal history, inspection of the eye and the osteopathic examination, is to find out how well the patient can see. To test the acuteness of vision certain test letters are used. Snellen’s Test Letters are good. The normal eye can read 3-8 inch letters at twenty feet. The test letters on the cards usually range in size to be read at 10, 15, 20, 30, 40, 50, 70, 100 and 200 feet. The most desirable distance is 20 feet. If at the distance of twenty feet he reads the 3-8 inch letters his acuteness of vision would be marked 20-20 or normal. Always use the distance between patient and chart as the numerator of the fraction and the number above the letters which he reads as the denominator. If he is twenty feet away, the numerator remains twenty and the denominator changes according to the line of letters seen on the test cards thus: 20-15, 20-30, 20-70, or 20-200 may express the vision. If the patient could not see the 200 feet letters at 20 feet he must be brought nearer, say 10 feet, for him to see the large letters; his vision would be 10-200. These fractions representing the acuteness of vision may be expressed in meters. Some charts have letters numbered that way.

If the vision is good enough for small objects to be clear, the near point should be taken. This would show the amount of accommodation of the eye. This is expressed in diopters.

A =diopter= is the unit of measurement of the =refractive= power of lenses. =Lenses= are numbered by their refractive power in diopters. A lens that has a curvature that will refract parallel rays of light and bring them to a focus at one meter distance is said to be a one diopter lens. This unit of measurement for the refractive power of lenses was proposed by Nagel in 1866. It soon became quite generally used.

The focal distance of a lens decreases as the strength of a lens increases. One diopter lens (written 1 D) has a focus of one meter (1 M) or 100 cm distance. A 2 D lens has a focal distance of ½ M or 50 cm. A 4 D lens has 25 cm focal distance and a ½ D lens has 100 cm ÷ ½ = 200 cm distance or 2 M. Trial cases have in them lenses varying in strength from .12 D or .25 D to 20 D of the

spheric form. We will not discuss the trial case here.

Accommodation in the Eye

=Accommodation= in the eye is the ability of the eye to vary its focal point. When the normal eye (emmetropic) is at rest its focal point is at infinity so far as parallel rays are concerned. This is called the far-point or the “=punctum remotum=” (P. R.).

When the eye looks at letters twenty feet away it scarcely accommodates at all to get a focus, or so little that it may be disregarded in ordinary practice. Now if one brings fine print close to the eye he will find a point so close that it becomes indistinct. This point is the near-point of focus or the =“punctum proximum”= (P. P.). The range of accommodation is the difference between the refractive power of the eye when it is at rest and when the accommodation is exerted to the utmost, the difference between the P. R. and the P. P.

If one must accommodate one diopter to get a focus at one meter or forty inches distance, at thirteen inches or reading distance one must accommodate at least 3 D in order to see the letters clearly. If 3 D were the total of his accommodation he could not read at that distance but a few minutes; because the accommodation could not be held at its maximum for long at a time. Eye strain with its train of symptoms would result. Hence it is quite important to find the near-point or punctum proximum in order to judge in regard to eye strain in an emmetropic eye. If there is a refractive error, allowance for it must be made accordingly.

As a person gets older the accommodation in the eye becomes less and less until at 45 years of age he can only use 4 to 5 D of accommodation. This is so close to the amount required for reading that he has some eye strain. He begins to hold his paper farther away from him so he requires less accommodation. This condition we call “old sight” or =presbyopia.= An emmetropic eye at forty-five to fifty years of age requires a plus glass to make up for some accommodation in reading.

Frequently there are latent disturbances of equilibrium of the extrinsic muscles of the eye. This is =heterophoria.= If it is a latent convergence it is =esophoria=; if a latent divergence it is =exophoria=. The latter is more frequent. Hyper- and hypophoria are used for upward or downward tendencies. Normal muscular balance is =orthophoria=.

Cause the patient to fix on an object about thirteen inches away with both eyes; push a sheet of paper in front of one eye and watch behind the paper, the eye thus covered. If heterophoria exists the eye will move slightly from its point of fixation since it no longer sees the object. In orthophoria it will remain fixed as long as the other eye sees the object; the innervation to the different muscles is properly distributed.

A Maddox rod found in any complete trial case may be placed before one eye. Have the patient fix on a candle flame, say twenty feet away. The flame appears drawn out into a luminous line. This line can not be fused with the candle flame as the other eye sees it if there is heterophoria. The amount and kind of disturbance is somewhat indicated by the distance and direction of the luminous line and the flame. The exact amount can be measured by the use of a prism that will cause them to fuse.

Next the patient should be taken to the dark room and a careful inspection of the anterior segment of the eye should be made with oblique illumination. First use the unaided eye, then use a lens that magnifies. The 20 D plus lens from your trial case will suffice for the magnification. Note the transparency or lack of it in the cornea and crystalline lens; the depth of the anterior chamber and the appearance of the pupil and iris. Now we are ready for the ophthalmoscopic examination.

=The Ophthalmoscope.=—This is an instrument that commands great respect. Any one who is interested in eye troubles must have and use the ophthalmoscope if he expects to be efficient in diagnosis, upon which, of course, intelligent treatment must forever depend. One must try and try again in order to become proficient in the use of the ophthalmoscope.

A Schematic Eye is of great assistance to a beginner who does not have clinics or patients on whom to practice. Such an eye with full directions can be obtained at almost any optical goods store. It will make the study of ophthalmoscopy easy and interesting. The pupil can be regulated to any size and the eye can be made short (hyperopic), long (myopic) or normal (emmetropic) for study.

The efficient use of the ophthalmoscope makes the diagnosis of internal diseases of the eye as easy as the diagnosis of external diseases of the eye. Only some rare conditions will puzzle, and that is true of any part of the anatomy.

The ophthalmoscope is a simple instrument; its chief function is to illuminate the interior of the eye. The value of ophthalmoscopic findings depends on their correct interpretation by the examiner.

The ophthalmoscope has a mirror to reflect the light into the eye. It has two discs on which are mounted convex (plus) and concave (minus) lenses. The larger disc has seven plus and eight minus lenses. To these may be added the lenses in the smaller disc making many combinations.

A drop of a 2% solution of cocaine or homatropine may be used as a mydriatic where one can not otherwise see clearly the fundus. If no mydriatic is used a somewhat weak illumination should be employed in order not to arouse the accommodation to much activity and make the pupil small. If there is any opacity in the media a strong illumination should be used. The room should be dark; the darker the better.

There are two methods of using the ophthalmoscope. The =indirect= and the =direct= methods. One is more useful at one time and the other at another time. By the indirect method we view the whole field of the fundus more readily but less in detail. With the ophthalmoscope before his eye the examiner's face is twelve to fifteen inches from that of the patient. When the "=red reflex=" of the eye is seen a plus 13 or 16 D lens is interposed near the patient's eye. This magnifies the field. The image is inverted. As a rule it is best seen with a +4 D lens in the aperture of the ophthalmoscope.

This method is especially more satisfactory in high degrees of myopia and astigmatism. The =optic disc= is the objective point. One may see a retinal vessel first; this should be followed to its emergence from the disc. From this point view all parts of the fundus by having the patient look in different directions. This is better by the indirect method than for the examiner to vary his position.

The direct method of ophthalmoscopy is better for detail work and in all cases except high degrees of myopia and astigmatism. It is also better in determining errors of refraction. The patient looks straight across the room. For a beginner it may be essential to dilate the pupil, hence the schematic eye as suggested.

If the examiner has a refractive error, he should wear his own glasses or correct by throwing in front of his eye proper lenses in the ophthalmoscope. Face the patient and sit on the side of the eye to be examined. Use left eye to examine the patient's left eye and right eye for the patient's right. Examiner and patient keep both eyes open. The examiner may not be able to suppress the image of his other eye and may have to close it part of the time. Catch the "red reflex" some 15 to 18 inches away and move close to the patient's eye. The "red reflex" color varies with the error of refraction, the transparency of the media, the degree of pigmentation and the size of the pupil. A blood clot will make it redder, some exudates will make it gray or yellow.

The examiner may approach as close as half an inch from the eye to be examined. Find the optic disc and examine all points of the fundus from it. Rotate in glasses to correct the patient's refractive error if he has any. The strongest plus glass with which the fine retinal vessels can be clearly seen will represent the =hyperopia= of the eye. This is true only if the examiner's accommodation is at rest. The weakest minus glass with which the fine retinal vessels can be clearly seen represents the =myopia=.

=A Normal Fundus.=—The color of the fundus is due to the blood vessels of the retina and choroid and the connective tissue of the choroid and sclera. Variation is due to the pigment. In the albino it is light pink. In the negro it is dark reddish. There are all gradations between the two.

The =optic disc= is the end of the optic nerve as it comes into the eye; it is circular in shape, pink in color, and sharply defined. It is about 1-16th of an inch in diameter; about 15° to the nasal side of the pole of the eye and slightly above the horizontal. There may be a dark =choroidal ring= around the disc or part way around. There may also be a white ring caused by the sclera. As a rule there is a depression in the center of the disc out of which the retinal vessels emerge and spread out over the fundus.

The =fovea centralis= or point of clearest vision is located two and a half disc diameters to the temporal side of the disc. Around this is a circular area of light yellow, the =macula lutea=.

The subject of ophthalmoscopy has been touched upon somewhat in detail because of its great importance to the general practitioner. Every osteopathic physician should know the ophthalmoscope well enough to recognize the ordinary lesions inside the eye. When we take up pathological conditions of the eye we will have occasion frequently to refer to the ophthalmoscopic appearance. Without the use of this instrument all of our clinical field research on internal diseases of the eye is valueless. Many have told me they have cured cataract with osteopathic treatment, some say they have cured specific neuroretinitis with no sequelæ, others testify to opacities and blindness from various causes. Invariably we ask if they used the ophthalmoscope in their diagnosis and with it watched the progress of the case. Almost invariably the answer is "no, it looked like it," "the symptoms indicated it," or "Dr. so and so, an oculist diagnosed it as such." Fellow Osteopaths! we can not base our claims on this kind of data. With a little study and practice the ophthalmoscope can be mastered. Not till then can we get reliable statistics on internal diseases

of the eye in our case reports. Osteopathy has much to reveal to us in this field and for the sake of the science and our patients we appeal to every one to do the work here set forth.

Diseases of the Eye

OSTEOPATHIC MANIPULATION FOR EYE DISEASES

A general correction of lesions should be made in order to give perfect alignment and equilibrium. Lesions that affect the nerve and blood supply will be found from the fourth thoracic to the occiput; more often at the occiput, atlas and axis in the cervical region and the second and third thoracic in the dorsal region including the ribs.

Correction of these lesions must have specific attention in every case of eye disease that shows any tendency to chronicity or in repeated eye disease and exacerbations.

A thorough upper spinal treatment to insure good mobility of all joints and establish freedom of fluids and forces is recommended.

The =nose=, _throat_ and =sinuses= should be examined for pathology. If the tonsils and pharynx are not normal the cotted index finger should be introduced into the mouth until the anterior pillar of the fauces is reached. A mouth gag may or may not be used. Massage the tonsil through the anterior pillar then move to the top and press down on the tonsil with a pumping motion. Repeat this from below the tonsil and posteriorly. Slip the finger under the soft palate and stretch it thoroughly. Clean out any adhesions and vegetations in the vault of the nasopharynx and fossa of Rosenmuller. Stretch the pillars of the fauces by pressing down on each side at the root of the tongue.

If the sinuses are diseased they should be drained. If the nose is diseased and has abundance of secretion, first use irrigation for cleanliness.

Manipulation in the nose will be of great benefit in some eye diseases as pathology there frequently has an important bearing on diseases of the eye. The nose is often too narrow and contracted. The first inch of the nose is muscular and cartilaginous; it is of even more importance to dilate the nose in contractured conditions than it is the sphincters at the lower end of the rectum. The great benefit derived from rectal dilatation has been recognized for years.

In dilating the contracted nose a wide blade nasal speculum may be used. The cotted and oiled little finger may be used where it is properly adapted in size. The dilating can be done with practically no pain and no damage to membranes or other tissues. It should not be extended beyond the cartilaginous and muscular part. Manipulation of the turbinates and tissue further back may be done if needed, by the use of instruments. The Edwards turbinate adjuster instrument (Aloe Co., St. Louis) or the Ruddy Nasal Third Finger (Sharp and Smith, Chicago) are the best instruments so far devised for this operation.

A thorough stretching of the =eyelids=, manipulation of the =eye ball= and the points of the fifth nerve are indicated in many diseases.

The lids may be stretched by pulling them from side to side. The cotted forefinger well oiled (sterile vaseline) may be slipped into the conjunctival sac back of either lid and with the thumb on the outside the lid may be massaged or stretched in any direction. The points of the fifth nerve may readily be influenced at their respective exits about the orbit. The eye ball and deeper contents of the orbit can be profoundly treated by pressing the finger into the orbit above, below and at the sides of the bulb and pushing it in all directions as far as possible. The Ruddy eye finger instrument was devised for this deep manipulation of the orbital and bulbar structures. It is of high value. One finger may be laid on the closed eye and with a tapping motion with the other hand a vibration or oscillation of the orbital structures may be had. This is a useful treatment.

The wise selection and skillful use of these various methods of treatment for the eye will solve most of our difficulties.

This short survey of osteopathic methods will aid us in the more specific discussions to follow.

Neuralgia

A considerable number of people seem to be subject to attacks of pain in one or both eyes. These attacks of pain come at varying intervals; in some cases several times a day, in others as far apart as one or two weeks. The pain will suddenly start almost without warning and with very little provocation, and last from one to twenty-four hours. It is very severe and the patient frequently thinks

something terrible is wrong. Something terrible is wrong so far as his comfort is concerned. But in these cases to which I am referring there is no organic trouble with the eye. The patient does not need glasses. There is no sign of inflammation. Vision is not disturbed. Local examination of the eye with the ophthalmoscope reveals that the fundus of the eye is normal. There is no symptom connected with the eye except pain, occasionally accompanied by a slight redness. I have had several cases in my own practice and my attention has been directed to cases of other physicians.

These cases differ from _tic douloureux_ in that there is no muscular spasm. In fact, motor nerves do not seem to be involved. The involvement seems to be largely in the =fifth cranial nerve=, usually the supraorbital, or other smaller branches of the ophthalmic division of the fifth cranial. Sometimes we note slight dilatation of the pupil with more or less congestion. This would indicate an involvement of the sympathetic branch to the eye.

The lesions discovered in these cases have been a subluxation of the occiput upon the atlas or an upper cervical lesion and frequently some involvement at the second dorsal. There has been noted also trouble in the nasopharynx such as contractures of the muscles of the soft palate and adhesions in the fossa of Rosenmuller.

Misplacements of the uterus have also been found in some cases.

Treatment

Nearly all these cases are curable with from one week to six weeks treatment. Of course the treatment must be intelligently directed after a correct diagnosis as to the cause. The cause can usually be removed. One case to which my attention has been directed was that of a woman about forty years of age who had very severe pains. With all the local treatment of the eye and otherwise she got practically no results until she had replacement of the uterus, which brought immediate relief. Other cases have no trouble on that kind but have lesions of the cervical region and on correction of these lesions the neuralgia disappears. Other cases have had the nasopharynx cleaned out by the finger operation and the stretching of the soft palate which relieved the neuralgia immediately or in a few days. Numbers of cases have been to medical physicians and had various eye remedies administered locally with no permanent benefit. Of course the treatment was administered at the wrong place.

The ramifications of the sympathetic and fifth cranial nerves are so complex and far-reaching that we must keep in mind that one or more of many causes for the trouble may exist and be quite remote from the seat of the pain.

Diseases of the Eyelids

Occasional factors are bee stings or insect bites, which completely occlude the palpebral fissure. We may have some palpebral edema from lid abscesses, chalazion, hordeolum, dacryocystitis, panophthalmia and so forth. In =hemorrhagia subdermalis= there is so much spongy tissue beneath the skin about the eye that the blood extends easily and far. The red tint will soon change to a reddish blue and then become dark, what is known as a black eye (ecchymosis). This frequently results from a blow. The skin is sharply attached around the orbital margin by tense connective tissue so the area of the hemorrhage is limited to the region of the orbit. There may be spontaneous rupture of some of the vessels by hard sneezing or coughing, especially in young children. In older people it may indicate a fragile condition of the vessels, arteriosclerosis or some trouble with the kidneys. The diagnosis of the eye condition is not difficult but the cause of the hemorrhage in that region might be investigated further. Local treatment is of some value in these conditions. They may be soothed by cold compresses. In bee stings and insect bites use an alkaline compress. Manipulation about the eye and osteopathic treatment of the neck with a view to directing a better circulation to that region will aid much.

Herpes Zoster Ophthalmia

This affection of the supraorbital branch of the fifth cranial nerve may extend to the eyelids. It may not go beyond the stage of blistering and redness with some edema. However, it is possible for it to become gangrenous and even extend to the conjunctiva and cornea. I had one case of herpes zoster gangrenosa of this region. There were several gangrenous spots as large as a dime on the forehead and extending down in the region of the eyelid. The process extended to some extent on the cornea and in healing left a condition of irregular astigmatism.

=Treatment.=—The prognosis in herpes zoster is always favorable under osteopathic treatment. Lesions of the cervical region will almost invariably be found interfering with the sympathetic connections of the fifth cranial nerve causing the trophic disturbance to the region. Osteopathic treatment applied to these conditions will always hasten normalization. The affected part might be kept

covered with some soothing lotion to keep the skin soft.

Hordeolum

This is commonly known as a =sty=. It is due to suppuration of the =glands of Zeiss=. It is a harmless affection but causes pain and inconvenience.

=Diagnosis.=—Swelling and pain with a small inflammed nodule in the palpebral margin is quite diagnostic.

=Treatment.=—The circulation is obstructed in this region. The effort should be made to open the circulation before pus has formed. This can frequently be done and the hordeolum aborted by carefully picking up the eyelid and rolling the nodule between the fingers. This will cause some pain but if it is kept up for a moment or two about every hour through the day with an occasional thorough treatment of the neck the sty will usually be aborted. If pus forms it should be opened as soon as it points and then the squeezing and rolling process may be employed again, which will aid rapidly in the freeing of the circulation.

Chalazion

This is a =Meibomian cyst= in the eyelid. It shows as a circumscribed swelling on the inner side of the lid. It frequently becomes large enough to produce some deformity of the lid. A chalazion is movable on the tarsal cartilage. It is a chronic condition and the cyst may become as large as a bean. There may be more than one in the same lid.

=Treatment.=—When a chalazion is small and not of long standing it can frequently be cured by osteopathic treatment. Introduce the finger into the conjunctival sac under the lid, and with the thumb externally, grasp the chalazion between the finger and thumb; roll it thoroughly. Squeeze and massage it two or three times a week for awhile. This, combined with a thorough treatment of the neck, will result in a cure. If at the end of six weeks the condition has not disappeared surgery should be resorted to.

Blepharitis

This is an inflammation of the eyelid. It is either =acute= or =chronic= according to the cause. Acute blepharitis may be due to heat or injury. Chronic blepharitis affects the glands of the lid causing a perversion of the secretions. There is usually the formation of crusts and scales. This condition is known as =blepharitis sicca=. In some cases infection will form little pustules at the roots of the cilia. There is soreness and aching. There may be photophobia. The nasal region may be involved. Osseous lesions of the cervical region are usually present. Refractive errors frequently exist in these cases. Occupation or environment may expose to dust or wind sufficient to keep up the irritation.

=Treatment.=—Change environment. See that there is thorough cleanliness of the lid. Rub or pick away all scales. Use a bland ointment. Correct any cervical or upper dorsal lesions.

Ptosis

This is =congenital= or =acquired=. In congenital ptosis operation seems to be the only treatment. Acquired ptosis is amenable to treatment frequently. The cause is some lesion interfering with the passage of proper nerve force to the levator muscle of the lid. The lesion may be at the origin of the third nerve, at the cortical nucleus in the sigmoid gyrus or in the trunk of the third nerve, or a lesion of the muscle itself. Tumor, trauma, syphilis, sclerosis, hemorrhage, gout or rheumatism, or anything that will produce a peripheral neuritis are causative factors. Lesions of the cervical and upper dorsal by reflecting back upon the nerve centers may produce a ptosis.

=Treatment.=—Remedial measures according to indications. Cases due to osteopathic lesions as indicated will usually yield readily to treatment. Where there are other factors treatment must be varied accordingly.

Trichiasis

This is a condition in which part or all of the eye lashes turn inward and touch the eye ball, due to cicatricial contractions in the conjunctiva and tarsus. Many of the cilia are so small in these conditions that it is very difficult to see them. A loupe or a magnifying glass must be used in order to discover them.

=Dystrichiasis= is a condition where the cilia come in irregularly growing in all directions, some of them turning in toward the eye ball and causing irritation.

=Treatment.=—An epilatory should be used to extract all of the wild hairs. Care should be taken to get out the finest ones as they will frequently cause irritation if not removed.

Entropion and Ectropion

=Entropion= is a turning in of the eyelid and =ectropion= is a turning out. These conditions may be spasmodic and temporary. Entropion is more often due to cicatricial contraction in old blepharitis or trachoma conditions. In some cases the condition may be corrected by the use of strips of adhesive plaster. In cicatricial conditions operation is the rule. Spasmodic ectropion may be corrected sometimes by curing the conjunctivitis. Bandaging may be resorted to. In paralytic ectropion osteopathic treatment may serve to produce a complete cure. Operative procedure should be a last resort.

Diseases of the Lachrymal Apparatus Dacryocystitis

=Dacryocystitis= is an inflammation of the lacrymal sac. It is due to some lesion in the nose, malposition of the inferior turbinate or a poor blood and nerve supply to the lacrymal region as determined by cervical lesions. The sac becomes infected and we have a =dacryocystoblennorrhea.= Pus and tears are regurgitated into the eye through the puncta. There is irritation and the conjunctiva may become infected at any time, also the cornea. It is a dangerous and annoying affection.

=Treatment.=—Osteopathic measures have something to offer along this line. The medical idea seems to be completely surgical in recent years. The first and only thing to be done surgically is to obliterate the sac or dissect it out and curette the nasal duct, completely destroying the apparatus. Lancing does not affect a cure. By treating for a good nerve and blood supply to that region, the irrigation of the nose and a thorough squeezing of the sac each time with a view to forcing the solution in the sac down through the nasal duct into the nose, a cure may be effected in many cases. If these cases can be gotten before infection has taken place, in the state of epiphora or the backing up of the tears into the eye, thorough treatment along the lines just indicated will in nearly all cases result in a cure.

Boric acid solution should be used to wash out the sac when pus is present. The attempt should be made to force it into the nose. Probing properly done is of value in many cases. These cases should be followed up with great care.

Treat the neck thoroughly and spring the inferior maxilla.

Diseases of the Conjunctiva Conjunctivitis

The conjunctiva is a mucous membrane that coats the posterior surface of the eyelids and the anterior surface of the eyeball. It forms a sac, which is slit open in front in the line of the palpebral fissure.

The conjunctiva consists of three parts (1) the conjunctiva tarsi, the part on the lids; (2) the conjunctiva bulbi, the part on the eyeball, and (3) the conjunctiva fornicis, the part connecting the first and second; it is the retrotarsal fold or the region of transition, often called the fornix. The first part can be seen by everting the lids. It is adherent to the tarsus. It is covered with a laminated cylindrical epithelium. The membrane contains an abundance of lymphocytes similar to adenoid tissue. This increases with every inflammation of the conjunctiva. This is why =chronic conjunctivitis= often results in thickened lids.

The =blood supply= of the conjunctiva of the lids is from the muscular branches of the ophthalmic artery. The =nerve supply= is from the ophthalmic division of the 5th cranial and the sympathetic.

The bulbar conjunctiva continues over the cornea. It is covered with layers of pavement epithelium. Its blood supply comes from the posterior conjunctival vessels about the retrotarsal fold, and the anterior ciliary arteries which accompany the tendons of recti muscles; these two systems anastomose in the conjunctiva. Conjunctival injection or congestion shows a superficial net work of larger or smaller vessels that move with the conjunctiva. The color is scarlet or brick red. Ciliary injection occurs as a rose-red or pale violet zone around the cornea, spoken of as peri-or circumcorneal injection. It does not move with the conjunctiva and occurs more with diseases of the cornea, iris and ciliary body.

In the =etiology of conjunctivitis= a great variety of germs are considered by different writers. Collins and Mayo give a report of “germs found in normal conjunctiva.”

Bacillus Xerosis in 94% of normal conjunctivæ; Staphylococcus Albus in 79%; Pneumococcus in 9%; Diplobacillus in 6%; Staphylococcus Aureus in 6%; Streptococcus in 5%.

If this be true, and I do not doubt their statement, we are practically compelled to say that these germs at least are only secondary in the etiology of conjunctivitis. Just at this point osteopathy comes with its flood of light and makes it easily explainable why some conjunctivæ become inflamed while others do not, when all have germs present. The lesion disturbing the integrity of blood supply and nerve force to the eye is the primary cause while the presence of germs may be the aggravating cause. The lesion prepares the soil in which the germs thrive sufficiently to become an irritant. There are all gradations of this soil preparation. The more fertile the field (i. e. the more profound the effect of the lesion) the more virulent germ life may become; the resistance is proportionately less.

=Conjunctivitis= is =classified= for convenience in study, diagnosis and treatment as follows:

(1) Catarrhal, (a) acute, (b) chronic, (c) follicular; (2) gonorrhoeal; (3) ophthalmia neonatorum; (4) trachoma; (5) diphtheritic; (6) eczematosa (phlyctenulosa); (7) vernalis; (8) tubercular; (9) traumatic. This is the clinical classification after Fuch.

Treatment of Conjunctivitis

In order to give the best care in these cases it is quite essential that both the primary and secondary causes be given attention. Some good =germicide= or =antiseptic= is to be used with intelligence. This is in harmony with the great principles of antisepsis and cleanliness taught by osteopathy from its inception. The use of the microscope in the =bacteriology= of conjunctivitis aids in more definite diagnosis and the selection of a proper germicide. For the Koch-Weeks bacillus, the pneumococcus and the influenza bacillus silver nitrate 1% or a 25% solution of argyrol is used; for the diplo bacillus (Morax-Axenfeld) zinc sulphate 1 gr. to the ounce is almost a specific.

A good way to prepare the zinc prescription would be:

Boracic acid and water oz. 1.

Zinc sulphate gr. 1.

The boric acid and water of course being a saturated solution. Apply one drop to each eye about four times a day. If one can not have the use of the microscope to make specific the diagnosis, the zinc solution may be alternated with the argyrol as the germicide. Ice cold applications are good in many of these cases.

Catarrhal Conjunctivitis

=Acute=.—mostly affects the conjunctiva of the lids in the light form. If severe it invades the bulbar conjunctiva. There is redness and swelling and increased secretion which dries at night upon the edges of the lids and glues them together. The eyes are better in the morning and worse toward evening. =Corneal ulcers= and =iritis= may arise as complications. Chronic inflammation may result.

=Etiology.=—Textbooks on the eye give =bacteria= as the chief cause; some scarcely mention anything else. After discussing how the bacteria get there and multiply, they usually bring in some statement to indicate that in many cases no bacteria can be found in the secretions from the conjunctiva. These latter are unaccounted for in the etiology.

=Catarrhal conjunctivitis= is non-specific in its origin.

The great science of osteopathy will fill in the missing links to works otherwise very exhaustive on the eye.

If the cause is due only to a passing irritant as dust, smoke, pollen or wind the disturbance may vary from hyperemia only, to a severe attack of conjunctivitis. Fuch says the majority of cases are produced by bacteria, but THAT IN NOT A FEW CASES OF CONJUNCTIVAL CATARRH THE EXAMINATION OF THE SECRETIONS FOR BACTERIA PROVES NEGATIVE. He also says that the usual course of the disease is from eight to fourteen days, but NOT INFREQUENTLY THERE REMAINS A CONDITION OF CHRONIC CATARRH PROTRACTED OVER A LONG TIME; THAT NOT INFREQUENTLY THE NORMAL CONJUNCTIVAL SAC CONTAINS PATHOGENIC GERMS.

Some authors divide the =etiology= into (1) specific, (2) non-specific. The first they account for by irritants due to dust, heat, smoke, metal, pollen, cold, wind, glare of light, eye strain from overwork of the eyes, ametropia and chronic alcoholism. The second they account for by germ life, most often the Morax-Axenfeld diplobacillus or the Koch-Weeks bacillus, the latter germ being found in the so-called “pink-eye.” It is contagious. This is one condition for which the zinc sulphate (½% to 2% solution) is almost a specific.

No doubt the irritants and the bacteria mentioned, with others, do cause much of our catarrhal conjunctivitis and that one who fails to consider properly the local conditions in practice will be sadly lacking in best results.

On the other hand many cases, treated for local conditions only by very competent men who used the best antiseptics and germicides, have very indifferent results. The acute condition would continue and gradually become chronic. From observation, study and experience there are causes aside from local irritants, ametropia, bacteria, syphilis, rheumatism or measles. There is some disturbance to the integrity of the =spinociliary sympathetic arc=. In many cases of eye disease note lesion and tenderness at the upper dorsal, the removal of which will cause improvement of the eyes. Many cases of eye strain can be relieved by correction of the first, second or third dorsal, and the use of glasses made unnecessary.

Irritation of the eye will cause more or less tension of the muscles at the second and third dorsal, and stimulation of the tissues near the second and third dorsal spines will cause dilatation of the pupils and contraction of vessels of the cranial mucous membranes; which means vasomotor, secretory and trophic disturbances.

It follows then that an =osteopathic lesion= at the second or third dorsal will cause or tend to cause disease of the eye. There may be all gradations in the effect produced, the lighter being mere tendency, while again it may be enough to set up profound vasomotor, secretory and trophic changes in and about the eye. The first effect of the lesion may be stimulatory, and later, inhibitory. The normal resistance of the eye would be lowered and naturally, local irritants, bacteria and ametropia would have a more profound effect. This will explain how one can develop conjunctivitis in the absence of a local irritant with no bacteria present, and no eye strain.

All of these causes, or any number of them, may be acting together, and each more virulent because of the influence of the other.

=Lesions= of the =occipito-atlantal= joint or any of the cervical articulations may cause eye disturbance. There are no efferent ramicommunicantes in that region and the course of the physical disturbance must be greater in proportion to the eye trouble produced, than at the upper dorsal. It is important however to make a close examination of the entire cervical region in eye trouble.

What has been said on the osteopathic causes of acute catarrhal conjunctivitis applies with equal force to chronic and =follicular concatarrhal conjunctivitis.=

What has been said on the osteopathic causes of =acute= catarrhal conjunctivitis applies with even greater force to the =chronic= form. The great variety of local irritants may account for acute conjunctivitis, and does in most instances; but in chronic conjunctivitis local irritants are more often secondary or incidental while the osteopathic lesion with its effect upon the =bulbo-spino-sympathetic= ciliary arc is the =fundamental= cause. Of course some continuous local irritant, e. g., an uncorrected refractive error, excessive light, heat, dust or germ life in the environment may cause a chronic conjunctivitis. Other causes may be retracted lids (lagophthalmus) leaving the eyeballs too prominently exposed; turning in of the cilia (entropion, trichiasis or dystrichiasis) which impinge upon and irritate the bulbar conjunctiva. =Chronic blepharitis= may spread to the palpebral conjunctiva and then the bulbar. Foreign bodies in the eye, or infarction of Meibomian glands may be causes. The diplobacillus (Morax-Axenfeld) is the most common germ in chronic catarrhal conjunctivitis.

=Symptoms and Course.=—In mild cases the redness is only moderate. The conjunctiva is smooth and not swollen. Old cases have hypertrophy with thickening. There was a small girl who came into the office recently who had the conjunctiva of the lids decidedly swollen with some hypertrophy. Her eyes were glued shut with pus every morning. Pus pockets were forming along the follicles of the cilia and on the direct edge of the lid. Her troubles started a year ago and got gradually worse. A few osteopathic treatments were given during three months (she was irregular in coming) and argyrol, 20%, used locally. All pus and debris were cleared off the lids and conjunctiva each time. The swelling all left and the thickening became inconsiderable; the eyes looked almost clear. On pressure there was tenderness at the right side of the second dorsal. No mechanical lesion was apparent there but in treatment that region was thoroughly loosened.

The subjective symptoms are usually worse at night; pain, heaviness of the lids; feeling of a foreign body in the eye; burning; itching and dryness in many cases.

This condition is one of the most frequent of eye diseases in adults; may be senile catarrh in advanced age. It is frequently complicated with blepharitis, ectropion, epiphora and ulcerations of the cornea.

=Treatment.=—The osteopathic treatment depends on the findings in the osteopathic examination. No case of chronic catarrhal conjunctivitis should be treated without a thorough examination of the whole spinal, rib and innominate mechanism. Careful and detailed adjustment should be made of any lesions that might disturb the ciliary arc, the other nerve connections, the blood supply or the body equilibrium.

This does not mean that local treatment of the eye should be neglected in any way. Any measure that will aid in getting rid of local pathology as quickly as possible should be ours. Where there is abundant secretion, silver nitrate 1% to 2% solution put on the conjunctiva with a brush when the lids are turned, or argyrol 20% to 25% dropped into the eye are among the best antiseptics for local use. If the diplobacillus is present zinc sulphate ½% solution is indicated.

The nose, nasopharynx and pharynx should never be overlooked in this disease.

Follicular Conjunctivitis

=Follicular conjunctivitis= is of catarrhal origin. It is characterized by the presence of follicles. There may be only a few or a great many. If numerous they are often in rows on the palpebral conjunctiva. Microscopically they show as circumscribed masses of adenoid tissue. In this they resemble the granules of =trachoma=. Sometimes cases persist for years with little or no inflammatory symptoms. On account of the follicles this disease is frequently confused with trachoma.

We have heard numbers of well meaning conscientious osteopathic physicians testify to curing cases of trachoma with a short course of osteopathic treatment with no pathology remaining. We are absolute believers in the effectiveness of osteopathic treatment and want to give it full credit for doing all it will; but here we want to enter a plea to the profession that we need more discrimination and definiteness in our diagnosis. Technique is being emphasized and we say Amen! It is proper for us to be thoroughly competent in technique but diagnosis should be made just as emphatic because scientific technique depends upon diagnosis for each individual case.

=Differentiation= of follicular conjunctivitis from trachoma.

=Follicular conjunctivitis= occurs (1) chiefly in the young; (2) the follicles are smaller, more sharply limited, project more above the conjunctiva, are often in rows, and oval in shape; (3) the disease clears up with no bad after effects often without any treatment and the tendency is to ultimately get well; (4) it never leads to shrinking of the conjunctiva, to pannus or other destructive sequelæ; (5) it can arise without contagion and is not considered contagious although, like trachoma, it does attack large numbers of people who are confined in a small place.

=Trachoma.=—(1) It seldom occurs in children; (2) the follicles are larger, do not have sharp outlines, are less prominent under the conjunctiva, are round in shape and never in rows; (3) tends to lead to more or less pathology and seldom recovers spontaneously; (4) scar tissue becomes a product of the inflammation in the conjunctiva and leads to shrinking of the conjunctiva, causing in turn entropion and trichiasis. Pannus is the sure result of unarrested cases as there is a tendency to infection of the cornea from the infected conjunctiva moving over it and remaining in contact; (5) trachoma has been proved to be contagious. Trachoma bodies which are considered the infective agent have been isolated.

The use of atropine in some instances will cause a follicular catarrh which clears up on stopping the use of the poison.

Parinauds “Infectious conjunctivitis” has granulations but almost always occurs in only one eye and is accompanied with constitutional symptoms.

=Treatment of Follicular Conjunctivitis.=—The treatment should be directed against the inflammation. The trophicity of the nerve terminals to the conjunctiva may be altered by osteopathic lesions.

Suggestions under chronic catarrhal conjunctivitis apply here. If there is no inflammation the follicles tend to disappear, leaving no trace of pathology, hence a few osteopathic treatments of the lids and the cervical region will hasten normalization.

Gonorrheal Conjunctivitis

This disease is sometimes called =purulent ophthalmia= or =acute blennorrhea=, It is caused from an infection of the conjunctival sac with the gonococcus of Neisser. Contact with soiled fingers or linen may transfer the germ.

=Symptoms.=—Within 12-48 hours after inoculation the first symptoms of redness and irritation occur. This is soon followed by much swelling and tension of the lids and chemosis of the conjunctiva. There is much pain and a copious discharge of pus coming from beneath the lids. At first the pus is yellow or yellowish green.

Later the symptoms begin to subside; there is less tenseness and heat; the lids can be more readily everted and the discharge ceases after 6 or 8 weeks. The puckered conjunctiva becomes rough and granular.

In these cases the =prognosis= is always grave; more so than in ophthalmia neonatorum. The eye is almost always marred in some way. One of the great dangers is involvement and destruction of the cornea. If the cornea becomes hazy soon after symptoms begin it is not a good omen. =Ulcers= will likely form and then there is a tendency to puncture the cornea. In mild cases the cornea may escape without injury. In severe cases it is likely to ulcerate. If it perforates, the anterior chamber is emptied and the iris prolapses into the perforation; adhesions take place and there is healing with reformation partially of the anterior chamber. An adherent leucoma is the result with practical loss of vision. There may be a bulging of the cornea known as anterior staphyloma. The iris and ciliary body may become involved, causing iritis and cyclitis, or the whole inner structures may be affected making a =panophthalmitis= with =atrophy= of the eyeball.

The cornea is affected by the infective material direct or the nutrient vessels to the cornea at the limbus may be obstructed by the extreme swelling and pressure.

=Complications= of arthritis, rhinitis, septicemia and endocarditis may arise. If there is none of these, at least there is a general debilitated condition which needs attention.

=Treatment.=—The treatment should be =local= and =constitutional=, The diagnosis should be made quickly from the history, symptoms microscopically, and local cleansing begun at once and followed diligently. Excessive discharge should be wiped away with cotton. The conjunctival sac should be thoroughly irrigated every hour or oftener if necessary to keep it clean. This is to be done day and night. A saturated solution of boric acid may be used, or corrosive sublimate one grain to the pint, or permanganate of potassium solution 1-5000. The irrigation should be followed by the free use of argyrol 25%. This procedure will keep the eye clean and be the means often of saving the cornea from destruction and the eye from blindness.

If there should be ulceration of the cornea a drop of atropine ½% should be used in the eye often enough to keep the pupil dilated and the ciliary body at rest.

Osteopathic physicians no less than other physicians should not neglect this local, careful, persistent, antiseptic cleansing of the eye in such cases. The osteopathist can do more. He is not limited to antisepsis even in this kind of work, however important it might be. The unaffected eye should be carefully protected. Buller’s shield should be used.

The osteopath should give thorough treatments to the neck and the fifth nerve.

Supporting treatment to the system according to indications should be given e. g., bowels, kidneys, nerves, muscles, joints as in constipation, nephritis, neurosis, rheumatism, arthritis, endocarditis, septicemia, rhinitis etc.

Ophthalmia Neonatorum

This is an =acute purulent conjunctivitis= in the new-born. Neonatorum comes from a junction of the Greek word Neos—new, to the Latin word natus—born; new-born. This disease is the bugbear to the obstetrician. He must always be on the lookout for it and act promptly in order to save sight. Every general practician should make a careful study of this disease if he expects to treat children.

Sixty to seventy percent of conjunctivitis neonatorum is due to the infection with the gonococcus of Neisser. It usually comes from a gonorrheal discharge from the genitals of the mother. The nurse or anyone who handles the baby might be the agent in the transmission of the infection.

The disease is not always of gonorrheal origin. Some cases are due to the pneumococcus, streptococcus, diplobacillus or one variety of staphylococci.

Thus there are two varieties or types of ophthalmia neonatorum; a severe type which is =gonorrheal= or specific and a mild type which is non-specific.

In some states there is a law which requires the use of silver nitrate in the eyes of all babies at birth. Every baby's eyes should be thoroughly washed at birth, with boric acid and where there is the least suspicion of gonorrhea silver nitrate 1% or argyrol 25% should be used. A routine use of one of the silver salts would be good practice.

=Symptoms.=—Gonorrheal cases begin usually the third day after birth, non-gonorrheal, on the fifth or sixth day. Both eyes are usually involved, one worse than the other. The lids swell much. There is chemosis of the conjunctiva which may put the cornea in a pit. The discharge is abundant. It is yellow or greenish yellow.

The disease gradually declines and the discharge ceases in six to eight weeks. The conjunctiva is thickened and looks granular. May be some cicatricial changes.

The chief danger is to the cornea, more so if it becomes hazy the first two days. Corneal lesions seldom occur in non-specific forms.

If the cornea is involved perforation is likely, with a general inflammation of the eyeball (panophthalmitis) followed by atrophy (phthisis bulbi).

Complications such as rhinitis, meningitis, endocarditis and general septicemia may occur.

=Diagnosis= is made from the onset, character, symptoms and course with the use of the microscope.

=Prognosis.=—Delayed or improper treatment in these cases will likely be fatal to sight as sloughing of the cornea will occur. With prompt and proper care the prognosis is favorable.

=Treatment.=—Mild cases (non-specific) are treated in the same manner as simple conjunctivitis. In severe cases (specific) clean the eye carefully and apply cold compresses of gauze 15 to 20 minutes at a time every hour or two. Keep the gauze on a block of ice and change every few minutes. If the cornea is involved heat may prove more satisfactory. There must be constant removal of the discharge. Wipe away the excess and irrigate freely with boric acid at least every hour day and night and more often if necessary. After each washing use a solution of argyrol 25%. Once a day silver nitrate 1% solution may be used and washed out with a salt solution.

If the cornea should ulcerate the treatment need not be altered.

The attendants should be carefully instructed as to the importance of the care and the contagious nature of the pus.

Antisepsis and cleanliness here is more essential, effective and exclusive than in any other disease of the eye. Wisdom in the use of antiseptics is a strong point in the armamentarium of every progressive osteopath.

Trachoma

This disease is known as =granular lids= or =granular conjunctivitis=. Although the germ has not been discovered, we know this is an infectious disease. A roughness and hypertrophy of the conjunctiva develops. There is development of follicles or granulations. Later these products are absorbed and cicatrization of the tissues follows.

=Cause.=—Trachoma is found most common in Egypt and Arabia. It spreads easily in crowded institutions. It is in many instances a mixed infection with the Morax-Axenfeld bacillus, Koch-Weeks bacillus and the gonococcus.

="Trachoma bodies"= have been discovered which are claimed by some to be a causative factor in the disease. These small bodies are not found in all cases however.

Spinal lesions of the cervical and upper four thoracic vertebræ will disturb the blood and nerve supply to the eye which will predispose to the disease should some of the virus or germs of trachoma be present. In practically all these cases there is tenderness if not an actual twist at the second and third thoracic.

=Symptoms.=—A small boy came to our clinics complaining that his left eye was smaller than the right. No inflammation or swelling was prominent. The eye looked normal except slightly smaller than the right. On turning the lid granules in the fornix of that eye

were readily noticed. Trachoma had a good start. The tissues were so hypertrophied in that region that the eye could not be opened quite as wide as the other one, hence the impression that that eyeball was smaller. The granulation often develops so insidiously that the victim may have the disease for months before he realizes he has a bad eye. When symptoms appear there may be photophobia, lachrymation, gluing of the lids from a scanty secretion, pain, and blurring of vision. The granules are gray, translucent and roundish under the conjunctiva.

Hypertrophy increases to a certain height when cicatrization and contraction begin. The duration may be years. The more the hypertrophy the longer the duration and the greater the contraction. (Note here that treatment should be directed toward combatting the hypertrophy by establishing circulation).

=Sequelæ.= I merely mention the sequelæ here: pannus, ulceration of the cornea, trichiasis, dystrichiasis, entropion, ectropion, symblepharon, xerosis, corneal opacities. For the explanation, pathology and treatment of these sequelæ not covered in this treatise, see any good works on diseases of the eye as Weeks, Fuchs or De Schweinitz.

=Treatment of Trachoma.=—In reporting cases of trachoma treated and cured by osteopathy we should be sure of our diagnosis.

The treatment is antiseptic, hydrotherapeutical, osteopathic and operative. A saturated solution of boric acid should be used. Argyrol 20% is good if there is much secretion. Nitrate of silver 2% and copper sulphate are still used in some cases to advantage as claimed by some physicians. The osteopath should count on careful cleanliness.

Hot compresses over the eyes are often very agreeable.

Operations are often performed for trachoma. The granules are rolled out with Knapp's roller forceps, and other methods.

=Grattage= is practiced with some wonderful results. It is done as follows: Get some fine sand paper and cut it in strips about one-half inch wide by three or four inches long. Put it in alcohol in a vessel for ten to fifteen minutes. Pour off all the alcohol except a few drops that will cling to the vessel by capillary attraction. Touch a match to the residue. This will burn just enough to make the sand paper absolutely sterile without burning the latter. Put the patient under somnoform. Use a small artery forceps to grasp the edge of the eyelid, roll the lid back over the artery forceps to expose all granulations clear to the fornix. Use a protector to the eyeball. Now with the sandpaper quickly scrape or curette away all of the trachoma bodies and granulations. Repeat the process on the other eye if it is involved. Wash out well with a saturated solution of boric acid and bandage the eyes for a few hours. This will cause considerable swelling and inflammation. Use cold applications and keep the eyes disinfected. I have seen some very good results from this method.

=Osteopathic.=—Following the sand paper operation a thorough treatment of the cervical and upper dorsal region would add considerably to the rapidity of the patient's recovery and sense of well being. General tonic treatment is of special benefit in nearly all trachoma cases as they are subnormal in their general health.

One form of technique which has been used by myself and others to advantage in these cases is as follows: Sterilize the fingers carefully, lubricate with vaseline or K. Y. the forefinger of the right hand. With the left hand raise the upper lid and introduce the forefinger of the right hand with the thumb above. Catching the lid between the thumb and finger squeeze and massage the whole structure clear to the fornix as thoroughly as possible. Repeat the process on the other eye.

A technique used by Dr. Edwards of St. Louis is as follows: After sterilizing and lubricating the forefinger lift the lid and introduce the finger as far as possible into the orbit pushing the fornix back into the orbit. This stretches all the tissues around the fornix, opening up a better conjunctival and palpebral circulation. The ciliary vessels and nerves are stretched and stimulated. It is rather surprising to one who has not tried it, how far the finger can be introduced into the orbit.

One set of nerves that should be especially studied and considered in trachomatous conditions is the cere-brobulbo-spino-sympathetic-ciliary arc. This has already been elaborated. All spinal lesions should be carefully diagnosed and corrected.

Dr. T. J. Ruddy's third finger eye instrument is very useful in these conditions in restoring normal circulation about the orbit.

See that the nose and throat are normal.

Phlyctenular Conjunctivitis

By some this disease is considered an =eczema= of the conjunctiva. This will at least enable us to get an idea of the conjunctival pathology. What is said of phlyctenular conjunctivitis applies largely to its corresponding disease of the =cornea-phlyctenular keratitis=. Scrofulous ophthalmia is applied by some because so many of these phlyctenular patients have =scrofula=. Herpes conjunctivæ is used as a name because of the small blisters or blebs that form in the beginning stage. Little red eminences develop near the limbus (sclerocorneal junction). They are cone shaped, slightly elevated about the surrounding tissue. There may be one or several, usually not more than one or two. After a few days the cone breaks and on top appears a small gray ulcer. There is further breaking down and the cone disappears leaving an ulcer on level with the conjunctiva. Vessels are congested about it. There may often be noted an area of small vessels, fan like in shape, running from the outer region of the conjunctiva to the ulcer or phlyctenule.

=Etiology.=—This is a disease of frequent occurrence in children, mostly among the poor classes. Such things as eczema, dirt, adenoids, scrofula, rhinitis, malnutrition, abuse of tea and coffee and exanthematous disease are mentioned by oculists as causes. I have no doubt any or all these conditions predispose to phlyctenular conjunctivitis.

De Schweinitz in “Diseases of the Eye,” 1916 edition, p. 242, says: “The exact cause of ocular lesions, or phlyctenular eruption, has not been determined.”

I have met Dr. De Schweinitz and heard him lecture on the eye. I consider him one of the best eye specialists in the country. His experience and study with the eye dates over many years and his book has gone through eight editions. He is professor of ophthalmology in the University of Pennsylvania; Ophthalmic Surgeon to the Philadelphia Polyclinic Hospital, the Philadelphia General Hospital etc., etc.

His opinion represents the summary of the investigation of the ophthalmic profession the world over and through all the past down to the present time. “The cause of phlyctenular conjunctivitis is not known.”

=Bacteriology.=—At times in the ulcers have been found the staphylococcus pyogenes aureus and albus. They are also found in a normal conjunctival sac. They could not with logic be taken as a causative factor; at least they would be only secondary.

If oculists and other students of the eye all had a good deep osteopathic vision to throw light upon these problems many causative factors would take on a new meaning. Such supposed causes as have been mentioned, e. g. eczema, adenoids, rhinitis and malnutrition may easily be secondary to the osteopathic lesions. Micro-organisms may be enabled to act because of trophic and circulatory disturbances to the conjunctiva through disturbed nerve connections from lesions in the cervical and upper dorsal regions. Herpes zoster is purely a trophic nerve disturbance manifestation on the skin as blebs or blisters with more or less neuritis. Any lesion that would affect the integrity of the function of the fifth cranial nerve might easily manifest itself as herpes of the conjunctiva.

We believe the osteopathic lesion is primary and fundamental in the causation of most of our phlyctenular conjunctivitis. Of course insanitation, scrofulous diathesis and the exanthemata play their role. A good diagnostician should figure out the relative importance. The history, onset and examination will usually eliminate these conditions.

=Symptoms.=—Lachrymation, photophobia, blepharospasm and injected vessels are the chief symptoms. There is pain as well as fear of light. The child fights examination.

The attack subsides in ten to fourteen days unless there is multiplicity of blebs. Some patients have repeated attacks for months or years. Many of these cases in medical clinics keep coming for months with repeated attacks. Never leave out careful osteopathic treatment.

=Prognosis.=—This is favorable for a final cure. If there should be multiple blebs and frequent recurrence and the cornea is invaded, the prognosis is not good for perfect sight. The pathology goes deep enough to affect Bowman’s membrane of the cornea disturbing the substantia propria. This causes a macular condition of the cornea which impairs sight.

=Therapy.=—Diet should be bland; the eyes should be protected from irritants; yellow oxide ointment should be used in the eye once a day or 10% argyrol. The ointment is preferred. Moist warm compresses on the eye are comforting. A boric acid wash in almost all conjunctival trouble is good. If there is much irritation giving a suspicion of iris involvement a drop of atropine ½% should be used. The general regimes of living should be regulated.

Osteopathic treatment should be directed toward building up the general health and correcting all lesions, especially that may have a specific bearing on the eye trouble. Such lesions will be found more often at the first, second and third thoracic, but may be anywhere from there to the occiput.

Vernal Conjunctivitis

This disease is known by many as =vernal catarrh= or =spring catarrh= of the conjunctiva. It is a chronic inflammation which sets up changes in the conjunctiva and tarsus. This disease may be confused with trachoma unless one observes closely. There are broad flat papillæ on the conjunctiva. These papillæ may readily be taken for granulations. They are larger than the granules in trachoma. They somewhat resemble the arrangement of cobble stones. The conjunctiva has a bluish-white filmy appearance called by some, milky shimmer.

The disease was thought at first to appear only in the spring, hence the name vernal. Many cases continue through the year with exacerbations in the spring. It occurs more often in boys. Both eyes are attacked. It may heal and leave no trace. It may last from four to twenty years.

=Causes.=—Almost all works on the eye say the cause is not known. De Schweinitz says, “Definite information in regard to the cause of this disease is lacking.” There may be a micro-organism which has not been discovered.

I wish to call the attention of the osteopathic profession to the great fact that there are numbers of diseases of the eye as well as of other parts of the body about which the medical profession are entirely “at sea.” This gives valuable ground for scientific research by our profession.

My experience with this disease is not sufficient for me to speak with any positiveness or finality as to its cause. The altered trophic parts and the very chronic condition existing leads me to the firm belief that we will ultimately find the cause as a mechanical lesion affecting the trigeminal or sympathetic (or both) nerve connections. Glare of light and local irritants act only as secondary causes. Nasal disease may be associated and act as a cause.

=Symptoms.=—There is photophobia, some mucus, slight pericorneal injection, redness of the conjunctiva of both the bulb and lids; that of the lids is thickened and of dull pale color due to sub-epithelial hyaline thickening. The fact that there is no pannus, and flat granulations and recurrence with spring, marks it from trachoma.

=Prognosis.=—Under medical treatment it is unfavorable; may last twenty years. Slight opacity of the cornea may develop.

=Treatment.=—The eyes should be protected with dark glasses. Cold compresses give some relief. Boric acid is good as a wash. Yellow oxide of mercury ointment may be of service as an antiseptic and alternative. If nasal disease exists, it, of course, should be treated according to indications. Fundamentally the lesions in the spine in the cervical and upper dorsal regions should be specifically corrected. When enough cases of vernal catarrh have been observed and treated osteopathically much light and benefit will be brought to bear upon this obscure and intractable disease of the conjunctiva.

Diseases of the Cornea

Anatomy

The cornea with the sclera forms the outer coat or tunic of the eye ball. The cornea is in front and forms one-sixth of the envelope. It is a segment of a smaller globe than that of the sclera. It is about 12 mm. horizontally and 11 mm. in the vertical diameter. Its thickest part is at its junction with the sclera where it is about 1 mm. This junction is called the limbus. The cornea is inserted into and rests on the sclera like a watch crystal. The fibers of the cornea pass continuously into the sclera, however. The normal cornea is transparent. Most morbid changes of the cornea cause a diminution in this transparency. In old age a narrow gray line near the corneal margin makes its appearance. This is known as the =arcus senilis=. There is a little strip of perfectly clear cornea between the arcus senilis and the limbus.

The cornea has five layers. These layers should be noted with care, as in wounds of the eye, foreign bodies in the cornea and ulcerations, the results depend much upon which layers are affected.

1. The =anterior epithelium= consists of pavement cells of several layers. This layer of the cornea may be damaged or scratched off in large patches and still it will heal readily leaving no trace of the injury.

2. The =anterior elastic lamina= or =Bowman's membrane= is very thin and homogeneous; it is just beneath the epithelial layer and forms a resisting sheath to prevent damage to the next layer.

3. The =stroma= or =substantia propria=. This layer composes about nine-tenths of the cornea. It is composed of minute connective tissue fibers between which lie some stroma cells or corneal corpuscles. Some of these cells are fixed while others are motile. The motile ones are the white blood-corpuscles which move about in the lymph passages of the stroma. They increase in any irritation of the cornea.

4. =Descemet's membrane.= This is a tough homogeneous hyaloid membrane back of the stroma. When the stroma is diseased and breaks down Descemet's membrane may be sufficient to prevent a puncture of the cornea.

5. The =Endothelial layer= is a single layer of flattened cells which coat the posterior surface of Descemet's membrane.

The margin of the cornea is in relation with three membranes, the conjunctiva, the sclera and the uvea (iris and ciliary body). In a disease of the cornea, a conjunctivitis, an iritis or a cyclitis is easily started.

The cornea contains no vessels. It is nourished by imbibition. At the limbus there is a rich network of marginal loops supplied by the anterior ciliary vessels. From these loops the blood plasma passes into the stroma of the cornea.

The nerves of the cornea come from the ciliary nerves and the nerves of the bulbar conjunctiva. These are from the trigeminus and the sympathetic. The nerves extend numerously in the stroma passing forward through Bowman's membrane into the epithelial layer. This makes the cornea very sensitive to the touch.

Examination of the Cornea

Note the size and form. Both may be modified by morbid processes. Note the surface with regard to curvature, evenness and smoothness. In =keratoconus= the curvature is greatly increased. Noting the reflex images in the cornea and comparing these with those of a normal cornea will show any variation in curvature. Also any =unevenness of the surface= may be noted by the irregularity or distortion of the images. Uneven spots on the cornea may be =depressions or elevations= from loss of substance; =wrinkles or collapse= from lowered tension.

If the smoothness or polish of the cornea is lost it looks like glass that has been breathed upon or greased. It is lusterless and dull.

Note also the transparency of the cornea and determine the form, extent and density of the opacity; whether it is diffuse or in spots; in the deep or superficial layers. A magnifying glass should be used in the study of opacities. According to the density of the opacity of the cornea it is known as a =nebula= or a =nebulous opacity=, a =macula= or a =leucoma.= The nebula is the least noticeable and the leucoma is the densest opacity. A leucoma is a condition of complete opacity. The cornea looks white.

Defects in the corneal epithelium may be made to show clearly by the use of a 2% solution of fluorescein which stains them green.

Note the sensitiveness of the cornea by touching it with the end of a thread, a little cotton or a shred of paper. The sensitiveness is diminished or lost in glaucoma and some other diseases.

Diseases of the Cornea

Almost all diseases of the cornea have some form or degree of inflammation. =Keratitis= is the word generally used for inflammation of the cornea. In order to aid clearness in discussion there are various subdivisions of keratitis made by different writers. Suppurative and non-suppurative are the principal types. In =suppurative keratitis= there is always some destruction of corneal tissue which on healing leaves an opacity with partial loss of vision. Germs gain entrance into the tissues usually from the exterior and some form of ulceration results.

The following classification is taken from Fuchs:

=Suppurative Keratitis.=—(1) Ulcer of the cornea; (2) Serpiginous ulcer; (3) Keratomalacia or Xerosis; (4) Keratitis neuroparalytica.

=Non-suppurative Keratitis.=—(A) SUPERFICIAL: (1) Pannus, or keratitis with blood vessels; (2) Phlyctenular, or keratitis with vesicles. (B) DEEP: (1) Parenchymatous or interstitial.

In keratitis there is first an infiltration or the increase of cells in the substantia propria or the parenchyma of the cornea. This is the exudate of the inflammation. It causes the cornea to look more or less dull or cloudy. The disease may clear up at this point or go on to suppuration. If it clears up it is known as =resorption=. If the lamellæ of the substantia propria are not destroyed by the process, resorption takes place with no loss of substance. The exudate disappears and there is perfect transparency of the cornea again. There may be slight damage of the stroma preventing perfect transparency. Resorption of the exudate may not be quite complete which may become partly organized and left permanently fixed in the cornea. Cases resorbing without destruction of the stroma are forms of the non-suppurative keratitis group.

If the stroma breaks, suppuration occurs. This is the second stage and is associated with a localized destruction of the cornea. These cases are known as =suppurative keratitis= or =ulceration of the cornea=. The disintegration begins in the most anterior layers of the cornea. A slight depression in the cornea can be noticed. The infiltration is all about the ulcer, getting less as it is more remote from it. If the floor and walls of the ulcer are foul with the infiltrate it is known as a =progressive= ulcer. =Sloughing= may continue to spread the ulcer.

If the cloudiness around it disappears and the ulcer acquires a smooth transparent base and edges it is known as a =retrogressive= or clean ulcer.

The disintegrated areas of the cornea may be replaced by newly formed tissue. This is the third stage or that of =cicatrization=. This new tissue is connective tissue. It is opaque, leaving a permanent opacity.

=Stages of keratitis=:

=Suppurative.=—(1) Infiltration; (2) Suppuration and (3) Cicatrization or Reparation. The suppuration is progressive or retrogressive.

=Non-suppurative.=—(1) Infiltration; (2) Resorption.

In the diagnosis of a keratitis one should look at it very carefully. A loupe which has thick plus sphere lenses will magnify the field and may be of great assistance in observing closely the condition.

If the cornea is clouded and dull the trouble is recent and if there is no loss of substance it is an infiltrate (first stage). If there is loss of substance it is a progressive ulcer (second stage.)

If the surface is lustrous but cloudy the trouble is an old one and if there is loss of substance it is a retrogressive ulcer; if no loss of substance it is a cicatrix.

Frequently blood vessels grow in from the margin in ulcerations of the cornea. This is usually a process of healing of the corneal ulcer. The advent of the blood vessels is favorable. After healing the blood vessels gradually disappear. They never entirely disappear from large cicatrices.

In some cases new vessels accompany the inflammatory process and like the exudate are a part of the clinical picture of the disease as in parenchymatous or interstitial keratitis. Pannus also has vessels. They are not in the cornea but are in new tissue deposited upon it.

=Symptoms appearing in keratitis=:

1. =Ciliary injection= or a red area encircling the cornea. If the keratitis is severe there will be considerable inflammation of the conjunctiva which may hide to some extent the ciliary injection.

2. =Iritis or iridocyclitis= may set in. The iris and ciliary body are in such intimate relation with the cornea that these structures are very subject to involvement in any severe keratitis. With iritis would come danger of =synechiae= or adherence of the iris to the anterior surface of the lens.

3. =Hypopyon.=—In suppurative keratitis there is some exudate into the anterior chamber of the eye. This exudate drops to the bottom of the chamber and looks like pus had gathered in the bottom of the aqueous. This condition is called hypopyon.

4. Other symptoms which are frequently prominent are =diminished vision=, =pain=, =photophobia=, excessive =lachrymation= and =blepharospasm=. Edema of the lids and conjunctiva may occur.

Intelligent treatment of keratitis of course is based upon the exact conditions present. Great care in diagnosis and treatment should be exercised.

Ulcer of the Cornea

Inflammation of the cornea sets in from some cause. There is an infiltrate into the substantia propria. A spot becomes cloudy and the surface over it becomes dull; at this point the epithelium breaks down or exfoliates and the loss of substance in the parenchyma is the beginning of an ulcer.

=Cause.=—The cause may be constitutional or local. The causes usually thought of from the medical standpoint may be noted in such books as “Diseases of the Eye” by De Schweinitz or Weeks. I wish especially to call attention to the fact that there is frequently a primary and underlying cause of corneal ulcers not mentioned in any medical texts, i. e. the osteopathic lesion. By this I mean more than the spinal lesion although the subluxation lesions that result from the occiput to the fourth dorsal are of most importance. Any tension or change of tissue in the cervical region that may interfere with perfect freedom of circulation of blood to the tracts and centers in the cord, is to be considered. The osteopath of course should take into consideration all causes primary and secondary and govern himself accordingly.

=Symptoms and Course.=—There is a gray area surrounding the ulcer at first, also the floor is grayish in color. In this condition it is known as a =progressive= ulcer or a =foul= or =unclean= ulcer. This cloudiness or gray area may increase in size and the ulcer keep spreading, or it may go deeper even to perforation of the cornea.

Some ulcers advance or spread on one side and heal on the opposite side so that they creep along on the cornea—these are the so-called =serpiginous ulcers=.

With corneal ulcers there is irritation, pain, photophobia and increased lachrymation. There is usually some ciliary injection which is an indication of involvement of the iris and ciliary body. If iritis occurs there is contraction of the pupil with slow reaction. =Hypopyon= may develop. With iritis and the exudate there is likely to be adhesions between the iris and the lens known as posterior synechia.

A few corneal ulcers are asthenic and do not have irritative symptoms and yet are dangerous.

When the ulcer begins to heal it is called =retrogressive=. Dead tissue is cast off; other tissue becomes transparent from resorption. We have a =clean= ulcer. Symptoms disappear and cicatrization begins. Vessels extend to the ulcers and soon it is leveled up with the corneal surface. Cicatrization may leave it slightly below the corneal level or above it.

If there should be perforation of the cornea from the ulcer there may be =complications=, e. g. keratocele, loss of aqueous, dislocation and expulsion of the lens, intra-ocular hemorrhage, flattening of the cornea, fistula of the cornea, glaucoma, intra-ocular suppuration, prolapse of the iris into the opening, etc. These complications and sequelæ that occur occasionally will not be considered here.

After healing is complete by cicatrization there is opacity of the cornea in proportion to the depth and size of the ulcer. In months and years of time there is some clearing of the opacity so that small superficial opacities may become invisible.

=Treatment of Corneal Ulcers.=—Most ulcers of the cornea are quite amenable to proper treatment and the prognosis is favorable. Neglect or wrong treatment is very dangerous. The treatment is local and constitutional. Often the ulcer is kept going by unwholesome constitutional conditions.

=Local Treatment.=—This varies according to the stage of the ulcer, whether progressive or retrogressive. In a progressive or foul ulcer if due to trauma any foreign bodies should be removed. If the ulcer is a result of pathology of the conjunctiva it is of primary importance to treat the conjunctival condition.

In mild cases of ulcer a dressing over the eye with atropine ½% to keep the pupil dilated is sufficient local treatment. The bandage protects the eye from bright light and other environment and the atropine puts the iris and ciliary body at rest preventing complications and giving nature her best chance to work.

If the ulcer is rapidly progressive, warm compresses an hour or two a day are good; iodoform sprinkled on the ulcer or actual cautery may be used. In the retrogressive stage (clean ulcer) healing has begun and we desire to get as near as possible a

resistant transparent cicatrix. Yellow oxide ointment is useful at this stage.

=Osteopathic.=—The local measures just mentioned are not incompatible with osteopathic theory or practice. They are merely adjunctive in getting nature's reaction toward normalization, as also are hot and cold applications. Osteopathy comes in now in a most important and fundamental way with the constitutional and specific lesion treatment. The =bulbo-spino-sympathetic-ciliary arc= has been mentioned and explained. Through this important nerve connection with the eye, profound and wholesome effects on the eye may be gotten by osteopathic treatment. Frequently lesions of the occiput, cervicals and upper dorsals will affect the integrity of the ocular structures through disturbances of nerve and blood supply.

The stomach, bowels, liver and kidneys should be carefully noted in corneal ulcers. Poor circulation, indigestion, constipation and auto-intoxication may have an important bearing on the recovery of the ulcer.

Xerosis or Keratomalacia

This is a disease of the eye in children due to insufficient nutrition of the cornea. Hereditary influences, depleting diseases and lesions affecting the trophic nerves to the eye are causes.

=Treatment= consists of building up the nourishment of the child, correction of lesions and careful dieting. Hot applications to the palpebral region helps to bring the blood supply to the eye for local effects.

Keratitis Neuroparalytica

This disease is due to a paralysis of the 5th cranial nerve. The cornea becomes slightly cloudy. The epithelium gradually sloughs away. An ulcer may or may not form. Pain and lachrymation are absent because of paralysis of the trigeminus. There is usually ciliary injection.

=Treatment.=—The most important treatment for this unfortunate condition is manipulation to restore the integrity of the 5th cranial nerve and the blood supply to the eye. Cervical, spinal, nasal, nasopharynx treatment should be given. Spring the inferior maxilla.

A drop of atropine (1%) should be used locally because of the ciliary injection. Warm compresses used locally will help. The healing usually leaves some opacity of the cornea. Keep the eye bandaged to protect the cornea.

Pannus

This form of keratitis is superficial and is characterized by the formation of blood vessels in the cornea. It is caused by some irritative influence. Most often it is a complication of trachoma.

If the irritation can be removed the vascularity gradually recedes, leaving a clear cornea unless the deeper structures of the cornea have been involved.

Phlyctenular Keratitis

This disease is an involvement of the cornea with an eczematous process similar to phlyctenular conjunctivitis. There is more likely to be ciliary injection and iritis, in which case atropine should be used. The treatment is the same otherwise as for phlyctenular conjunctivitis.

Parenchymatous or Interstitial Keratitis

This is shown by a diffuse inflammatory infiltration of the substantia propria of the cornea. Part or whole of the cornea of one or both eyes may be involved. Very fine blood vessels may invade the deep structures of the cornea.

=Cause.=—Syphilis, tuberculosis, rheumatism, diabetes and rachitis are systemic diseases found back of this trouble.

=Symptoms.=—Irritation, lachrymation, photophobia with ciliary injection are the chief symptoms.

=Treatment= must be local and constitutional.

Locally atropine should be used. Dark glasses should be worn or the patient must be kept in a dark room. Treatment to the trigeminal nerve and tissues of the orbit should be given.

Constitutional treatment should be spinal with the idea of arousing all the forces of the body to greater activity. Careful dieting should be followed according to indications.

The infiltration and blood vessels will ultimately disappear. Sometimes enough may remain to cloud the vision.

Diseases of the Iris and Ciliary Body

The iris and ciliary body have the same blood and nerve supply. That is, they are supplied by the same set of vessels and nerves. For this reason it is practically impossible to have an iritis absolutely independent of a cyclitis or some inflammation of the ciliary body. If the iris is the primary seat of the trouble there are certain symptoms that may indicate such a state. However, when we are treating the iris or diagnosing conditions of the iris we must remember that the ciliary body is very likely more or less involved and may be the primary seat of the trouble.

In =iritis= there are some symptoms which are caused from the hyperemic condition of the eye, such as a slight change in color. The pupil becomes rather inactive, there is some ciliary injection with photophobia, lacrymation and pain. In case of an exudate in the iris there may be thickening, and the exudate in the anterior chamber of the eye will form a =hypopyon=. Sometimes the small vessels will break and there will be a little bleeding which will be mixed with the debris in the bottom of the anterior chamber. This is known as hyphemia. There are likely to be adhesions between the iris and the anterior capsule of the lens known as posterior =synechia=. The pupil is more or less irregular. If atropine is dropped into the eye to dilate the pupil, parts of the edge of the pupil will be adhered while the other parts dilate making it very irregular.

In case of cyclitis there is an exudate from the ciliary body into the posterior chamber. This may cause a total adherence of the iris to the crystalline lens. With the ophthalmoscope, opacities in the vitreous may be noticed. These are exudates. The tension of the eye is liable to increase a little at first but as the exudates absorb there is more or less softening. Vision is low. Also in cyclitis there is ciliary injection, photophobia, lacrymation and pain, similar to that of iritis. Pressure on the eye ball will reveal a very tender condition around the sclerocorneal junction or over the area of ciliary injection.

The causes of iritis, cyclitis or iridocyclitis frequently are systemic conditions and infection such as syphilis, rheumatism, gonorrhea, tuberculosis, infectious diseases and metabolic changes, it may be of traumatic origin or sympathetic. Fuchs says “There are many cases of iritis for which no cause can be discovered and therefore which cannot be placed under these causes.” We agree with him and advance the theory of cervical and upper dorsal lesions or trouble in the sinuses, nose, nasopharynx or throat. No doubt osteopathy can throw some important light on the causes of diseases of the iris and ciliary body. The nose and throat should be examined in all these cases.

=Treatment.=—Atropine must be used in the sore eye to put the iris and ciliary body at rest and dilate the pupil to draw it back from the lens so that adhesions may not form. Warm compresses will give much comfort. Sweating should be brought about. All fluid should be reduced to a minimum. Diet should be very moderate and the bowels kept unusually free. The eye should be protected by dark goggles. Thorough treatment of the neck and upper dorsal region with attention to the nose and throat should be given. Constitutional treatment should be given according to the indications mentioned under causes. If annular synechia or total posterior synechia form or there is atrophy of the eyeball operative work may be needed. Also for injuries, tumors, anomalies and so forth of the iris see the latest medical works on this subject.

Diseases of the Choroid

The =choroid= is the vascular tunic of the eye. With the iris and ciliary body it forms the =uvea=. The iris and ciliary body are rich in nerve terminals and when inflamed; pain is a prominent symptom. The choroid has no sensory nerve terminals. When it is involved alone; pain is not present however severe the pathology. Embryologically Descemet’s membrane is a part of the uvea. When the uveal tract is diseased we frequently note symptoms of a descemetitis as a turbidity of the anterior chamber and spots on Descemet’s membrane. When one part of the uvea is inflamed the tendency is to pass to the other parts because of the intimate blood supply.

Choroiditis

There are many forms of choroiditis given by writers according to the clinical picture and the pathology.

=Symptoms.=—No pain is experienced unless there are complications. Vision is altered in some degree. The use of the ophthalmoscope may reveal opacities in the vitreous. Pigmentation spots and exudation may be noted in the fundus. In disseminated choroiditis spots of exudate appear in the fundus which go on to atrophy, leaving irregular circular light patches.

=Treatment.=—In all forms of choroiditis careful diagnosis of constitutional conditions should be made and treatment given according to indications.

Nasopharynx and orbital treatment as outlined under manipulation for diseases of the eye should be given.

Rest and protect the eyes. Secure free elimination.

Panophthalmitis

By injury or otherwise pathogenic germs are introduced into the eye. The trouble begins as a =suppurative choroiditis= and rapidly spreads to all the eye structures. The vitreous chamber becomes filled with pus.

=Symptoms.=—Pain is severe and sight is lost early. The conjunctiva and lids are much swollen. There is a mucopurulent discharge. The cornea becomes gray and may slough. In about two weeks the inflammation subsides and the globe passes into atrophy.

=Treatment.=—Elimination must be thorough. Spinal treatment for keeping up strength. Cervical, upper dorsal and nasopharynx treatment for the eye. Moist hot compresses to the eye. Operation, incision for drainage, or evisceration may have to be performed.

Sympathetic Ophthalmia

The other eye may become inflamed by the process from the panophthalmitis passing around through the circulation or the continuous structures. All symptoms of a general inflammation appear and vision gradually diminishes.

=Treatment.=—In panophthalmitis of one eye always watch the other eye closely. If it becomes irritable or shows any signs of being affected the diseased eye should be promptly removed, especially if vision is lost in that eye. If no irritation occurs, continued conservative treatment of the panophthalmitis may result in a subsidence of the disease without the well eye becoming affected.

Sympathetic inflammation rarely develops earlier than a month after injury to the exciting eye. Sooner than that or even a few minutes after injury there may be some signs of sympathetic irritation and the symptoms continue with no evidence except a slight circumcorneal injection. It should be treated like iritis. A thorough toning of the system by spinal treatment should be given. Order a limited diet. Secure free elimination.

Glaucoma

Glaucoma is essentially an increase in the intra-ocular pressure. All other symptoms of the trouble may be traced to this condition.

In =Primary Glaucoma= the increase in pressure sets in without any discoverable antecedent disease of the eye.

In =Secondary Glaucoma= the increase in pressure is due to some other disease of the eye. It is a symptom, a complication or accessory and is confined to the eye diseased.

Primary glaucoma affects both eyes, but not always at the same time. Fuchs says primary glaucoma constitutes about 1% of all eye diseases. It is often mistaken for iritis or iridocyclitis and treated with atropine which is contraindicated. It may be regarded as beginning cataract and time lost in expecting it to become ripe. These delays and wrong treatment have caused much blindness.

Palpation with the finger or the use of the tonometer may readily detect any increase in tension. A correct diagnosis must be made early and proper treatment instituted if vision is to be saved.

=Primary glaucoma= may or may not have signs of inflammation. If the tension rises suddenly inflammatory symptoms develop (acute) while if the increase in tension develops gradually these symptoms are lacking (simple).

=Acute primary glaucoma—Symptoms.=—First stage, rise in tension, vision obscured, sees a colored ring around lights, cornea dull, pupil dilated and sluggish, some ciliary injection. The attack may clear up for a day or for weeks. Gradually the symptoms become permanent after repeated attacks. Second stage, when the attack comes there is much pain, visual power fails rapidly,

may be edema of the lids and chemosis of the conjunctiva, all symptoms become much exaggerated, the cornea becomes cloudy. After a violent attack the vision is more or less permanently damaged. Third stage, after many attacks the optic nerve becomes excavated and atrophy takes place.

Simple Primary Glaucoma

=Symptoms.=—Tension comes gradually; no inflammatory signs; pupil somewhat dilated and sluggish, the cornea may look slightly smoky. With the ophthalmoscope a cupped disc may be noted. There is gradual diminution of sight, which begins by contraction of the field.

There are many theories advanced as to the cause of intra-ocular tension in glaucoma. (Fuchs, Weeks, De Schweinitz).

=Treatment.=—Eserine is used instead of atropine. The object is to contract the pupil and draw it away from the side wall of the eye ball so the sinus (Schlemm's canal) and the pectinate ligament (the filtering angle) may become free. The good effect of this is more marked in inflammatory glaucoma. In simple primary glaucoma miotics do little good.

Reports from osteopathic treatment of this condition have been favorable in a number of cases. Careful manipulation of the structures of the orbit with the finger or with Dr. Ruddy's third finger eye instrument is good in restoring better circulation of the lymph and blood. Special attention to the venous drainage should be given. Treat the points of the fifth nerve, the nasopharynx and cervical region, spring the jaw. Treat second dorsal.

Have the patient avoid strong emotions or excitement. Keep the bowels free and use only a very bland diet.

Iridectomy is considered the best operation in glaucoma.

In the treatment of secondary glaucoma the other diseases or complications must be considered in conjunction with the foregoing treatment.

Diseases of the Lens

Opacities or Cataract

=Symptoms.=—Beginning opacities can best be recognized with the ophthalmoscope. Advance opacities can be seen at a glance with the naked eye.

Vision is disturbed according to degree and location of the opacity. If the opacity is in the center of the lens and the periphery is transparent they see better when the pupil is dilated. When the opacities are in the periphery of the lens they see better by day. Muscæ volitantes and polyopia are present until increasing opacity closes up all clear areas shutting out these visual perversions.

There are many clinical varieties of cataracts which may be studied in works on ophthalmology.

=Causes.=—Some interference with the nutrition of the lens accounts for the condition. Heredity is supposed to play a part in some cataracts. Rickets, convulsions, traumatism, old age, some drugs (ergot), inflammation of iris, ciliary body and choroid are given as causes. Cervical and upper dorsal lesions and disease of the throat, nasopharynx and nose will interfere with perfect circulation and drainage of the orbit, and may well have much to do with many idiopathic cataracts.

=Treatment.=—Many cases have been reported cured by osteopathic measures. Correct lesions and treat to establish free nerve force and circulation of blood and lymph to the orbit. Manipulation of the orbital tissues and mild vibration of the bulb are measures of value. More hope may be held in symptomatic, toxic, secondary and progressive cataracts. The process may be stopped and in many cases there is hope of a clearing.

Diseases of the Retina

The retina lines the back part of the eye ball. It comes forward to the ora serrata. It consists of ten layers which have been demonstrated microscopically. One layer of it passes over the ciliary body and back part of the iris to the pupil. The fibers of the optic nerve spread out over the retina. The point of entrance of the optic nerve is the papilla. It is to the inner side of the posterior pole of the eye. The retinal vessels emanate there. The macula lutea is the yellow sensitive spot at the posterior pole of the eye. The fovea is the center of the macula. The rods and cones constitute the external layer of the retina. This layer is the light

perceiving stratum. For vision to be perfect all the other layers must be perfectly transparent. The visual purple is a chemical substance in the rods that gives the retina a purplish-red color. The light shining into the eye forms images which are converted into nervous stimuli by chemical action of the visual purple and by physical changes and fibrillations in the rods and cones.

Retinitis

=Symptoms.=—The ophthalmoscope must be used in diagnosis. There is at first cloudiness of the retina; the outlines of the papilla become indistinct. We may note light patches of exudates. The vessels are more tortuous and often there are hemorrhagic spots. Opacities in the vitreous due to the exudate may be seen. Vision is disturbed in proportion to the inflammation. Weeks or months are required for recovery. Atrophy may set in and cause blindness.

=Cause.=—Many general diseases are found back of this trouble, e. g. albuminuria, diabetes, leukemia, syphilis, gout and arteriosclerosis. Idiopathic cases occur with none of these diseases present, which gives a field for osteopathic research.

=Treatment= should be directed against the general disease when present. For local effects treatment should be given to all the centers and localities that affect the trophism, nerve supply and circulation to the eye. Protect the eye by dark glass or confinement to a dark room and complete rest. Keep the bowels free and produce diaphoresis.

Optic Neuritis

This disease when manifest in the eye ball is called papillitis. If back of the bulb it is =retrobulbar neuritis=.

=Symptoms of papillitis.=—Pupils are dilated and sight diminishes. The color of the papilla is altered to a white, reddish or gray and may show extravasation of blood. The papilla is swollen (choked disc), the arteries are thin and the veins are engorged. It takes months for the inflammation to clear. Atrophy is likely to occur.

=Causes.=—Brain diseases are the most frequent cause, e. g. tumors. Syphilis, febrile diseases, nutritive disturbances, lead poisoning, heredity and growths in the orbit are cited as causes.

=Symptoms of Retrobulbar Neuritis.=—There is little or no change in the papilla. The diagnosis must be made mostly from the way the vision is affected. The rule is a central scotoma in the field of vision. The first colors to disappear are red and green. In the acute form there is quick disturbance of vision. The eye looks normal outside and shows practically no change inside.

=Cause.=—Toxemia, cold, influenza; nasal, nasopharyngeal and sinus disease (ethmoids), and infectious diseases are causes. Idiopathic inflammation of the optic nerve is noted by most oculists. Here the profound effects of spinal lesions upon the eye adds some important light.

=Treatment of Papillitis and Retrobulbar Neuritis.=—In each individual case the treatment requires consideration of the causal factor. There may be required constitutional treatment in many cases. In others the cause may be found in the nose, nasopharynx, or spine. Effort should be made to remove the lesion in each case. Diaphoresis will aid in acute stages.

Atrophy of the Optic Nerve

There are many causes for this condition such as optic neuritis, meningitis, acute infectious diseases, locomotor ataxia, arteriosclerosis, nasal disease, syphilis, traumatism, alcoholism, exposure, embolism of the central retinal artery, diabetes and poisoning. Diagnosis must determine the original cause.

=Treatment.=—I have mentioned conditions in the nose as frequently accounting for various eye troubles. If these atrophies of the optic nerve can be gotten early, many of them will be influenced very favorably by osteopathic treatment. Spinal treatment to direct the circulation to the area of the orbit at the base of the brain is beneficial. Regulation of the patient’s diet, habits, methods of living and so forth is important. Excessive mental strain, excessive sexual intercourse and stresses of every kind should be prohibited. Special treatment should then be given according to the causal factors entering into the case.

Eye Strain and Its Reflexes

For the subject of refraction and refractive errors such as the different forms of hypermetropia, myopia and astigmatism the reader is referred to the many excellent works on ophthalmology which cover these subjects quite thoroughly. They are only used here in the relation to eye strain and its reflexes. The osteopathic logic here given should be combined with a reading of the refractive

errors in such works as Fuchs, Weeks, De Schweinitz and others.

Asthenopia

=Eye strain, weak sight or asthenopia= embraces the group of symptoms dependent upon fatigue of the ciliary muscles or of the extraocular muscles.

There are three varieties of asthenopia. (1) Retinal or nervous, (2) muscular and (3) accommodative.

The symptoms are headache—frontal, fronto-temporal or fronto-occipital. It may extend into the neck between the shoulders. Eye balls may be tender, diplopia at times, may be photophobia, lachrymation, congestion of the eye, itching and burning of the lids.

=Accommodative Asthenopia.=—In this form the ciliary muscle is fatigued. The cause is usually overuse of the eye when hyperopia and astigmatism exist; sometimes in myopia or presbyopia.

=Treatment.=—In this form the treatment is the proper fitting of glasses and improvement of the general health.

=Muscular Asthenopia= is due to tiring of the extraocular muscles, usually the internal rectus. This may result in a phoria or a non-paralytic squint.

Ametropia may exist but asthenopia may come even in emmetropia due to overuse of the eye.

=Treatment.=—Correct ametropia if present, with glasses. Exercise the weakened muscle. Correct the nerve supply to the weak muscle. Treat cervical and upper dorsal. Manipulate tissues of the orbit. Spring the jaw. Correct any nose and throat pathology.

=Nervous, Neurasthenic or Reflex Asthenopia.=—The cause is supposed to be some functional disorder, more often found in females. May be due to too dim or too bright light, overuse of the eyes. Hysteria may follow ametropia.

=Treatment.=—Often the treatment is troublesome and the case is very obstinate according to old school methods. Rest, hygiene, general health and habits are looked after. The cause must be found or the treatment cannot be specific.

These are the different forms of eye strain as ordinarily classified. Now as we study the reflex symptoms from these and attempt to trace out the reflexes from an osteopathic point of view, we may find some more definite causes of these conditions and consequently some methods of treatment not found in standard text books might naturally suggest themselves.

Reflex symptoms that have been traced to eye strain by ophthalmologists are as follows:

Constipation, indigestion, heartburn, nausea, vomiting, nervous attacks, fear of impending calamity, irritability, despondency, insomnia, restless sleep, epilepsy, nervous twitchings and enuresis. All these symptoms have been seen to disappear after eye strain was corrected. There is no absolute way of proving that all these symptoms have existed because of eye strain. The existence and disappearance of some of them at the time of treatment for eye strain may be a coincidence. It is evident that eye strain in varying degrees may produce a train of symptoms similar to many above mentioned.

A patient, nervous, anxious, uneasy, and despondent, constipated, and having some indigestion, showed on examination contractures and tenderness at the third dorsal. It was found he was suffering from eye strain from overuse of glasses that were too strong for him. The eyes were refitted. He was wearing a

(R)+4.50 D. S. = +.50 cyl. Ax. 180. (L)+4.50 D. S. = +.50 cyl. Ax. 90 for close work and a (R)+2.00 D. S. = +.50 cyl. Ax. 180 (L)+2.50 D. S. = +.25 cyl. Ax. 90 for distance. The new glasses were—Reading— (R)+3.00 D. S. = +.25 cyl. Ax. 180 (L)+3.00 D. S. = +.25 cyl. Ax. 180 Distance: (R) + 1.50 D. S. = +.25 cyl. Ax. 180 (L) + 1.50 D. S. = +.25 cyl. Ax. 180

He was fitted two years previously. At that time the stronger glasses were correct. Eyes change more or less constantly, especially between the ages thirty-five to fifty-five years. When glasses are fitted, a weak ciliary muscle after a rest may become stronger and allow weaker glasses to be worn.

If a young person is fitted for myopia, in a few years he may discard his glasses as presbyopia develops. A person fitted correctly, who has a strong ciliary muscle may not be able for awhile to see as well with the glasses as without them. After they are worn awhile the ciliary muscle will cease its efforts to accommodate so much and the glasses give the desired effect. In some cases the doctor’s reputation to fit glasses properly may suffer at the hands of such people who sometimes refuse to take glasses, or after

getting them refuse to wear them.

In the case of the man just mentioned a refitting quieted the nervous symptoms—he became more cheerful and ceased to worry. Indigestion and constipation improved. The soreness and contractures were overcome in a few treatments.

Now let us ask the question, why is it that eye strain will cause nausea and vomiting? Also why will indigestion affect the eyes by causing “spools” in the vision?

A little osteopathic logic, based as it always is or should be, upon anatomy and physiology, may throw some light on this subject. No doubt every one of us has demonstrated many times clinically that indigestion from overeating will cause soreness and contractures at the third and fourth dorsal, the nerve center in the spine for the stomach.

The reflexes between the viscera and the eye are complex and difficult to follow. In giving the probable course of the nerve reflexes from the optic nerve to the third nerve Dr. Louisa Burns suggests the following: “The nerve elements of the retina start the impulse; it passes over that portion of the optic nerves which enter the anterior quadrigeminates, the cells of the quadrigeminates where the impulses are coordinated, then by axons of these cells to the lateral or viscero-motor nucleus of the third nerve, thence to the cells of the ciliary ganglion, and by the non-medulated (sympathetic) fibers of these, the short ciliary nerves to the non-striated muscles concerned, viz: the ciliary muscle, some fibers of the levator palpebral and the sphincter of the iris.”

The third nerve arises in the floor of the aqueduct of Sylvius from two nuclei; a lateral nucleus which is a viscero-motor group of nerve cells, and a central nucleus or a somato-motor group of cells. The somato-motor nucleus supplies all the extrinsic muscles of the eye except the external rectus and superior oblique which are supplied by the sixth and fourth respectively. The nasal branch of the ophthalmic division of the 5th sends fibers to the ciliary muscle. Association fibers connect the nuclei of the 3rd, 4th, 6th and 7th. The evidence is in favor of the 10th or pneumogastric having such association fibers.

We noted four places in the brain to which the optic tracts go before the radiations reached the center of sight in the occipital lobe. If we cannot follow all the reflexes through the brain and cord at least with the facts we have it is not difficult to imagine abnormal impulses coming over the third nerve from a straining of the ciliary nucleus, thence over viscero-motor fibers in the lateral horn of the cord, over the white ramicommunicantes, through the sympathetic ganglia, over the splanchnics to the stomach, producing abnormal peristalsis, nausea and vomiting. In turn we would have the somato-motor nerves to the muscles affected as before described, contraction and congestion of muscles of the spine.

When we have patients consult us and describe a train of symptoms like nausea, vomiting, nervousness, frontal and occipital headache, we should have eye strain in mind and inquire for lachrymation, photophobia, itching and burning lids and congestion of the eye. Any of these things should make us think of testing for ametropia in its various refractive errors, as well as a careful spinal and a nose and throat examination. General physical and laboratory diagnosis should not be neglected.

DISEASES OF THE EAR, NOSE AND THROAT

By J. DEASON

Diseases of the Ear

=Methods and Technic of Examination.=—The external ear may be examined by direct inspection with or without the aid of artificial light. The external auditory meatus may be examined by means of a simple conical ear speculum and reflected light from a head mirror. This method requires considerable practice but efficiency can and should be attained because it can be used under all conditions and therefore is a reliable method.

The Holmes electric auroscope which we use and recommend for examining the meatus and ear drum, is very efficient but like other electrical equipment is not always dependable. There are many electrical equipments for examining the ear, but so far I have found none other than the one above mentioned that is worth space in an instrument cabinet.

To examine the meatus, grasp the pinna and draw it firmly upward and backward. This tends to straighten the canal so that the aural speculum may be inserted well into the external canal. It must be remembered that the auditory canal is always sensitive and while there is really little danger of doing any harm by exercising ordinary care, the patient is always afraid of being hurt and one can accomplish better results by practicing careful technic.

If the electric auroscope is used, the eye should be placed very close to the lens and every part of the canal, walls and drum membrane carefully examined. The Holmes auroscope has a small tube and bulb, pressure upon which will vary the air pressure in the meatus and cause the drum to move. This must be done very carefully because in very thin, atrophic membranes there is some danger of rupturing the drum.

Diseases of the Auditory Meatus

=Inspissated Cerumen=, or hardened ear wax is one of the most common affections of the meatus. The cause in some cases can be traced to lesions of the mandible, but in many cases the cause is unknown.

=Treatment.=—Protect the clothing by means of a towel or rubber neck piece. By means of a soft rubber ear syringe, wash the canal thoroughly by forcing warm soap solution into it. I prefer concentrated liquid castile soap (any good soap will do) diluted about one to four in water as warm as the patient can bear it. The soap solution is contained in a pus bowl held tightly against the neck under the ear. There is little danger of using too much force with the soft rubber syringe.

In most cases the hardened cerumen will be dislodged by the syringing only. If this cannot be done, it may be well to discontinue the treatment until the following day. The solvent action of the soap solution will further reduce the hardened mass and it usually can be removed by syringing the following day. This method is preferable in many cases because patients dislike the pain which usually accompanies the use of a curet.

The dull loop curet is the most efficient and safest instrument for removing hardened cerumen that the syringe may fail to dislodge. This instrument must be used with great care because the membranes, long protected by the covering of cerumen are hypersensitive and bleed easily.

After removing the cerumen, the canal should be thoroughly dried and lubricated with some non-irritating lubricant. It is also well to place a small pledget of absorbent cotton into the external opening to protect the sensitive membranes from the cold, air and dust.

In drying the canal I prefer to use a small aluminum applicator, twisting a small piece of absorbent cotton on the end in such a way as to cover the tip well, thus making any injury from its use impossible.

Atrophic Meatus

Sensitive or itching ears as the patient commonly describes it, is a very common disease caused by any atrophic condition of the membranes of the auditory meati and frequently found in common with auditory or other cranial nerve deficiency or degeneration. The direct cause of the irritation is the collection of particles of dry cerumen.

=Treatment.=—The local treatment consists of syringing with warm (118° to 120°F) soap solution until all of the scaly cerumen has been removed. The canal is then dried and lubricated as described above. Several such treatments may be required after which I prefer the use of the continuous irrigating ear cup, using salt mixture instead of the soap. The same salt mixture as is recommended for nose and throat irrigation is satisfactory. After such irrigations the application of phenol-glycerine (10% phenol in glycerine) seems to be an efficient treatment.

The local treatment must, of course, be accompanied by corrective treatment to the mandible and upper cervicals.

Furunculosis

There are three acute affections of the ear which may usually be diagnosed from their points of tenderness or pain. Pain upon moving the lobe or pinna indicates furunculosis. Pain on pressure posterior to the angle of the jaw or externally in front of the ear indicates middle ear infection and pain on pressure over the mastoid region suggests mastoiditis.

Probably the most common of the painful diseases of the external meatus is furunculosis, which is a subcutaneous infection of the lining membrane of the meatus. The point of swelling may usually be seen but in some cases the entire canal is closed.

=Treatment.=—In all cases of occluded pus, drainage must be obtained, but in the early stages of furunculosis, it is not always possible to determine the place of “pointing” or the most desirable point to lance. As soon as the place of “pointing” can be located it is advisable to lance deeply by means of a curved paracentesis knife. The parts are thoroughly cleansed and anesthetized by applying phenol and neutralizing with alcohol. The external parts are first painted with alcohol to prevent “burning” from any phenol which may be dropped upon them. A small cotton applicator is used, applying the concentrated solution of phenol or the crystals (using only a small amount of phenol) to the affected parts and immediately neutralizing with alcohol. Care must be observed not to apply any phenol to the drum membrane and the operator must be sure that the action of the carbolic acid is completely neutralized by a liberal application of alcohol.

The knife blade is placed beyond the furuncle, its curved point turned outward and quickly drawn forward through the furuncle, cutting deeply. The canal is then packed with a pledget of cotton dipped into phenol-glycerine.

If the place of pointing cannot be seen, palliative treatment may be applied by thoroughly cleaning the meatus, drying and applying a phenol-glycerine pack. Heat may be applied by means of a therapeutic lamp. Any electric light bulb or the dry electric pack will do. The external parts are well lubricated with paraffin oil and the heat applied continuously or intermittently until the pain is relieved.

Infection of the Meatus

Infections of the meatus are frequently secondary to, or accompanied by furunculosis. The treatment, therefore, is similar to that of furunculosis.

Always try to locate the point of infection, lance or curet, apply phenol or other chemical germicide, neutralize, dry and pack with phenol-glycerine. After the point of infection has been thoroughly drained, cleanliness and protection from dust or further infection is all that is necessary.

In all cases of infection of the external meatus, suspect middle ear abscess as a cause. There may be a pin-point opening through the drum, from which the infection has originated and is being maintained.

=Otomycosis= or fungus infection of the auditory meatus is rare. It usually resembles other infections symptomatically, but often without pus. A microscopic examination will serve to diagnose the condition.

The treatment consists of thorough cleansing, drying and the free application of alcohol. Alcohol is dropped into the ear until the canal is full and a pledget of cotton applied to retain it. Usually two or three applications are sufficient to effect a cure.

=Eczema= of the auricle and meatus is of two types, the squamous or scaly form and the sclerotic form. Both forms are chronic and may be readily diagnosed by the appearance.

=Treatment.=—Some cases are very difficult to cure but we have had excellent results with the following treatment: Careful adjustment of cervical and mandibular lesions; thorough treatment of any local infections of head or neck; direct application of phenol-glycerine, local cleanliness and protection from irritation.

Diseases of the Middle Ear

Clinically the middle ear consists of the tympanic cavity and its contents, the Eustachian tube and the mastoid cells.

Acute Suppurative Otitis Media

Acute infections of the middle ear result from acute nasopharyngeal affections such as colds, influenza, measles, mumps, whooping cough, etc. Bathing in contaminated water often results in infection to the middle ear through the Eustachian tube.

=Diagnosis.=—Earache, pain on pressure under the angle of the jaw and sudden deafness are the symptoms. (There are also the common febrile symptoms.) The chief physical signs are: redness and bulging of drum membrane, and contraction and tenderness of upper cervical muscles.

=Treatment.=—If the patient is seen before the drum has ruptured it is seldom necessary to lance the drum if the proper treatment is given promptly.

Drainage must be obtained and maintained by catheter aspiration through the tube irrigation of the nasopharyngeal cavity, irrigation of the meatus by means of the continuous ear irrigator and application of dry heat over the affected part. Heat is best applied by means of a therapeutic lamp. (Any lamp with reflector that will furnish proper heat is efficient as there is no virtue in colored light.) The skin surface over the ear, side of face and mastoid region is first well lubricated with some mineral oil to prevent blistering and the heat is applied either constantly or intermittently. A pledget of absorbent cotton dipped into phenol-glycerine is placed in the meatus and forced loosely against the drum. This should be removed every few hours and a fresh pledget put in.

The neck and upper dorsal muscles should be kept relaxed and adjustive treatment given frequently.

Under this treatment the pain should be relieved and the bulging of the drum should disappear in from two to twelve hours. If this is not accomplished or if the condition grows worse, the drum should be lanced. See some text on otology for technique. In my experience, very few cases have required paracentesis.

It must be remembered that treatment should be continued regularly and for some time after the pain and other symptoms have been relieved or a recurrence is probable. Patients should have daily treatment until the physician is sure that no complication or recurrence is likely to result.

If the patient is not seen until after the drum has ruptured, the same treatment may be applied except the irrigation or syringing of the meatus. This, in case of ruptured drum, may force pus into the mastoid cells resulting in mastoiditis. Instead of syringing, the auditory meatus is cleaned by means of a cotton applicator or by aspirating with a catheter. At all times drainage through the meatus must be maintained until the drum begins to heal.

Acute Mastoiditis

Acute mastoiditis results from acute or chronic otitis media. In some cases the otitis media may have been only a mild attack.

=Diagnosis.=—There is no one symptom that is positively diagnostic but a number of signs and symptoms must be considered as follows:

1. Always suspect mastoid complications in acute otitis media and watch for this complication daily. Most cases have some mastoid inflammation.

2. Pain or swelling over mastoid. Pain may not be present, but usually is, sometimes radiating over temples and eye on affected side.

3. Tenderness on pressure not always present. May be very marked. Tenderness extending to tip or above ear means extension of infection. If persistent tenderness over tips with marked swelling and discoloration—operation is indicated.

4. Swelling, not always present, but sometimes very marked. If extreme swelling and bluish discoloration—usually means operation.

5. Temperature varies from normal to 104° or 105° F. Temperature of more than one or two degrees means systemic absorption and suggests surgical drainage. Streptococcus or staphylococcus infections cause higher temperatures and require drainage

earlier than other infections.

6. Transillumination not positive, but of some value. Like X-ray, usually shows dark, because of inflammation, but must rely upon symptoms, as above.

7. =Microscopic.=—Stain for pus, bacteria and bone debris. Hematoxylin stain shows dark bone particles if there is bone disintegration.

8. =Blood Count.=—If absorption, there will be some variation in proportions of leucocytes. Any high leucocytosis shows systemic absorption and the natural attempt to overcome the infection.

=Non-Surgical Treatment.=—1. Drainage must be maintained from middle ear through tube or drum or both. Catheter aspiration through tube. Sometimes gentle inflation to clear the tube, followed by aspiration is effective.

2. If drum is ruptured, aspirate middle ear by catheter or by Moore's method or both. =This is very important.= If no aspirating machine, use syringe and pump meatus and tube persistently. Dry meatus and keep well open.

3. Patient should be kept in bed if symptoms are marked, with light diet and bowels well open.

4. =Heat.=—Apply oil or other lubricant over whole side of face and head and apply heat by means of "therapeutic" lamp intermittently. Thirty minutes light on and fifteen minutes light off. The light-heat (any electric lamp with reflecting shade will do) is much better than hot water bottle or electric pad or sand bag. The heat must be kept going day and night if symptoms are marked until the pain has entirely subsided. Heat is most efficient in the early stages. After symptoms are well marked, the ice pack is more desirable.

5. If drum is not ruptured, heat may be applied by means of Deason's continuous irrigating cup. Start at 116° F. and gradually increase to 123° F. if patient can bear it.

=Surgical.=—If drum has not ruptured and symptoms continue, it is best to make free incision of drum,—keep open and apply (2) above.

=Indications for Mastoid Operation.=—There are no definite signs, symptoms or tests that will determine positively when operation should be done. If the above non-surgical methods are practiced, few cases will require operation, but many will develop into chronic mastoiditis and so it is very difficult to decide whether a mastoid operation should or should not be done. It is best to explain thoroughly the possible complications to the patient and relatives and request them to assume responsibility. Mastoid operations are attended by very little danger when properly done.

=Signs and Symptoms Suggesting Operation.=—Acute otitis media with mastoiditis.

(1) Persistent pain and swelling not relieved by non-surgical treatment.

(2) Marked protruding of posterior wall or meatus.

(3) Marked tenderness, swelling and discoloration above ear or over tip of mastoid.

These with temperature of more than 102° usually are enough to demand immediate drainage.

(4) Any evidence of extension of pus under skin of neck below tip. A positive indication for drainage.

(5) Any indications of brain or meningeal involvement such as very marked and persistent headache, partial or total loss of consciousness, etc.

(6) Indications of labyrinthine involvement such as marked vertigo, etc.

(7) Sudden cessation of discharge means obstructed drainage from middle ear or from mastoid into middle ear and if drainage cannot be restored by aspiration, this means operation.

(8) The whole clinical picture must be carefully considered at all times. Take no chances. Advise operation before someone else finds it too late.

Chronic Mastoiditis

=Cause.=—Always from unsuccessfully treated acute form or from chronic suppurative otitis media.

=Non-surgical treatment.=—See chronic suppurative otitis media. We have had a few cases that were seemingly permanently cured by non-surgical treatment, but believe they are rare.

=Indications for Operation.=—1. Recurrent exacerbation of acute or chronic otitis media.

2. Constant discharge which resists treatment for chronic suppurative otitis media.

3. Continued pain or recurrent pain and swelling following acute otitis media.

4. Open sinus into mastoid either external or through meatus.

5. Cholesteatoma.

6. Symptoms of labyrinthine or brain involvement following acute otitis media.

7. Definite evidence of bone disintegration in mastoid.

As stated above, none of these are definite indications. The whole group of signs and symptoms are to be considered.

Chronic Suppurative Otitis Media

=Etiology.=—Chronic suppurative otitis media usually results from an unsuccessfully treated acute otitis media. If in acute otitis media there has been bone erosion or extensive destruction of the mucous membrane by a virulent infection, chronic suppuration is likely to result. A persistent mastoid infection following otitis media is likely to result in chronic otitis media and this is strong argument for early mastoid operation.

1. Otitis media resulting from some virulent infection such as the recent influenza pandemic or scarlet fever is always more likely to result in mastoiditis and chronic suppuration of the middle ear.

2. Such infectious agents as streptococcus, staphylococcus, long-chain pneumococcus or bacillus influenzæ are likely to result in chronic suppurations.

3. Lowered vitality from any cause.

4. Inefficient drainage from failure to aspirate the Eustachian tube, delayed perforation or failure to lance drum sufficiently early.

5. Mastoid necrosis, which maintains drainage into the tympanic cavity.

6. Abnormal granulations, polypi, etc. in tympanic cavity.

7. Chronic inflammation with suppuration of the epipharynx or Eustachian tubes.

8. Cholesteatoma resulting from perforated drum and growths of epithelium extending into the middle ear cavity.

=Diagnosis.=—The diagnosis is easy because nearly every case of discharging ear without pain is chronic suppurative otitis media. The determination of the exact nature of the condition present is not only very important but very difficult.

Differential diagnosis consists in determining the nature of the infecting organism and the nature and extent of the pathology.

1. Direct examination of the external meatus after drying with cotton applicator usually determines the location and extent of perforation of the drum and the general nature of the discharge, whether purulent or mucopurulent. Very rarely one finds a serious discharge which means a very slight infection or discharge from non-infective inflammation. The presence of whitish or greyish pus, mucoid and stringy, usually means pneumococcus infection. Greyish, purulent non-mucoid discharge usually indicates streptococcus or bacillus influenzæ infection. Yellow, purulent discharge suggests staphylococcus infection. The general appearance of the discharge, however, cannot be considered of important diagnostic value because most chronic suppurations are mixed infections, because of long exposure to external contamination.

2. After cleaning the meatus, several smears should be made directly from the opening in the drum. By staining with methylin blue or gentian violet, the nature of the bacterial infection can be determined and this is very important.

By staining another smear with hematoxylin and washing in water, any dark irregular particles, bone debris, may be found, which means bone disintegration. This too, is very important.

3. Transillumination is sometimes of value. The mastoid may be transilluminated by placing a good rubber covered transilluminating lamp over the mastoid and observing the external meatus through an aural speculum. If the mastoid is free from infection the light will pass through and illuminate the meatus.

4. The X-ray plate is, of course, the best means of determining the nature and extent of mastoid involvement.

=Treatment.=—This is certainly one of the most difficult diseases of the ear that one is ever called upon to treat and the physician should be cautioned against offering a favorable prognosis. Perhaps the most difficult thing about its treatment that the doctor has to learn is that practically none of the so-called antiseptic washes do any good, but on the other hand they often do harm. Certain general principles are important and the treatment must depend upon the nature and extent of the infection and pathology present in each case.

The constitutional treatment consists of everything that will increase the patient's general resistance and certainly all lesions of the cervical, upper dorsal and mandibles must be properly adjusted, but this is not enough. All spinal lesions that may exert an influence on metabolism and elimination are of important consideration. The diet, habits and environment of the patient must be considered.

A careful examination of the nasopharyngeal tract may reveal some other focal infection, such as chronic tonsillitis, pharyngitis or sinuitis, which is maintaining the infection through the Eustachian tube. There may be a focal or general infection of some other part of the body, which is reducing resistance or causing a hematogenous infection of the tympanic cavity or mastoid cells.

Drainage must be maintained in all cases, both through the Eustachian tube by catheter aspiration and through the drum by aspirating and drying. If the perforation in the drum is small or in the middle or upper part, it should be opened down to the floor so that the contents may be more easily removed and better drainage established. It is well first to thoroughly cleanse the meatus and tympanic cavity by syringing with salt mixture (salt 3 parts, borax 2 parts and soda 1 part, a teaspoonful to a half pus bowl of water) at from 116° to 118° F. After syringing, the meatus is carefully dried, and the middle ear cavity aspirated through the tube and drum opening. The advantage of this simple treatment is thorough cleanliness and drainage with the minimum of irritation. This treatment given daily or thrice weekly will often cure the case.

Staphylococcus and streptococcus infections usually respond to the following treatment: After thoroughly cleansing as above, the meatus and tympanic cavity is syringed with a one to four or one to five dilution of Dakin-Carrel solution (Hyclorite may be used instead) followed by aspiration, the fluid being drawn through the tube, thus preventing reinfection from that source.

Pneumococcus infections do not respond to either of these methods of treatment. The pneumococcus, because of its capsule, is not affected by antiseptics, but on the other hand the irritation of the tissues caused by their use, only gives the infective agent a better opportunity for growth.

In pneumococcus infections we have found the following method efficient: Thoroughly cleanse the meatus and middle ear cavity by salt mixture syringing, aspiration and drying. The meatus and tympanic cavity is then filled with a neutral mineral oil. The oil is also pumped through the Eustachian tube. It is the purpose to fill the entire cavity and its openings so thoroughly that no air can enter. In some cases we have used bismuth paste after the oiling with excellent results. The pneumococcus is aerobic and if all air can be kept away for a considerable time, it furnishes an unfavorable culture environment with little irritation to the membranes.

=Surgical treatment.=—The presence of bone debris indicates bone disintegration in the tympanic cavity or mastoid cells. If the mastoid cells are thus involved there is little chance for direct treatment. If such cases do not respond in a short time to any of the above methods of local treatment, ossiculectomy or mastoid operation may be necessary. Some specialist surgeons claim from 80% to 90% favorable results from mastoid operation in such cases.

Non-Suppurative Otitis Media—Catarrhal Deafness

Deafness is any impairment of normal hearing and is that symptom next to pain and chronic discharge that causes the patient to visit the doctor. If acute diseases of the ear, nose and throat could always be successfully treated, there would be little trouble from the symptoms of chronic pathology. It must be understood that catarrhal deafness is a symptom of chronic otitis media and is, therefore, seldom of recent origin.

=Etiology.=—Chronic otitis media is nearly always the result of the extension of infection through the Eustachian tube and has come from some acute or chronic nasopharyngeal infection. Chronic colds, pharyngitis, tonsillitis, sinuitis, etc., resulting in acute or chronic otitis media either with or without suppuration, constitutes the beginning of catarrhal deafness.

=Symptoms.=—There is seldom any pain with this disease. Some cases have an occasional acute attack with pain and other symptoms of acute otitis media.

Deafness, varying with the progress of the pathologic changes, is always present. The patient in the early stages will seldom admit that he suffers from deafness and often he is honest because he may not realize that he cannot hear normally until his otitis media has progressed to the second or third stage. Most patients, in fact, do not become alarmed about their hearing until it is too late to restore normal hearing. For this reason, physicians should be on the lookout for such conditions and should advise special treatment early.

The human species in its present environment, depends much less upon the organs of special sensation than do the animals of the wild, and they may therefore be very deficient in sight, hearing, smell, etc. without actually realizing this loss.

In addition to deafness there are other symptoms such as occasional or constant fullness or feeling of “stuffiness” as the patients express it, due to partial or complete occlusion of the Eustachian tubes. Tinnitus aurium or head noises is very common and often the most annoying symptom. Autophony, or the loud sound of the patient’s voice to himself, which often causes him to speak low and indistinctly, occurs in the later stages. Presbyacusia, or the inability to adjust the hearing apparatus to variations in pitch, commonly occurs in the second stage and is evidenced by the fact that the patient does not hear when more than one person is talking. Paracousis or perverted phenomena of hearing, such as the better hearing of some persons in a noisy environment, is a symptom of the third stage of otitis media and often means an unfavorable prognosis, so far as marked improvement in hearing is concerned.

=Pathologic Stages.=—For convenience of discussion we may consider chronic otitis media in three stages.

=The First Stage.=—The active pathology is limited to the pharyngeal portion of the Eustachian tube with some inflammation of the membranes of the tympanic cavity. Closure of the tube followed by absorption of the oxygen causes a decreased pressure in the tympanic cavity and thus a retraction of the drum, decreased movement of the ossicles and a general decrease in function of all tympanic structures. Deafness in this stage may be very marked, especially if the Eustachian occlusion has occurred from some nasopharyngeal acute inflammation. There may be pain but there is always a characteristic “fullness” and sometimes dizziness. Deafness in these cases varies with weather changes. If proper treatment is had in time, the progress of the pathology can be stopped and every case can be restored to normal hearing.

=The Second Stage.=—The active pathology has extended throughout the Eustachian tube causing marked occlusion and some stenosis. There is further inflammation of the tympanic structures with an increase in the symptoms of the first stage. The drum membrane is less movable but there is no fixation of the ossicles. Pressure upon the bulb of the auroscope causes movement of that part of the drum to which the malleus is attached. The drum is thicker, more retracted, and less movable than in the first stage. Presbyacusia is common and often marked, but there is no paracousis. More than 90% of these cases can be materially improved and many can be made to hear normally if proper treatment is given in due time.

=The Third Stage.=—The active pathology in the third stage consists of an involvement of the entire mucous membrane lining the Eustachian tube and tympanic cavity. These membranes are all chronically hypertrophied. The Eustachian tube, however, is sometimes fairly well open, but the ossicular attachments are more or less fixed by hypertrophied tissue and adhesions and the drum is markedly retracted, thickened and usually very immovable. The deafness is usually quite marked, head noises are commonly present and often very annoying. Patients usually do not notice a variation in their hearing from weather changes. Presbyacusia is present in 80% of cases and their hearing for low tones is much reduced.

Unless there is a complicating nerve affection these cases hear well by telephone, which means that they can also use an electric hearing instrument to advantage. These cases can never be restored to normal hearing, but many of them (30% of my cases) can have some improvement and in most cases I believe the progress of the pathology can be stopped, and this is always well worth while because their hearing is likely to be entirely lost if something is not done.

=Psychologic Stages.=—There are three rather distinct psychologic stages in catarrhal deafness. The first, the period in which most patients refuse absolutely to admit that they are deaf even to the aurist upon whom they call for treatment. They insist that

they hear perfectly if people would only speak distinctly. This is partially true, because up to the third stage of deafness the voice can be fairly well heard if people would only articulate clearly. In the second stage patients admit that they don't hear well, but insist that they are going to recover normal hearing and often resort to various kinds of injurious treatment. In the third stage they give up all hope of ever regaining their hearing, become morose, and avoid company. These psychic stages do not always correspond with the pathologic stages given above.

=Diagnosis.=—The external auditory meatus, drum membrane and ossicular chain, constitute the apparatus whose function is that of conduction of sound waves to the perception apparatus of the inner ear. The function of the conduction apparatus varies inversely with the progress of pathologic change in these structures. The perception apparatus, the structures of the inner ear, are not necessarily affected by middle ear pathology, but on the other hand, sounds transmitted by bone conduction not only seem louder but they last longer because the "escape of the excess" of sound thus transmitted is hindered by deficient conductive mechanism. This explains why such persons hear well by telephone and why the tuning fork, whose base is held to the mastoid (provided there is no nerve affection) may be heard for a greater time than normal. Likewise the prong of the vibrating tuning fork when held near the concha is heard for a shorter time than normal, because of the deficient function of the conduction mechanism.

Tuning forks are known by their number of vibrations per second, such as 16, 32, 64, 128, etc. Three or more forks are required to make an accurate measurement of the conduction and perception functions—a low fork about a 32, for the low tones, 128 or a 512 for the medium tones and a 2048 for the high tones.

A good set of forks should be selected and standardized, i. e., the normal bone and air conduction of each fork determined by testing it on a number of persons whose hearing is known to be normal. For the general practitioner who cares only to get a general idea of the extent of the pathology, one fork of medium pitch such as a 128 or 512 will be sufficient.

To measure the function of hearing, the fork is set into maximum vibration, its base held against the mastoid and the patient is asked to state when he no longer hears it. This length of time in seconds is recorded as "bone conduction." The fork is then held near the concha and the patient again states when he does not hear it. This length of time in seconds is recorded as air conduction.

Normal Hearing

=Tuning Fork Test.=—The normal time rate in seconds set of forks is as follows:

Fork 32 64 128 512 2048 4096 B. C. 25 30 30 20 10 A. C. tone 70 90 90 40 20

The tuning fork test, carefully made, is the only known method of measuring the functions of the various structures concerned in audition.

=The Whisper Test= is made by producing a clear whisper from residual air only, which should be heard about twenty feet by a normal ear.

=The Watch Test= is made by using some loud ticking watch (I prefer an Ingersoll), holding it first near the ear until the patient recognizes the tone, and then taking it beyond the hearing distance and approaching the ear until it is heard. I prefer also to move away from the ear until the limit is reached and strike an average of this with the above results. The average eighteen size Ingersoll watch can be heard for from 100 to 150 inches by the normal ear.

The practical test for the patient is his hearing from the spoken voice, and is the most reliable so far as permanent results are concerned.

=Low Tone Limit.=—The lowest limit of hearing is about sixteen double vibrations per second, but the lowest practical limit is about thirty-two. There are few people with normal hearing and with musically trained ears who can recognize a definite tone lower than this, so I consider the thirty-two fork sufficiently low for all practical tests.

=Conduction Deafness.=—Low tones are lost in tympanic involvement or conduction deafness, and are diagnostic in such cases, but are of no particular value in nerve deafness except when that is complicated by catarrhal deafness.

=Practical Hearing Limits.=—The human voice varies from about 60 to 150 double vibrations per second, and most sounds that we really need to hear are less than 700 vibrations per second. This is the reason for using the low forks, 64, 128 and 512.

=Measurement of Nerve Force.=—To measure auditory nerve force, the fork (say the 128, whose normal B. C. is 30 seconds) is set into vibration and held gently and with even pressure against the mastoid and the patient is asked to tell or signal the doctor when he ceases to hear the tone. Two or more tests may be made to determine the patient's personal equation, but the use of control forks (the 64 and 512) will show any such error. Granting that there is no complicating pathology, tympanic or labyrinthine, the number of seconds of hearing over 30 will be the patient's auditory nerve force. For example, if he hears the fork 30 seconds his hearing will be thirty-thirtieths or normal. If his hearing is 25, 20, 15 or 10 seconds, his auditory nerve force will be respectively 25-30, 20-30, 15-30 or 10-30.

By means of this method an accurate measurement of the functions of hearing can be made and a definite prognosis can be given. I never use any of the various named qualitative fork tests for hearing, because they have no value to one who employs this system.

FOOT NOTE—In the chart T is used, meaning that tone is heard, while S indicates sound but no tone.

FOOT NOTE—It is not the purpose to give any detailed or differential methods of diagnosis because if one cares to treat these diseases he will of course, study a special text on this subject. The methods here given are only for the general practician who wishes a general idea of the condition present.

Summary of Diagnosis of Different Stages of Catarrhal Deafness

=First Stage.= 1. Fork 32 128 2048 B. C. 35 20 A. C. T 70 40

2. The drum is only slightly retracted but freely movable.

3. Whisper heard from five to twenty feet.

4. Ingersoll watch heard from 30 to 150 inches.

=Second Stage.= 1. Fork 32 128 2048 B. C. 40 20 A. C. T 60 40

Note that the tone of the 32 fork is heard, the 128 fork has increased in bone conduction and reduced in air conduction but that the bone-air ratio is direct, that is the patient hears longer by air than by bone conduction. Note also that the high fork is still normal.

2. The drum will be found retracted but that part to which the malleus is attached is still movable when tested with the auroscope.

3. The whisper is heard from two to ten feet.

4. The Ingersoll watch is heard from six to sixty inches.

5. Presbyacusia but not paracousia is present.

=Third Stage.= 1. Fork 32 128 2048 B. C. 45 15 A. C. S 20 30

The typical diagnostic points in third stage catarrhal deafness are: 1. Tone for the 32 fork is lost. 2. There is an inverted bone-air ratio for the medium fork. The drum is retracted and the malleus fixed. 4. The whisper may be heard at less than one foot or not at all. 5. The Ingersoll watch is heard less than six inches from the mastoid. 6. Paracousis Willisiani is present.

For the general practician this is important because he can make a rather definite prognosis.

=Treatment.=—The treatment will be given briefly because space would not permit of lengthy discussions of details of methods and technic.

FOOT NOTE—Note that the patient hears the tone of the low fork, that the 128 fork has its bone conduction slightly increased (30 to 35) that the air conduction is slightly decreased (90 to 70) and that the high fork remains normal.

A careful examination should be made for some source of focal infection about the nasopharyngeal tract. Chronic or subacute tonsillitis,

pharyngitis or sinuitis or root abscess are often a cause, and not much will be accomplished in improving the otitis media until these focal infections are found and properly treated. The original cause of these focal infections may have been some bony lesion, but to successfully correct such lesion now does not mean that the source of infection will be removed.

Auto-intoxication from gastro-intestinal disease is common. In my cases, 80% of the third stage have chronic constipation or other chronic gastro-intestinal affection.

In many severe acute affections of the nasopharynx the inflammatory process has left the Eustachian tube occluded or stenosed and the pharyngeal fossa filled with adhesive bands. It is not uncommon to find the epipharynx and pharyngeal fossa filled with partially atrophied adenoid tissue or if the curet method has been used for removing adenoids, there is often connective tissue adhesions and any or all of these may prevent the normal ventilation of the tympanic cavity by way of the Eustachian tube.

In such cases surgical removal of these obstructions and dilation of the tube is necessary. My practice has been to give a general anesthetic (nitrous oxide or somnoform will be sufficient in many cases) and by means of an adenotome (La Force or Cradle, I never use a curet) remove all adenoid tissue. Then by means of the finger I carefully remove any adenoid tissue in the posterior nares and pharyngeal fossæ that the adenotome may have failed to get and also dilate the pharyngeal portion of the tube by inserting the finger.

This operation if carefully and thoroughly done and if preceded and followed by the proper surgical cleanliness and supportive treatment, will when indicated, accomplish excellent results. The after treatment is even more important because if this is not well done, no results or even unfavorable results may occur. The after treatment consists of daily irrigations of the nasopharynx, thorough attention to upper thoracic, cervical and mandibular lesions, aspiration of the Eustachian tubes and other local treatment to the nasopharyngeal membranes. After the operation has been done it is best to do no digital manipulation of the pharynx for from three to six days. After this time digital treatment, gentle dilation of the Eustachian orifice to maintain its patency, stretching of the soft palate to reestablish proper nerve function and the application of deep pressure in the pharyngeal fossæ to stimulate the otic ganglion is important. This treatment is not massage in any sense but definite, purposeful, manipulation and if carefully done will be followed by excellent results.

Since the origin of this method of treatment, there has been much comment on its value and many have tried or at least they thought they tried it with unfavorable results. The causes of failure are, attempting treatment in cases impossible of cure, or poor diagnosis, improper technic of operator or incomplete operative procedure and inefficient supportive treatment.

It must be understood that not all cases of otitis media even in the beginning stages require the above method of treatment or will be benefited by it. Those cases which have resulted from other causes than acute pharyngitis seldom require such radical methods of treatment.

In every case, the cause must be found and consistent treatment given. In my experience, the radical method of treatment has not been found necessary in more than twenty per cent of cases of chronic otitis media. In the other cases the treatment consists of removing sources of focal infection (about forty per cent) and normalizing nasopharyngeal reflexes by osteopathic and local treatment (about forty per cent). In all cases, the treatment must be complete. To remove thoroughly all obstruction from the epipharynx and leave a source of focal infection in the tonsils will accomplish little, or to remove carefully all pharyngeal obstruction and all sources of focal infection will not restore normal functions of the middle ear structures if the osteopathic lesions and gastro-intestinal perversions are neglected. Surgery in itself, even though carefully and thoroughly done, is not efficient treatment and this is why the medical specialists fail in this disease. After the necessary surgery has been done, then normal tone must be restored to the various tissues involved. Normal reflex mechanisms must be reestablished and this can be done by thorough and efficient osteopathic corrective work and the proper local treatment directly to the structures affected.

Meniere’s Symptom Complex

This is a form of catarrhal deafness with all the characteristic pathology of the first or second stage, but in which, due probably to sudden tubal occlusion, there results a marked variation in the intralabyrinthine pressure and there are, therefore, the symptoms of conduction deafness combined with labyrinthine involvement somewhat resembling Meniere’s disease. There is dizziness or even vertigo, with head noises, but not the marked prostration and nausea which characterizes Meniere’s disease.

=Treatment.=—The treatment is the same as in the first stages of catarrhal deafness and the prognosis is always good. The labyrinthine symptoms are usually completely relieved as soon as the middle ear is ventilated.

Diseases of the Inner Ear

=Acute Suppurations.=—Acute suppurative diseases of the labyrinth occasionally result from the extension of infection from the tympanum but they are certainly very rare. Such conditions may result from acute suppurative otitis media in which there has been an excessive collection of pus without rupture of the drum or drainage through the tube but this very rarely occurs and after drainage has been established, labyrinthine infection is hardly possible.

=Diagnosis.=—Labyrinthitis is of several forms but in general, there are the symptoms of labyrinthine involvement such as: nystagmus, vertigo, nausea, vomiting, headache, earache, deafness and febrile symptoms. When labyrinthitis is suspected, an aurist of much experience should be called into consultation at once.

=Treatment.=—Suppurative labyrinthitis is not in itself a fatal disease but dangerous complications may result because of the close proximity to so many delicate structures. Threatened meningeal infection requires surgical drainage, but unless meningeal infection is imminent, surgery is contraindicated. Since the mortality, considering dangers of complications, is not high (about 10%) and since such operations are very complicated and require great surgical skill, we may conclude that surgery is generally contraindicated.

Non-surgical treatment consists of keeping the patient quiet in bed, liquid diet, and good elimination. Drainage through the middle ear or Eustachian tube must be maintained.

Deep manipulation of the cervical structures will help to maintain lymphatic drainage but any treatment which necessitates much movement of the head should be avoided until the symptoms of vestibular irritation have ceased.

Non-Suppurative Labyrinthine Diseases

=Meniere's Disease.=—This disease is caused by hemorrhage into the labyrinth with the following symptoms: There is sudden and intense vestibular irritation such as vertigo, marked tinnitus, nausea, vomiting and complete deafness on the affected side. There may also be cerebral disturbances and loss of consciousness.

=The Prognosis= depends upon the extent and severity of the pathology. It is probable that those cases in which recovery occurs quickly are not true cases of Meniere's disease but have some causes other than labyrinthine hemorrhage. Such cases are perhaps Meniere's Symptom Complex.

=The Treatment= consists of complete rest in bed, light diet, and good elimination until the marked irritation has passed. It has been my practice to carry out further treatment similar to that of the treatment of nerve deafness to be given later. Many of these cases will make complete recovery.

Nerve Deafness

The term "nerve deafness" is generally used very carelessly to apply to any chronic or non-suppurative process of the labyrinthine structures other than those mentioned above, which cause impaired hearing.

Nerve deafness is not an uncommon disease. In my cases of deafness there has been some involvement of the labyrinthine structures or auditory nerve in 27% of the cases examined. I think the reason for most authors putting the percentage of nerve deafness much lower than this is because of inexact methods of diagnosis. The above percentage is based upon the actual measurement of nerve force. See measurement of nerve force under non-suppurative otitis media above.

A careful study of cases by the method of actual measurement of nerve force, shows that there are two distinct forms of nerve deafness. In one there is only a deficient function of the structures of the labyrinth, due perhaps to some perverted physiologic function, and this form we may call auditory nerve deficiency. The other form of nerve deafness, due probably to an actual degeneration of the nerve or its end organs in the labyrinth, may be properly known as auditory nerve degeneration.

=Auditory Nerve Deficiency.=—A study of our case reports shows that in 64% of the cases in which the nerve force was 16-30 or higher (more than half) favorable results were obtained, provided that there was no complicating labyrinthine affection. These cases have been classed as "nerve deficiency" and the pathology as functional. A favorable prognosis (64%) may be offered.

Example of tuning fork findings: Fork 32 64 128 512 2048 4096 B. C. 18 20 20 20 10 A. C. T 50 60 60 40 20

In addition to the tuning fork findings the voice and watch test will be reduced to from one-tenth to two-thirds normal. The patient often complains of itching meati and dry nares. There are usually no signs or symptoms of labyrinthine affection.

=Treatment.=—The treatment consists of local treatment to the nasopharynx, tubes and meati as described under the treatment of chronic otitis media. Everything should be done to build up the patient's general health and improve the local nutrition. It is highly essential to search the entire system for sources of focal and general infection. Auto-intoxication from chronic gastro-intestinal disease was found in 90% of our cases. Any treatment therefore that will restore normal gastro-intestinal function is indicated. Recently we have had some excellent results from colonic irrigation and the proper adjustment of diet in such cases. Any source of focal infection must of course receive proper attention.

The osteopathic corrective treatment consists largely of careful attention to lesions of the splanchnic area because of the importance of normal digestion, metabolism and elimination. This is certainly a most important part of the treatment and should never be neglected. Upper cervical and mandibular lesions have much to do with the local nutrition to the ear structures and these must not be neglected. The fact that we almost constantly find evidence of deficient nutrition to the meati and drums in this disease together with lesions of the mandible, suggests a local osteopathic cause.

=Auditory Nerve Degeneration.=—In those cases in which there is a measurable deficiency of nerve function of less than half the normal we have found that very few respond to treatment. (See table above.) The cause has therefore been attributed to a structural pathology and the condition called auditory degeneration.

Example Table:

Fork 32 64 128 512 2048 4096 B. C. 10 12 8 5 2 A. C. S 20 25 15 7 5

There is usually very marked impairment of hearing for voice and all other sounds. The Ingersoll watch may be heard five or ten inches, but usually not at all, and the whispered voice heard only a few inches or not at all. There are nearly always signs and symptoms of labyrinthine deafness and evidence of tone islands. The deafness in these cases is usually progressive regardless of any treatment.

In this disease there is nearly always an associated affection of the labyrinth as shown by the high forks. The fractions represented by the high forks will agree in proportion provided there is no labyrinthine involvement.

Our results in auditory nerve degeneration have been measurable improvement in only 2% of the cases treated. The prognosis is therefore very poor and I believe we should always tell our patients frankly that there is almost no chance for improving their hearing in such cases. The treatment is the same as that given for nerve deficiency and because of the general good that may be had from treatment, that is, the improvement of the general resistance, it is often well for the patient to have such treatment to stop the progress of further special sensory degeneration.

It should always be our purpose to treat the patient rather than to treat some particular organ only and if this method is followed, our general results will surely be much higher.

Diseases of the Nose

=Method of Examination.=—For use in nasal examinations and treatment, a suitable chair with adjustable headrest is of much value because if the patient is not comfortable and in a convenient position, the work is very difficult. A few instruments, such as the following, are very essential: A sterilizer for instruments, head mirror and reflecting lamp, nasal speculum, tongue depressor, tonsil pillar-retractor, a nasal packing forceps and a few aluminum cotton applicators. These instruments are few and comparatively inexpensive, but are of more practical value than a lifetime collection of electrical apparatus. Any physician can readily learn the use of these instruments and the methods of examination by attending the clinical sessions of our conventions. Methods and technic of treatment, however, require much practice and experience to develop efficiency.

Acute Rhinitis

This disease, commonly known as a "cold in the head" is one of the most common, and because of the complications which so commonly result, a disease which really requires careful consideration.

=Etiology.=—The predisposing cause is reduced resistance and individual susceptibility to air-borne irritants and infective organisms.

Direct exposure of some insufficiently protected part of the body such as the feet in cold, damp weather, exposure of some unprotected part of the body to draughts or exposure of the whole body to slightly reduced temperature for a considerable time, are the common causes. In cold weather, it is very important that the proper indoor humidity be maintained, because the drying of the mucous membranes renders them susceptible to infection. This disease is not only contagious at times but may even become endemic from some specific and virulent organism.

The complications which may and often do follow such infections are laryngitis, bronchitis, pneumonia, etc. and any one or more of the focal infections, such as sinuitis, tonsillitis, or middle ear infection. A focal infection thus caused may become chronic and render the patient constantly susceptible to head colds. In fact in those persons who suffer from chronic head colds, there may nearly always be found some focal infection, such as the above named, and it is often impossible to get permanent relief until such sources of focal infection have been properly treated.

The influence of gross structural lesions, osteopathic lesions of the cervical and upper thoracic region, vertebræ and ribs must not be overlooked because they exert a powerful influence upon the blood supply, particularly the venous and lymphatic drainage and upon the autonomic nervous mechanism, which regulates the physiologic control of such functions.

Gross structural abnormalities of the intranasal chambers, such as deflected septum, enlarged turbinates or cellular turbinates, which cause deficient or abnormal breathing space, may cause and maintain head colds.

=Diagnosis.=—The diagnosis is usually easy. Nasal congestion with the usual “stuffy” feeling of the head, sneezing, headache, etc. are well known symptoms. On direct examination the nares are congested, there is a watery discharge and all of the membranes of the nasopharyngeal tract are congested.

=Treatment.=—If there is ever a demand for good, thorough and specific osteopathic work, certainly it is demanded in such cases. I am an advocate of thorough, deep relaxing treatment followed by specific adjustment in such cases.

Complete rest in bed with light diet and careful attention to the elimination are very essential. Perhaps the most difficult problem is to convince the patient that a head cold is really a serious disease and demands thorough and prompt treatment. Every ear, nose and throat specialist has had ample opportunity to know that most of the really serious complications of the head and neck result from the lack of prompt and proper attention to head colds.

The local treatment consists of irrigation of the nasopharynx followed by oil spray to protect from further irritation and the maintenance of proper drainage from the sinuses and middle ears. I am not an advocate of the so-called “antiseptic sprays” because they neither destroy bacteria sufficiently to be effective nor do they maintain drainage.

In all cases, the physician should be ever watchful for the complications and should not hesitate to call consultation of a specialist when such symptoms develop.

Purulent Rhinitis

Persistent inflammations of the nasal membranes are usually of a purulent nature or at least have had such a cause in the beginning.

=Etiology.=—Purulent rhinitis may be a result of an unsuccessfully treated infection of the nose or throat following some disease of childhood or early life. It may be due to infection at birth. Commonly there is a subacute or chronic sinus infection that maintains the infection of the nasal mucosa. Polyps, enlarged or cellular turbinates, adenoids or adhesions in the epipharynx, often retain the secretions and cause chronic rhinitis. In many cases I have found that osteopathic lesions of the cervical or upper thoracic region are effective causes of chronic rhinitis.

=The Pathology= consists of hyperemia, hypertrophy and exfoliation of the cellular membrane. The turbinates and all membranes become enlarged and thickened and the breathing space is usually greatly decreased.

=The Symptoms= are nasal obstruction, and mucous or mucopurulent discharge with usually hypersensitiveness, which causes sneezing and other symptoms common to “head colds.”

=Treatment.=—The same treatment as given above for acute rhinitis applies here. A thorough examination should be made for all of the various causes given above and the proper corrective treatment given for any or all such causes.

Chronic Hypertrophic Rhinitis

=Etiology.=—Chronic rhinitis is usually a result of an infective rhinitis and has for its cause any one or more of the various causes given above under purulent rhinitis.

=Pathology.=—The pathology in chronic rhinitis varies with the cause, but is usually characterized by a series of changes beginning with infection and hyperemia and followed by an actual and usually marked hypertrophy of the interstitial tissue. The posterior ends of the inferior or, less often, the middle turbinates are usually enlarged and extend backward into the pharynx.

=The Symptoms= are much the same as in purulent rhinitis, except that the purulent discharge is often not present. These cases usually suffer from chronic head colds, headaches and persistent nasal obstruction. The senses of smell and taste are usually impaired and there is a nasal twang to the voice.

=Treatment.=—In these cases, it is common to find osteopathic causes which prevent proper drainage from the head and neck and this is important because, if all the local causes are properly corrected, this is not sufficient to effect a cure.

Surgical treatment for the removal of polyps, synechia, adenoids, adhesions, correction of septum, or hypertrophied or cellular middle turbinates is often essential and certainly infected sinuses must be properly drained. We have had cases in which root abscesses seemed to be active causes, but it must not be thought that surgery and surgery alone is likely to cure chronic rhinitis, and I want to caution against the wholesale removal of turbinates for such conditions. The mere fact that the turbinates are enlarged is not sufficient reason for their removal. There has been a cause for this enlargement and turbinotomy or turbinectomy does not remove this cause. Cautery is worse, because it seldom accomplishes more than very temporary results and often leaves the membranes worse than before. Cautery destroys mucous membrane, leaving a dry and easily irritated surface which is often impossible to normalize.

The proper surgery, carefully done, followed by efficient osteopathic corrective work and thorough irrigation of the nasopharyngeal tract with the necessary oil spray protection after irrigation, will constitute efficient treatment. Treatment, thorough and long continued, will in due time restore nutrition, drainage and normal reflex nerve control to the tissues. Treatment after surgery is essential.

=Intranasal Treatment.=—Many cases are caused by the retention of secretions under the turbinates and in the superior vault. In all cases, therefore, it is essential to thoroughly free all possible retention cavities by means of a small cotton-wound probe before irrigation. The intranasal membranes are adrenalized and anesthetized and a thorough examination is made using a good reflecting lamp, nasal speculum and cotton tipped probe. Every part of the intranasal region is inspected for sources of purulent discharge, mucus collections, synechia and for hypersensitive areas. The probe is curved at the end and passed under each turbinate and drawn forward and backward with considerable pressure to insure that any collection of foreign matter is thoroughly removed. Every part of the intranasal region should be thoroughly treated in this way. The hiatus semilunaris must be kept well open to permit free antrum drainage and all other sinus openings should be kept free from any obstruction that may block the drainage. This particular technic requires great care and practice, but it is very effective and so commonly we have found that this work thoroughly done will reduce much and in some cases all of the turbinate hypertrophy rendering surgery unnecessary.

Atrophic Rhinitis

As the term suggests, this disease is just the opposite from hypertrophic rhinitis in that the membranes are shrunken, the nares are wide open and usually the membranes are coated with a mucopurulent discharge, accompanied by a bad odor. It is a chronic disease and progressive in nature.

=Etiology.=—Deficient nutrition, systemic or local, or some degenerative infective process constitutes the cause. Some cases may be traced to syphilis, but this is certainly not always the cause. Chronic sinuitis, the cause of which is some virulent infection, is often the cause. Too much or incorrect surgery and cautery is certainly a cause in many cases.

=Pathology.=—The marked atrophic appearance, the retracted turbinates, the excessive purulent or mucopurulent foul discharge are characteristic and diagnostic.

The tissues underlying the mucous membranes are shrunken, and atrophic and this tissue has usually been replaced, sometimes almost completely, by connective tissue, and thus the blood supply is markedly deficient.

=Treatment.=—In chronic cases, those in which the atrophy is well progressed, there is no hope of restoration to normal conditions, but I believe that the progress of practically every case can be stopped and that, in most cases, a permanent cure can be effected under proper treatment.

Every possible source of focal infection, such as sinuitis, pharyngitis, tonsillitis, etc. should receive proper attention promptly. After this has been done and sufficient time allowed for normalization, a blood count may reveal some other source of focal or general infection, which may be reducing the general resistance.

Auto-intoxication from some gastro-intestinal affection is commonly a cause and must receive proper attention. The general health of the patient must be restored and maintained.

Thorough osteopathic treatment must be given for any cause of lowered nutrition, local or general. The failure, I believe, in medical practice (They admit failure in this disease) is due to the lack of attention to the restoration of normal nutrition. Why drain a sinus and leave an atlas or upper thoracic lesion which decreases the local nutrition and leaves these membranes susceptible to further infection?

Before and after surgical drainage, irrigation of the nasopharyngeal tract. Thorough irrigation to cleanse every part. Hot irrigation (one gallon of salt mixture solution, salt 3 parts, borax 2 parts, and soda 1 part, a tablespoonful to the gallon at 118°F. to 123°F.) to cleanse, to free all parts from infection and to restore blood supply to the affected parts. Frequent irrigation, daily for a sufficient time to thoroughly sterilize and restore circulation. After each irrigation, an oil spray (any non-irritating petroleum oil) is applied freely to protect the membranes from irritation and further infection.

Before each irrigation a thorough probe treatment, as described under hypertrophic rhinitis, should be given that the membranes may be thoroughly freed from all retained secretions.

After the membranes are once clean, the sinuses free from infection and the blood supply reestablished, the treatment may be reduced in frequency to three times weekly, but the treatment must be continued for months or even years to effect a permanent cure. The patient can be taught to do his own irrigation after the disease is well under control. All irritating sprays, chemical cauteries, etc. must be avoided. The so-called “antiseptic sprays” do harm by irritating the membranes and certainly do no good, because they do not cleanse the parts. They only serve to deodorize, but actually accomplish nothing in the way of cure. It has been my experience that iodine and the silver salts in any of their various preparations are not efficient but that they actually do harm. My experience indicates that practically every case can be cured if the proper treatment is given for sufficient time.

Pharmacodynamics

If I may be pardoned for discussing things pharmacological in a text on practice, I want to urge that chemicals as such, are usually a failure in treatment. My results from various series of experimental work both laboratory and clinical, show quite conclusively that there are very few, if any, chemical substances that have actual value by virtue of their chemical properties alone. There are, however, cases in which chemical agents may be used to advantage to obtain desirable physical results and physiologic reactions.

The salt mixture mentioned above increases the solvent power of the water for mucus, pus, and other collected material and it also renders the water less irritating to the mucous membranes. Other than this, it has no value so far as I know. This solution is certainly not antiseptic or germicidal, further than that cleanliness may be considered an antiseptic procedure.

The phenol-glycerine (10% phenol and 90% glycerine) which we have recommended, is somewhat germicidal, non-irritating, except to the nasal mucosa, is a protectant to inflamed membranes in some instances and is also somewhat hygroscopic. These virtues to the limited extent that they may be of advantage, depend chiefly upon physical qualities.

Adrenalin in high dilutions (1 to 5000 to 1 to 10,000) is of value in retracting the erectile tissues of the nares for purposes of examination and for obtaining better drainage, etc. It also constricts the small blood vessels and thus reduces the chances for hemorrhage or absorption of narcotic drugs which may necessarily be used as local anesthetics. The effects of adrenalin are very temporary and it is, therefore, of little value in treatment.

Following irrigation I have used the petroleum oils (liquid petrolatum) to advantage as a protection to the mucous membrane. One-half gram each of menthol and camphor and two or three drops of cinnamon oil to the pint of this oil, is readily dissolved and produces a pleasant, soothing effect to inflamed membranes, but further than this, the added substances have no particular value. The above named chemical agents constitute, except in rare instances, my stock of “drugs” for treatment purposes.

Hyperesthetic Rhinitis—Hay Fever

There is perhaps no disease in which there has been more speculation concerning the etiology than in hay fever, and while osteopathy has accomplished a wonderful advance in the treatment of this disease, I am not sure that the cause or causes are yet thoroughly understood.

=Etiology.=—The theoretic causes of this disease may be expressed in the various names which have been given to it as follows: The term Hay Fever suggests that it is a febrile condition caused by hay pollen irritation. Peach cold, Rose cold, Rose fever, Rose catarrh, Rye fever and Ragweed fever suggest similar specific causes. Idiosyncratic coryza means nothing and this probably expresses what the theorists know about its cause better than any other name. Hysteric rhinitis suggests a probable psychic cause, which certainly does exist in some cases. If I may be pardoned, and I know I never will be, let me suggest just one more name—"Respiratory Reflex Inefficiency."

=Intoxications.=—Auto-intoxication from focal infections or from gastro-intestinal perversions certainly have an important influence either directly or as predisposing factors and should always be carefully considered in treatment.

=Osteopathic Lesions.=—Osteopathic lesions, such as interosseous, muscular and ligamentous, seem to function as predisposing causes by their general effects upon the system. It seems probable that their effects upon the organs of metabolism and elimination are of greater importance than any direct or specific effect in causing the immediate symptoms. In practically all cases lesions of the upper thoracic vertebræ and ribs and of the cervical region are present. It is my opinion that such lesions are more often secondary than primary.

=Respiratory Reflex Inefficiency.=—Measurement of nerve force in these cases shows that none are really possessed with "an excess of nerve force," but that practically all vary from two-thirds to four-fifths normal, showing that probably all cases are deficient in nerve force.

This instability of the nervous system can be explained, I believe, in the theory of peripheral reflex insufficiency. As evidence of this the following facts may be cited:

1. It is known that peripheral irritation of almost any nature, to the mucous membranes of the nasopharyngeal tract, will excite an attack in susceptible individuals.

2. That any treatment which tends to increase the resistance of these membranes will prevent or relieve an attack.

3. That peripheral inhibition to these surfaces will temporarily relieve an attack.

4. That complete normalization of these membranes will make the patient resistive to the so-called specific irritants, such as pollen, dust, etc.

5. That the mucous membranes of the entire respiratory and gastro-intestinal tract react to irritants to bring about "the hay fever state" and that any treatment which tends to normalize these membranes, renders the patient more resistive to hay fever attacks.

=Exciting Causes.=—There is no doubt that various air-borne irritants, such as pollen, dust, chemical fumes, emanations from animals, etc., act as exciting causes of acute attacks, and yet there are cases that develop acute attacks out of season or at a time when it seems that there could be no air-borne irritation. From evidence which will be offered later (see prognosis) I am led to believe that probably all susceptible cases can be made entirely resistive to the air-borne irritants.

Pathology

=Functional Pathology.=—Certainly in this disease there is ample evidence of marked perversions of function or functional pathology. Kyle believes that in many cases the cause of local irritation lies in "some chemical change in the constituents of the mucus-secreting glands," and "it is a well known fact that in many cases of hay fever the irritation is not limited to the nasal mucous membrane. The eyes and mucous membrane of the stomach and bladder, and even the intestines may be markedly irritated."

These chemical changes in the secretion of the mucous membranes, together with the excess of uric acid would seem to point either to a general perversion of the secretory mechanism or to a deficient elimination, or to both. The periodic occurrence may be accounted for by assuming that the systemic strain is sufficient to initiate the symptoms. The fact that the attack is actually delayed

or hastened in susceptible individuals by the late or early beginning of hot weather, and that these cases get relief by going to a more moderate climate is further evidence of this.

Again we are reminded of Dr. Still's teaching, that the body maintains its own chemical laboratory which adjusts or tends to adjust its work to the needs of that body, but under abnormal strain this adjustive mechanism may fail to meet all of the demands of function. It seems here that the osteopathic concept may easily include all environmental causes as well as internal causes in the predisposition to deficient function or disease.

=Structural Pathology.=—During the attack there is a general catarrhal inflammation of all nasopharyngeal membranes, accompanied by a watery discharge and marked swelling of the turbinates. Sensitive areas may be found on the middle turbinate and opposite wall of the septum. Probably it is this hypersusceptibility to irritation that causes the attack from the air-borne irritants.

The pseudo-membrane which may be found covering a part or all of the mucous membranes of the nares probably results from this irritation and is formed for the purpose of protection.

=Clinical Types.=—Clinically, three rather indefinite types of hay fever may be recognized, viz.: Vernal, those cases which have their attack sometime during May, June or July; Autumnal, in which the attack occurs in August or September and usually lasts until the beginning of cold weather, and an indefinite or pseudo form occurring at any time of the year, with no characteristic attack, as in the other forms, but with indefinite symptoms resembling hay fever.

=Symptoms and Diagnosis.=—Patients usually go to the physician self diagnosed. The characteristic sneezing, the watery discharge from the nose, and the irritation of all membranes of the nasopharynx and conjunctiva will serve to make a diagnosis in most cases. Direct examination will reveal the nasal congestion and other characteristic pathology as described above.

=Termination.=—Most cases of the autumnal form, unless successfully treated, continue with equal or increased severity until after the first or second frost, when they usually terminate in asthma, bronchitis or sinuitis, which lasts for several weeks or months. Each year the attack lasts longer and is more severe and the asthma occurs earlier and is more severe.

Treatment

=Intranasal Surgery.=—Intranasal abnormalities, such as deflected septum, spurs on the septum, hypertrophied turbinates, polypi, etc., which materially reduce the breathing space, usually demand surgery. Nasal surgery, carefully and properly done, is always a great aid and often absolutely essential to the successful treatment of hay fever and asthma, but nasal surgery carelessly done frequently does more harm than good.

The correction of a deflected septum or the removal of a spur on the septum by submucous operation often aids materially in the prevention of pressure irritation, increases the breathing space and normalizes drainage from the sinuses.

Surgery is therefore very essential in many cases of hay fever, but surgery is never the all essential part of the treatment, because if the proper after treatment is not given, the surgery alone will seldom result in either temporary relief or cure.

=Focal Infection.=—The importance of focal infection of the sinuses, tonsils, teeth and occasionally other parts, such as the nasal cavities, epipharynx, middle ear and mastoid cavities cannot be overestimated. Such conditions may be effective in causing hay fever, by causing direct infection of the membranes of the nasopharyngeal tract or by auto-intoxication.

=Digital Surgery,= for the removal of adhesions in the posterior nares and pharynx, is in my opinion, very essential, and this work should be done thoroughly. Massage of the soft palate or pharyngeal walls is of no particular value. All adhesions and adenoid tissue must be removed because this removes an effective source of constant irritation and focal infection and tends to normalize the direct and reflex nerve mechanism.

The practice of the radical intranasal technique as originated by J. D. Edwards, D. O., is indicated, I believe, in some cases in which the crushing of cellular middle turbinates, or the breaking of adhesions is indicated, but I am not yet ready to accept this theory of "curetting" the mucous membrane by radical digital technique. The fracture of the turbinates is not necessarily a bad technique provided they are properly readjusted as Dr. Edwards does it, but to fracture and not readjust is a dangerous practice. The efficiency and safety of any method depends upon the operator's definite knowledge of what needs to be accomplished and how it is to be done.

There are contraindications to digital, as well as any other kind of nasopharyngeal surgery, such as: (1) Acute infection of any part of the nasopharyngeal tract; (2) evidence of sinus involvement; (3) septal deflections, spurs and hypertrophied turbinates, which would not permit such work without undue trauma.

There are certain other precautions such as thorough cleanliness of the parts to be treated; aspiration of the sinuses before and afterward, and the use of a finger of sufficient size which will not produce undue trauma. In my opinion very few doctors have such fingers.

Failure in accomplishing results is due to three things, viz., (1) Insufficient knowledge of diagnosis and prognosis; (2) insufficient knowledge of what should be accomplished and the technique of doing it, and (3) the necessary additional or supportive treatment.

It is a great mistake to think that the removal of adhesions in the pharynx or nares is sufficient, because if this is not followed by the proper supportive treatment, no results or even bad results will frequently occur. This treatment is not a massage in any sense, but a definite operative procedure and requires as much care and skill as the removal of adenoids or tonsils.

Space will not permit an explanation of the digital technique and the radical treatment should not be attempted without some definite knowledge of the methods and technique.

=Intranasal Treatment.=—The intranasal method of treatment as explained above under hypertrophic rhinitis is very effective and if carefully and thoroughly done is in most cases just as efficient as intranasal digital surgery. This treatment followed by irrigation and oil spray and nasal packing will be found effective in most cases if the treatment is properly done.

=Nasal Packing.=—Thorough packing of the nasal cavities after all sources of focal infection have been removed and after thorough cleansing has been done, by means of long strips of absorbent cotton is effective in reducing the swelling and irritation.

=The Radical Packing Method.=—This method can be done best in a hospital. The nares are prepared as for surgical operation, by complete retraction of all erectile tissue, thorough cleansing by irrigation and the application of a local anesthetic. Anesthesia need not be complete. A careful examination is then made for any synechia, or focal infections. Packing should never be done until the doctor is sure there is no sinus involvement. The entire nasal cavity is then packed very firmly with sterile gauze. This is best done by means of a special packing instrument or long nasal packing forceps, using narrow gauze contained in tubes. In some cases the nasal cavity is lubricated before packing.

The packing should be done early in the morning and removed just before bed-time, so that the patient may sleep. This treatment is repeated daily until all signs and symptoms of nasal irritation are gone and then replaced by irrigation and oil spray.

If this treatment is properly done, there will be a complete sloughing of the pseudo-membrane followed by a restoration of normal and resistive tissue. The results of our two years' experience (we have tried this on only a few patients each year) are very encouraging. Relief from the symptoms are very prompt and seemingly more permanent than from other methods.

=Treatment of Auto-intoxication.=—All sources of focal infection are thoroughly treated. Sinus infection is very common and must receive proper attention before any other treatment can be effective.

Our experience shows that many cases have auto-intoxication of gastro-intestinal origin. The hospital care of such cases makes possible the thorough cleansing of the colon by irrigation and the reestablishment of an acid producing flora which seems to prevent fermentation.

=Osteopathic Corrective Work.=—Thoroughness of treatment for the removal of all causes is the secret of success. To successfully remove the immediate sources of auto-intoxication by treating a sinus infection or by thoroughly freeing the colon from fermentation products means only temporary results if the underlying causes are not corrected. A thorough osteopathic examination is necessary to determine such causes and certainly such treatment should not be neglected.

Correction of all cervical and upper thoracic lesions and particularly the clavicles and ribs is important. These lesions seem to be the result rather than the cause, but normal respiratory functions seemingly cannot be maintained unless such treatment is done.

Sinuitis

Acute or chronic inflammatory disease of the nasal accessory sinuses with or without suppuration is more common, I believe, and is responsible for more complications and chronic affections of the nose and throat than is generally known.

=Etiology.=—The cause in most cases lies in unsuccessfully treated acute infections involving the nose and throat. Abnormalities of the nasal respiratory passages such as deflected septum, enlarged or cellular turbinates, adhesions resulting from cautery or careless surgery, causing deficient drainage, constitute the local causes. Underlying some of these direct causes, lesions of the cervical region which impair the nutrition to and drainage from the head are to be considered.

=Symptoms and Diagnosis.=—Acute or chronic headaches and neuralgic pains of the head are common symptoms. Acute sinuitis of the frontal sinuses is accompanied by marked and persistent frontal headache and pain in the eyes. In infections of the maxillary sinus there is usually pain over the affected part, but there is often referred pain to other parts of the head. Sphenoidal sinuitis usually causes general headache with no definite location.

By direct examination of the nasal cavities a purulent or mucopurulent discharge may be seen and the source determined. In many cases, however, the pus may be retained or insufficient in amount to detect by direct examination.

Transillumination in a dark room by means of a good transilluminator will usually show a darkened area over the affected part. The average battery equipments commonly sold for this purpose are of little value. The X-ray plate when properly done, is more dependable than the transilluminator.

In some cases, all of these methods fail to locate the affected sinus and the cause can be found only by opening into the sinuses, aspirating with a catheter and making microscopic examination of the aspirated material. The microscope is indispensable for this work. Every suspicious discharge should be stained until pus is found and except in well defined cases, this is the only practical method of positive diagnosis.

=Treatment.=—Local treatment of the nasal cavities by retracting the turbinates and irrigation will be successful in many cases, but unless there is a large normal opening the pus will not drain sufficiently and probe treatment is required. In acute cases in which the pain is marked, osteopathic treatment of the cervical region, deep relaxation of the submaxillary structures and the application of heat over the affected part, together with the local nasal treatment should be given, but if this does not relieve the pain within twenty-four hours, the sinus should be opened and thoroughly drained. If efficient drainage is not established early the symptoms will usually increase until the pain is almost unbearable and serious complications may result.

In practically every case of acute sinuitis, I believe it is best to make a good, free opening into the affected sinus first and secure complete drainage by catheter aspiration. If this is properly done every case will recover much more quickly and without complications or danger of chronic infection.

Non-Suppurative Sinuitis

Cases of non-suppurative sinus involvement are not at all uncommon. The so-called “Vacuum sinuitis” which results from a closure of the normal opening, resulting in inflammation without pus formation, is responsible for many of the complicated cases of referred pain, which are so often improperly diagnosed. Chronic headaches and the various symptoms of fifth nerve affections, the neuralgias of the head, are frequently caused by non-suppurative sinus involvement.

=Treatment.=—The treatment consists of establishing good drainage and proper ventilation of the affected sinus or sinuses followed by thorough intranasal treatment as explained above. The osteopathic corrective work must not be neglected.

Syphilis of the Nose

In osteopathic practice syphilis is not a common disease. The occurrence of syphilis of the nose is still more rare but certainly should be recognized.

=Diagnosis.=—The local lesions of the nose are of two types, those of acquired syphilis and of congenital syphilis.

There are three characteristic manifestations of acquired syphilis as follows. The primary lesion or hard chancre is a firm, indurated ulcerated mass with only slight discharge. Chancre of the nose is exceedingly rare. In secondary syphilis there is the mucous patch, the result of mucous membrane necrosis. In tertiary syphilis the local lesion is the gumma or more commonly, the ulceration left from necrosis of the gumma. These lesions may appear from a few to many years after the initial infection, but they never follow immediately. The lesions may appear on almost any part of the intranasal structures. They resemble the lesions of atrophic rhinitis but in atrophic rhinitis there is never the extent of destruction that so frequently results from tertiary syphilis.

=Treatment.=—It has been my practice to refer all suspected cases to Dr. F. J. Stewart for differential diagnosis and treatment and his method of the use of salvarsan has proven efficient.

Epistaxis—Nose Bleed

The causes of nose bleed may be divided into two general groups, local and constitutional. The first group consists of trauma directly to the nose either external or internal, from nasal operations and other causes. The presence of a cluster of thin-walled veins on the anterior part of the septum which readily rupture from slight cause, constitutes perhaps the most common cause of nose bleed. The ulcers of atrophic rhinitis or syphilis occasionally cause bleeding. Malignant growths of the nose may cause frequent and profuse hemorrhage. The constitutional causes of epistaxis are, the acute fevers, cardiac and arterial diseases, which cause excessive tension; and cases of altered composition of the blood such as the anemias, malaria, purpura, chlorosis, hemophilia, etc.

=Diagnosis.=—Direct examination of the nose will usually reveal the cause. If there are no signs of trauma or rupture of the anterior group of vessels and the bleeding does not respond quickly to packing of the affected side, there is either a rupture of a large vessel, which requires long continued packing, or it belongs to the class of constitutional disease.

If there is evidence of some necrotic disease of the nose or if there are areas of exposed bone or cartilage from careless surgery, these may usually be seen and the point of bleeding located.

=Treatment.=—Cold applications, irrigation of the nares with cold normal salt solution and the application of an absorbent cotton or gauze pack is usually sufficient to stop the average case of epistaxis from any cause. The direct application of cold to the lower cervical region will cause capillary restriction.

There are many cases in which the membranes of the nose have lost their tone due to various irritants or from deficient nutrition to the parts. These are cases of a wholly different type from that of the well known necrotic diseases such as atrophic rhinitis and syphilis. Hay fever is a result of such a cause. The treatment in such cases consists of removing any local causes or osteopathic lesions and then normalizing the resistance of the membranes by the methods described under the treatment for hay fever.

The treatment for those cases of epistaxis due to constitutional disease depends wholly upon the causative factors and the proper treatment of these. Any local treatment in such cases will be expected to produce only temporary results.

Diseases of the Nasopharynx

The nasopharynx may be the location of acute or chronic inflammations, neoplasms, malignant or nonmalignant, processes of atrophy or hypertrophy, adhesions, etc. It is important to remember that the nasopharynx admits the Eustachian tubes and supports four superficially located ganglia of the fifth nerve.

=Acute Nasopharyngitis.=—Acute inflammatory processes of this region may result from rhinitis, infections of the lower pharynx, focal infections of these parts or from direct involvement of its own structures.

The symptoms are post nasal tenderness and mucus dropping. Some patients experience the sensation of a foreign body in that location. The thick, adherent collections of mucus are difficult to dislodge and sometimes are so persistent that they cause nausea. There is usually occlusion of the Eustachian tubes, resulting in partial deafness, tinnitus and often dizziness.

=The Treatment= consists of thorough cleanliness by irrigation and osteopathic corrective work to the cervical region. It is also essential to keep the anterior neck structures particularly those of the submaxillary region, thoroughly relaxed to maintain efficient drainage.

Chronic Nasopharyngitis

This is one of most common diseases of the nasopharyngeal tract, causative of many complications and yet perhaps the least recognized in proportion to its significance. The frequent occurrence of adhesions of the pharyngeal fossæ, hypertrophied membranes, enlarged spongy extensions of the inferior and middle turbinates (the posterior turbinate bodies) occlusion of the orifice of the Eustachian tubes and chronic, excessive secretion of thick mucus all show that this disease has either gone unrecognized or at least has not received proper treatment.

=Treatment.=—Complete surgical removal of all abnormal growths, adhesions, etc. as described under the treatment of chronic non-suppurative otitis media and this followed by thorough irrigation and other methods of local treatment described above are efficient. The successful treatment of this disease requires time. There has been a partial or, in some cases, almost a complete loss of the normal functions of the nerve reflex mechanism of these parts, peripheral reflex inefficiency and this must be restored. Efficient and long continued treatment of the lesions commonly found in the cervical and upper thoracic regions will do much to restore these normal functions, but this alone without the surgical treatment will never effect a permanent cure. Neither will the surgery and local treatment alone effect a cure. The whole treatment is required.

Adenoids

Adenoids are the hypertrophied lymphoid tissue of the nasopharynx. They occur commonly in children, as a result of acute inflammations. Possibly the suckling process of the child produces a partial vacuum of the epipharynx and thus causes excessive blood supply to the part and therefore excessive growth of these soft tissues.

Adenoids, however, are not confined to children but frequently occur in adults. In all cases they are a source of much annoyance and often the cause of acute and chronic disease.

=Symptoms and Diagnosis.=—Mouth breathing, head colds, partial deafness, etc. are the common symptoms. The flattened nose, the high arch of the hard palate and the stupid appearance of the face are diagnostic. By direct palpation to the nasopharynx the nature and extent of the adenoid mass can be determined and this is the best method of diagnosis.

=Treatment.=—Many methods of non-surgical treatment have been employed, but there is nothing as satisfactory as complete surgical removal. Adenoid tissue has no known function different from that of other lymphoid tissue and there is always sufficient to perform any necessary function without excess of adenoid growth. The excessive adenoid growth is in every case a detriment to normal development, because it impairs nasal respiration and usually causes chronic nasopharyngitis and thus reduces resistance against all diseases of childhood. There is therefore, no excuse, much less a reason, why excessive adenoid growths should not be removed surgically, provided it is properly and thoroughly done.

The operation for removing adenoids requires in children, a general anesthetic. In adults, a local anesthetic is used by some operators. I have found it best to first break the adenoid mass away from the side walls of the pharynx digitally. A LaForce or Gradle adenotome is then used to remove the adenoid mass. If either of these instruments is properly used it will always remove the greater part of the adenoid mass without undue trauma or injury to any of the pharyngeal structures. Curets should never be used because they almost never remove the adenoid mass properly, but they usually do injure the pharynx. Many cases of pharyngeal adhesions, Eustachian tube occlusion and nasopharyngitis result from direct injury caused by curets.

After the adenoid mass has been removed the finger is inserted into the pharynx and any adenoid growths in the posterior nares are removed. The pharyngeal fossæ are also thoroughly freed from adenoid tissue and adhesions and the orifices of the pharyngeal portions of the tubes are gently dilated. This method insures complete removal of all excessive adenoid tissue, and normal functions of the nasopharynx. Adenoids thus removed do not return.

After the surgical work has been completed the nasopharyngeal tract should be thoroughly irrigated with hot salt mixture solution. This thoroughly cleanses the membranes, hastens healing, prevents hemorrhage and avoids post-operative infection. Irrigation of the nasopharynx should be continued for some days or until all evidences of inflammation have ceased. The pharynx should then be examined to be sure that no adhesions have developed from inflammation, but if the operation is carefully done, complications will never result.

Diseases of the Oropharynx

Acute Pharyngitis

Acute inflammations of the pharynx alone or in common with inflammations of other parts of the nasopharyngeal tract are common. This disease is most common as a result of the acute infections affecting the nose and throat.

=Etiology.=—The predisposing causes are focal infections of the nasopharynx, such as tonsillitis, sinuitis, etc. Deficient nutrition or anemia of the pharynx or systemic anemia are common causes. Lesions of the cervical, upper thoracic and hyoid are common predisposing causes. Undue exposure of the neck in susceptible persons or too much or too tight clothing about the neck may also

predispose to inflammations of the pharynx.

The exciting causes are the acute infections, colds and focal infections. Perhaps the most common exciting cause is tonsillitis, acute or chronic.

=Symptoms and Diagnosis.=—The characteristic dryness of the pharynx, pain and persistent coughing are diagnostic. Upon direct examination, the reddened, swollen appearance of the pharynx and posterior pillars can be seen.

=Treatment.=—The treatment should be general and local and should be determined by the causes and conditions present. This disease is usually an acute infection and like other acute infections, the usual systemic treatment should be applied.

The local treatment consists of thorough cleansing of the nasopharynx (by irrigation if the patient can permit) and the frequent (or occasional as required) use of some gargle until the inflammation has subsided. Any cleansing nonirritative solution may be used for a gargle. Equal parts of peroxide, alcohol and glycerine, a tablespoonful to a half glass of very warm water or ten to fifteen drops of phenol-glycerine to a half glass of warm water will make a good cleansing gargle.

The osteopathic treatment consists of corrective work to the cervical, upper thoracic and hyoid and thorough relaxation of the submaxillary musculature to obtain good venous and lymphatic drainage. If sufficient care be taken to avoid trauma, digital stretching of the soft palate and pharyngeal muscles by the use of the finger internally, is very efficacious.

Chronic Pharyngitis

Chronic pharyngitis may be hypertrophic, atrophic or granular. In hypertrophic pharyngitis the pathologic changes have passed beyond the stage of hyperemia and there is always hypertrophy or hyperplasia, usually the latter, of the pharyngeal membranes. These changes in most cases, have extended to and involved all of the nasopharyngeal membranes.

Chronic granular pharyngitis, or so-called clergyman’s sore throat, has a similar pathology to that described above, but with swollen and inflamed lymph follicles. This condition seems to be a result of excessive use of the voice.

Chronic atrophic pharyngitis has a similar etiology and the diagnostic signs are also similar to atrophic nasopharyngitis with which it is usually associated.

=Etiology.=—The causative factors are similar or the same as those of nasopharyngitis. Lesions of the cervical and upper thoracic and chronic focal infections such as tonsillitis, sinuitis, etc. are the common causes.

=Treatment.=—The nature of the treatment should be determined by the causes found. The nature of the pathology requires long continued treatment and careful attention to all causes. Thorough osteopathic corrective work, the removal of all sources of focal infection, proper attention to any gastro-intestinal perversions which may be causing auto-intoxication and thorough cleanliness of the parts by gargling with some cleansing, non-irritating solution and by irrigation.

In most cases there is a considerable collection of adhesions in the nasopharynx or posterior nares or in both. Enlarged “posterior turbinate bodies” and the extension of the inferior turbinates into the pharynx are also common results of the hypertrophic process. Complete surgical removal of this excess tissue and the after treatment as described above under chronic nasopharyngitis are frequently required to obtain complete and permanent results.

These cases can be successfully treated if the proper attention is given to all possible causes in each individual case. It is the individualization, the specific and detailed attention to the cause or causes, and such treatment continued for sufficient time, that will obtain results.

In atrophic pharyngitis, normal nutrition to the parts and usually to the entire system must be restored. Many such cases are secondary to systemic anemia or to rheumatic intoxication. A careful examination should be made for evidence of systemic causes. In many cases, I believe that thorough osteopathic corrective work applied to the mid and lower spine is the most essential part of the treatment. Other than this the local treatment as described under atrophic rhinitis applies here.

Tonsillitis

There is perhaps no other organ of the body, diseases of which have caused a greater variance of opinion relative to treatment than the tonsils. There are those who believe that every hypertrophied, atrophied, or infected tonsil together with its fellow of the

opposite side should be removed. There are also those who believe that no tonsils, regardless of their pathology, should ever be removed. These are the radicals and their views are not at all in keeping with present day facts.

Those physicians and surgeons who have tried to arrive at some safe conclusion on this subject, believe that there are certain methods of non-surgical treatment which are effective in many cases and they also believe that in other cases, tonsillectomy is imperative.

=Functions of the Tonsils.=—Many and varied functions for the tonsils have been held by various theorists such as: the absorption of the products of salivary digestion; the secretion of an amylolytic ferment; that they are atavistic structures and therefore have no function; that they eliminate systemic toxins; that they serve as culture tubes for the production of vaccines; that they protect the deeper cervical tissues from bacterial invasion; the theory of internal secretion and a score of other theories which so far, have never been substantiated by either clinical or experimental evidence.

The hematopoietic theory or the theory of blood formation has a rather definite basis because such a function would be possible from the histologic structure. The formation of small lymphocytes has been attributed to tonsil tissue (Flemming) and this view has been generally accepted. Some of the lymphocytes however, find their way through the epithelial walls into the crypts and are discharged as “mucous plugs”, while others are carried by the efferent lymphatics into the circulatory system. In this respect, the tonsils, like other lymphoid tissue, produce lymphocytes which are essential constituents of the blood. This function is particularly marked during the growing period, but this function is also highly developed in all lymph nodules during this period, and in the growing child there is an abundance of such tissue and thus it seems that the tonsils, while important to the growing child, would not be at all indispensable structures.

Some physicians claim to have observed deficiencies in growth and development of children whose tonsils had been removed during the first ten or fifteen years of life, but this is not commonly accepted. The tonsils have their greatest cellular activity during the growing period and unless chronically hypertrophied they atrophy during adult life.

Tonsillectomy

We may safely conclude from this evidence, that in the growing child, it may be well to retain the tonsils providing they are not directly affected in such a way as to endanger the general health of the child, but that there is little, if any, danger in their early removal. In adults, there seems to be no reason why they should not be removed in cases in which there is evidence of involvement beyond restoration by treatment or those cases in which there is evidence of toxic absorption.

When surgical removal of the tonsils is indicated, the complete removal or tonsillectomy should always be done. A careful and complete enucleation of the tonsils when properly done will never be followed by any untoward results other than the temporary surgical sore throat. There is never any excuse, much less a reason, for partial removal of the tonsils or tonsillotomy, because such operations never accomplish the desired result and they nearly always require tonsillectomy later.

In association with a reputable vocal teacher I have studied the results of tonsillectomy on the voice. In none of the twenty cases studied was there any impairment following the operation, but on the other hand sixty per cent were improved either in range of pitch, quality or endurance, in addition to their being more free from laryngitis, pharyngitis, etc. for which the operation was done. Doctors Ruddy, Edwards and Reid of our profession have told me of similar experiences, so I am certain that tonsillectomy properly done will in selected cases, improve the voice.

Acute Tonsillitis

Acute tonsillitis is an acute infectious and often a contagious disease characterized pathologically by inflammation of the tonsils. Some authors differentiate between follicular tonsillitis in which the crypts or lacunæ are involved, and parenchymatous tonsillitis in which the parenchyma is involved.

=Etiology.=—The predisposing and exciting causes are the same as in other acute infections of the upper air passages except that there is usually a chronic tonsillitis as a result of some previous attack.

=Symptoms and Diagnosis.=—The symptoms also are similar to other acute infections of the nasopharyngeal tract, with sore throat, variable temperature, headache, etc. By direct examination of the pharynx, the protruding masses with white or yellow patches are readily seen.

=Treatment.=—Infection, drainage and elimination are three words inseparable in the therapeutics. The local treatment (I doubt if many will agree) in either acute or chronic tonsillitis is essentially the same—radical aspiration drainage. In all cases, except young children who will not permit it, I place a vacuum cup directly over the tonsil and apply as much vacuum as can be obtained. This treatment will, when properly done, empty the crypts of all pus. This accomplished, each crypt is probed with a cotton applicator dipped into phenol-glycerine.

Cervical and upper thoracic treatment and deep relaxation of the sub-tonsil tissues to increase the normal blood supply and to decrease congestion by drainage elimination are essential. The lower thoracic and lumbar should receive due attention for the purpose of increasing general elimination. The diet and other treatment are no different from that in other infectious fevers.

Peritonsillar Abscess

(Quinsy Sore Throat.)

Peritonsillar abscess results from the collection of pyogenic bacteria and pus formation between the tonsil and the pillars of the fauces. It is perhaps a result of the closing of an infected crypt causing deep penetration of the pus.

=Diagnosis.=—The symptoms are those of acute tonsillitis but usually more marked and with one tonsil decidedly more protruding than the other. In some cases the location of the abscess can be seen and it is comparatively easy to open with a knife or probe, but in many cases the abscess is so situated that it cannot be located except by exploratory probing.

=Treatment.=—Drainage by direct incision of the abscess pocket is indicated as early as a definite diagnosis can be made. There is no definite technic to be followed except to observe certain general principles. If the “pointing” of the abscess can be located, it is comparatively easy to make a good, free, direct incision and accomplish complete drainage. In many cases the only way to locate the pocket is to employ a probe or small, long, scalpel and explore between the pillar and tonsil until the pus pocket is found. As soon as this is located the pus pours out around the probe and this gives the location. Free drainage by means of a liberal incision should then be made. Aspiration of the pus pocket and filling with phenol-glycerine is effective after drainage has been obtained, but a liberal drainage must be maintained.

The non-surgical treatment as described under acute tonsillitis is to be applied here.

Chronic Tonsillitis

Chronic tonsillitis usually is the result of one or many attacks of acute infections of the tonsils. Occasionally cases of marked chronic tonsillitis occur in which the patient denies ever having had an acute attack.

The pathology consists of hypertrophy of the lymphoid tissue and connective tissue.

=Diagnosis.=—The purpose in diagnosis is not to determine whether the tonsil is hypertrophied but to determine whether the tonsil is causing any local or general physiological perversions and if so, whether local treatment or surgery should be applied.

The direct examination should be made very carefully, because otherwise a bad tonsil may be readily overlooked. The mere fact that a tonsil is large or has open crypts from which a whitish mass may be expressed does not mean that such a tonsil is directly responsible for local or systemic physiologic perversions.

The examination should be made by means of a tongue depressor, tonsil retractor and a good head mirror and reflecting lamp. Every part of the tonsil and surrounding pillars should be carefully examined. Firm pressure applied against the tonsil from in front and behind will often force material from the crypts or out around the capsular margin. Any such material thus expressed should be examined microscopically. By probing the crypts with a small pointed cotton-wound probe and staining the material obtained, the condition of the deep parts of the tonsil can be determined.

The symptoms in every case, are to be considered with the microscopic findings, but there are cases in which either of these, together with appearance on direct examination, is sufficient to determine the advisability of tonsillectomy.

In general, we may say that the following factors would indicate tonsillectomy.

1. Chronic, recurrent tonsillitis with or without complications, which does not respond to non-surgical treatment.

2. Positive evidence of arthritis of any form with microscopic evidence of some virulent organism, such as staphylococcus, streptococcus or long-chain pneumococcus, present deep in the tonsillar tissue.

3. Any persistent discharge of pus from the tonsil in which the microscope shows the presence of virulent bacteria and which will not be relieved by treatment.

4. Markedly hypertrophied tonsils which directly interfere with the voice, deglutition or respiration and which do not respond to treatment.

5. Persistent focal infections of the middle ears, or sinuses or root abscesses which do not respond to treatment and in which case there is a virulent infection of the deep parts of the tonsil, shown by microscopic examination.

The above are only general conditions and there are probably many other indications or groups of symptoms that would indicate tonsillectomy. In most cases, unless the findings show positively that tonsillectomy should not be delayed, we advise treatment. If treatment does not restore to normal, it will probably reduce the time of the surgical sore throat following the operation.

=Non-surgical treatment.=—The local direct treatment, as we practice it, consists of: 1. Direct aspiration by means of the tonsil cup, applying from fifteen to twenty inches of vacuum. 2. Application of phenol-glycerine by means of cotton applicator to the full depth of each crypt. 3. Irrigation of the crypts by means of a catheter and hot salt mixture solution. 4. Syringing of the crypts by means of the catheter and phenol 10%, alcohol 20% and glycerine 70%.

The digital treatment of the tonsil consists of: 1. Applying pressure against the anterior pillar thus forcing the contents out of the tonsil, the Ruddy method. 2. By the bidigital technic, the front finger of one hand inside, posterior and inferior to the tonsil and the fingers of the other hand outside exerting deep pressure and opposing the finger inside. In this way the tonsil can be lifted forward and upward and its contents expressed. The digital treatment is not as effective as that described above.

The osteopathic corrective treatment consists of adjustment of the atlas and axis and the mandibular articulation and the obtaining of free movement of the hyoid and the relaxation of the submaxillary musculature and other deep structures.

This treatment, if followed persistently, will relieve the local symptoms of a very high percentage of cases of chronic tonsillitis, and in many cases even the systemic complications will be relieved. Whether in cases of systemic absorption this is the preferable treatment I am not sure, because, once the local condition is improved the patient will usually refuse operation and even if the physician finds definite evidence of toxic absorption he cannot convince the patient that his tonsils require surgery.

MENTAL DISEASES

BY

L. VAN H. GERDINE AND A. G. HILDRETH.

INTRODUCTION

The subjects herewith presented, while including certain of the most important sections of mental disease, make no claim to completeness either in the subject matter presented or in the attempt to cover the entire field of the psychoses. They cover those portions, however, with which we have come in closest touch at the Still-Hildreth Sanatorium, and in which we have the most complete records. I have been aided in the compilation of the essential facts and statistics by the able staff of the institution and wish to acknowledge especially the valuable cooperation of Dr. C. M. VanDuzer in the Dementia Praecox group, Dr. H. P. Hoyle in the Manic Depressive group, Dr. B. L. Jemmette in the group entitled Delirium, Confusion and Stupor, Dr. J. C. Snyder in the Senile Dementia group and Dr. G. S. Elkins in the Involutional group. The opinions concerning each type held by Dr. A. G. Hildreth are appended under its appropriate heading. I wish to state emphatically that the sole treatment carried out in the Macon Institution is specific corrective work upon spinal lesions, and it is upon this treatment that the statistics are based which are to be found throughout the text. These records cover more than 700 cases, including complete histories of the patients with the physical and mental findings on examination; these represent, therefore, by far the largest body of statistics ever accumulated in the study of osteopathic results in mental disorders. While the results naturally vary in different types of mental disease the grand total shows that more than one-half of all patients admitted recovered. Details for each group will be mentioned under its appropriate heading. While adjuncts such as diet and hydrotherapy have been utilized; we certainly cannot attribute any curative value to their influence.

It should be further emphasized that in no case whatsoever has medicine been used as a curative agent. And the same may be said of surgery. It has indeed been conclusively proved even in the medical world that medicines and surgical procedures are absolutely ineffective; from the osteopathic viewpoint this of course is perfectly reasonable since the theory calls for definite lesions as causative factors and these lesions can hardly be reached other than by the osteopathic method of correction. The results obtained, therefore, could only be attributed to the genuine osteopathic principle enunciated by Dr. A. T. Still who kept in close touch with the work and gave it his approval up to the time of his death. He had always maintained that the osteopathic principle could accomplish remarkable results in this field and considering the previous inefficiency of any other method his confidence has been fully justified.

Dementia Praecox

This condition refers to mental disorders arising usually during the period of puberty or adolescence, therefore, between the ages of fourteen and twenty-five for the most part, although apparently similar cases may arise in later years. The term dementia refers to mental deterioration and enfeeblement, while “praecox” signifies adolescence, though some writers infer that the term praecox may be used to indicate the early or precocious development of the mental enfeeblement. Certain it is that in most cases deterioration, with its resulting symptoms of mental enfeeblement giving rise to the term dementia, usually occurs in time, though by no means always early. It is a chronic progressive disease which may terminate in a complete loss of mentality; in other cases it may become arrested in any stage and remain so permanently; in still others it may recover, though this is rare. By reason of the variability of the symptoms, three groups are generally recognized, first suggested by Kraepelin. Each is differentiated by more or less characteristic symptoms and referred to under the head of the Hebephrenic, Catatonic and Paranoid types, although all have certain symptoms in common and there are mixed types.

=Etiology.=—According to the authorities some form of hereditary factor can be found in some fifty per cent or more of all cases; this is supposed to create a predisposition, a natural weakness of the nervous system, which renders it unable to bear the ordinary storm and stress of life, so that the mechanism becomes according to the French expression, “wrecked upon the rock of puberty or adolescence;” in other words, a premature giving way of the nervous system, being inherently unable to stand the strain of life. Another suggestion is that it represents the outcome of abnormal types or reactions of the individual to the environment, with a failure of proper adjustment to surroundings and the formation consequently of mental problems which to the patient are incapable of solution. This may be called the psychological theory. The most commonly accepted idea, however, is the physical causation. According to this the disease results from auto-intoxication, the intoxicant arising from the disturbances of the glands with internal secretions, more particularly the sexual glands. This endocrine theory is supposed to be supported by the fact of the appearance of this disease most commonly at the time of puberty and shortly thereafter.

The osteopathic conception fits in very well with this latter view, inasmuch as the spinal lesions are quite capable of explaining not only a disturbance of innervation to the glands with the resultant interference in their normal secretion, but also could produce disorder of the circulation and nutrition to the brain.

=Symptomatology.=—Although each variety of Dementia Praecox has special symptoms characteristic of the type there are certain symptoms common to all forms, and these will be first considered. All the functions of the mind in the course of time tend to become disturbed and to be weakened, but in the earlier stages we find marked differences as regards the disturbance of different functions, thus memory and orientation in most cases seem good; on the contrary, attention and association of ideas somewhat poor. Emotional life is almost always markedly affected, even in the beginning. Very commonly at first there is depression to be followed later by expansive feelings and then by apathy in general. The will power is altered early and the conduct is apt to be peculiar. The judgment becomes impaired. All of these symptoms mentioned are deviations from the normal in the patient and therefore presuppose that the patient was formerly normal. This should sharply differentiate the praecox group from cases of defective development (imbecility or idiocy). In this latter group there is an arrest of development of the mind, whereas in praecox there is a loss in a developed intellect. We see a young patient, for example, who has lost interest in things about him, neglects his work at school or at home, remains alone for long periods of time and seems unwilling to mingle with other people. He gives the impression of one depressed and worried about something he is trying to solve, perhaps he mutters to himself or gives way to unprovoked laughter, he may refuse to eat, or to talk unless questioned and may even then not answer. When he does talk it will be discovered that he knows perfectly well where he is, and knows people around him and understands everything that is going on; his memory will be found good, he can usually recall past incidents and tell what he has been doing recently. As the condition progresses, however, while the patient may still for a long time retain fair orientation and memory for past events, his accumulation

of recent ideas will be found poor, so that he will recall them with difficulty. We notice that it is difficult to get the patient's attention and concentration seems to be impossible, he may answer a direct question, but immediately seems to be occupied with other thoughts and it takes some little effort to gain his attention again. If he continues to talk it is plain that the association of ideas is poor, giving rise to disconnected phrases which usually come forth sluggishly and without show of emotion. Dissociation of ideas occurs; that is, different ideas expressed may practically contradict themselves. For example, the patient may say he is a king and yet when asked to sweep the floor will do it perhaps without hesitation, not considering that is hardly the kind of work a king would do. The dissociation is also marked in the contradiction found between the content of the thought and its associated emotional idea, for example, the patient may speak of a near relative as dying recently, yet with no show of emotion, even with a meaningless laugh. This dissociation may ultimately result in complete incoherence, in which no sense can be found whatsoever in his speech. Emotional indifference is noticeable early and sluggishness of reactions to stimuli, even failure of such reactions; the patient will neglect himself, stay away from meals, express no desires and make no complaints. In the earlier stages, however, the patient who may have been for some little time apathetic, suddenly without apparent cause becomes angry, noisy, and possibly violent and destructive, again gradually relapsing into his quiet, apathetic state. The thought content is commonly associated with delusions, that is obviously false ideas, but which the patient is unable to perceive are false. Delusions of persecution are most common, the patient feeling in a dim way that everything is not right; and in attempting to explain to himself the reason, often attributes causes to people or forces outside of himself, and on account of the feeling of bodily discomfort, also by reason of the depression, he explains the external forces as unfriendly to himself. Hallucinations may be present and furnish the material around which the delusions form; on the other hand hallucinations may result from the delusions. By hallucination is meant a false sense perception, as the patient may state he sees someone before him who is not there, or that he hears voices from individuals who are not around him; he may also complain of receiving electrical shocks, or wireless messages, which he usually states come from his persecutors. Symptoms of this nature form a good example of the so-called split personality, or "schizophrenia," wherein certain idea complexes are split off from the main personality and address themselves to the main portion, the patient attributing these noises (voices), sensations (visceral and tactile), tastes and smells to an objective rather than a subjective source and subsequently forming delusions. However, unless we are dealing with the paranoid form the delusions are fragmentary, transient and absurd.

=Hebephrenia.=—This is a progressing mental enfeeblement, terminating usually in deterioration, and without showing marked peculiarities in thought or action aside from the progressing deficiency. The patient appears in general inactive, lacking in energy and ambition, indifferent, depressed, incapable of much concentration and hence the efficiency becomes progressively impaired until he is unable to accomplish anything. From time to time there may be periods of confusion, depression, passivity, at other times periods of excitement.

=Catatonia.=—In this form the general symptoms are similar to those of the simple type above described with the addition of the special symptoms referred to as catatonic excitement and catatonic stupor. The excitement period is manifested by an unrest and monotonous activity, stereotyped actions and speech, the patient constantly repeating some act, such as moving the hand, foot or head over and over again in the same way, or repeating the same word or phrase indefinitely. This occurs apparently involuntarily, the actions being automatic in character. The patient who has been in a semistuporous state may pick up a glass or chair and without show of emotion break it against the wall. In catatonic stupor the patient may show in the lighter degrees a simple loss of interest and feeling with sluggish reaction to stimuli, or a profound inactivity and stupor in which state he cannot apparently be reached by any stimuli; nevertheless, he apparently retains consciousness. In this type we observe the interesting symptom of negativism in which the patient always does the opposite of what he is requested, or refuses outright to obey any command. There may be a refusal of food so that the patient has to be fed by a tube, mutism may be present, the patient may go for weeks or months without saying a word; stereotype of attitude results in cataleptic poses and rigidity, in which the patient may maintain any particular pose for a prolonged period of time, and if placed in some other attitude may similarly retain the new attitude for a long time. This constitutes the so-called wax like rigidity, the patient reminding one of a wax figure. Pathologic suggestibility occurs in which the patient imitates movements, or repeats words and phrases that are spoken or performed before him.

=Paranoiac Form.=—In this type delusions predominate and are characterized by variability, inconsistency, illogicality and transitoriness on the one hand, with many gradations to the opposite extreme where they become more or less fixed, and often dovetail into each other forming apparently a systematic whole. They tend to be usually of a persecutory and hypochondriacal character and in later stages when the mind is distinctly weakened are often of a grandiose type. Sometimes the patients have some kind of explanations for them and at other times none whatsoever, and they are often curiously dissociated from the emotional accompaniment. The patient may state there is poison in his food, in an indifferent tone of voice or even with a laugh; he may claim that his teeth are all set in wrong and offer no explanations to these obviously false ideas. The patient commonly thinks

that somebody “has it in for him,” someone will do him mischief, will kill him, that people are talking about him and criticizing him, everything that he hears or reads he thinks has some bearing on himself, so-called “delusions of reference.” Hallucinations may be present, the patient hearing voices, or receiving impressions or ideas which he claims come from without. These external impressions he misinterprets as voices or forces which are accusing, threatening and slandering him. Later on, the patient tends to change from the depressed persecutory stage to an expansive one, when he claims he is some celebrated person, king or president, or pope. The impairment of the judgment is clearly demonstrated in these cases since the patient who may claim to be the king of England may beg the attendant to change his place at the table or for a postage stamp.

=Pathologic Anatomy.=—This is obscure. Since a certain proportion of cases recover, there can evidently be no degenerative changes at the outset, though some cases deteriorate fairly early, others only after several years. In some chronic cases there have been observed degenerative changes in the cortical cells.

=Diagnosis.=—First, the common age of onset during puberty and adolescence, fourteen to twenty-four in the vast majority of cases, this being the only common mental disease occurring during this age period. Second, the progressive character terminating in mental enfeeblement or deterioration, that is “dementia” proper. Third, the evidence of defect or deficiency symptoms indicating that the patient’s mind has altered in the sense of deterioration from its former normal condition, whereas, in imbeciles or idiots the mind has failed to develop in the first place. Fourth, in the earlier stages particularly the marked dissociation of the brain powers, some being well maintained as memory and orientation (that is knowledge of time and space), others being weakened, such as judgment, power of attention and the like. Fifth, the early appearance of the emotional defect, a remarkable indifference and apathy of the patient to people and surroundings, the patient being unsocial and taking no interest in anything. Sixth, all the peculiar motor reactions, which are mentioned above under the catatonic head, and which very rarely occur in any other mental disorder. Seventh, the delusional content nearly always refers to the patient’s exterior, forces outside of him, people or things which are exerting an unfavorable influence upon him, delusions of persecution and reference. The patient practically never accuses himself, as is the rule in cases of true melancholia, never blames himself, but always the other party or the other force outside of him. Eighth, the delusions of grandeur are usually indicative of a stage of deterioration.

=Prognosis.=—Some authorities are inclined to doubt if any case ever completely recovers, claiming that in apparent recovery it may have been a question of mistaken diagnosis, or that the recovery is more apparent than real, that the patient is not truly well, or will have a relapse, so that a permanent cure will be impossible. Other authorities admit the possibility of recovery though in a very small minority of cases. The statistics of the Still-Hildreth Sanatorium, covering more than two-hundred fifty cases show total recoveries of at least one-third. This includes all types and all stages of progress, many being advanced on entrance. Of the less advanced cases and those of not more than two or three years’ standing there have been some fifty per cent recovery. Many cases make improvement or become stationary in greatly improved condition, but are not included in the thirty per cent. Of the three types, the catatonic offers the best prognosis, the hebeprhenic the poorest, while the paranoiac occupies an intermediate position.

=Treatment.=—Of the etiologic factors above mentioned, that of auto-intoxication, resulting possibly from endocrine disturbances or other sources, is most generally accepted in the medical world and agrees excellently with the osteopathic point of view. Spinal lesions are regularly found more particularly in the dorsal region, which are quite capable of disturbing the innervation to the glands; therefore, their nutrition and activity. A correction of these before the disturbance has continued too long, and hence before deterioration has set in, should theoretically normalize the glandular condition and therefore prevent deterioration and enable the patient to recover. Such is the probable explanation of the results, and in many cases the recoveries were obtained in patients previously considered hopeless.

Remarks by Dr. Hildreth

In a great majority of the cases the cause lies in the interference between the fourth dorsal vertebra and the eighth, which analyzed means a disturbance of the great splanchnic nerves, through whose interference would be caused the toxic condition and even the sexual disturbance described in so many cases from standard authorities. The same lesion, if deep seated enough, could produce an interference with the vasomotors and reflexly interfere with the circulation to the brain. In many we also find a first, second or third cervical lesion. The effects of these lesions on the equilibrium of the circulation to the brain are easily traced through the superior cervical sympathetic ganglia. These lesions, namely, the mid-dorsal and upper cervical, especially when corrected in the earlier stages, have thus far proven to produce successful results. In a lesser number of cases we find the cause to be from the first to the fourth dorsal vertebræ; our reasoning here being that the interference or the physical disturbance must be so deep that it reaches and interferes with the deeper nerve currents, both downward and upward, thus disturbing the equilibrium of the circulation

to the brain. We have found this class to be the hardest to respond to treatment; however, that may be due to the fact that the physical defects at that point are harder to correct. Osteopathic treatment applied to the lesions above described without question offers therapeutics of intrinsic value to this class of patients.

Delirium, Confusion and Stupor

This clinical group has become well established, not only in its recognition from the dominant symptoms as indicated above, but also from rather definite causes. The immediate cause seems to be an abnormal blood state, or so-called toxemia, which may result from infectious diseases, or states of exhaustion, or autointoxications, or foreign poisons; the poison acts as an irritant to the brain. In states of exhaustion so-called “fatigue bodies” are formed and are apparently toxic in character. The autointoxicants may have various sources, such as chronic kidney disease, or diabetes, and the like. The most important of the foreign poisons are alcohol and morphine. This morbid group is further characterized not only by a toxic cause and dominant symptom complex of delirium, or confusion, or stupor, but by a similar onset and course. The onset is usually acute and the course somewhat wave like, gradually reaching a climax and subsiding, or resulting in death or becoming chronic. To emphasize the clinical symptoms of confusion which is so important the term “acute confusional insanity” has often been used, or “amentia,” according to the common German terminology. Hallucinations also play a prominent part, particularly those of vision; hence, another common appellation, “acute hallucinatory confusion.” Heredity is mentioned at most as creating a predisposition, though often the personal and family histories show no such evidence whatsoever. Intellectually there is a definite lack of orientation, the patient is unable to identify himself or his surroundings in time and space. He cannot clearly understand what goes on around him, that is, consciousness is “clouded;” the clouding may be of such extreme degree the patient’s mind becomes blank, due to complete psychic inhibition. This is referred to as stupor. The emotional life plays a secondary role subordinate to the intellectual content. The patient may be greatly excited for example, resulting from a frightful hallucination. The hallucinations are mainly of the visual type and are almost always present. The patient lives in a perpetual state of sense deception as if he were constantly dreaming; the hallucinations for the most part are of distressing, disagreeable or even frightful character. These may give rise to delusions, which are manifold, often fantastic and usually transitory.

Physical changes are always found associated with the disturbed mental status. If it arises during the active stage of an infectious process there is of course the high temperature and all other physical signs of fever. In a certain number of cases with temperature no definite signs can be found indicative of any of the well known fevers, hence has been called by various names, such as “Bell’s Delirium,” “Acute Mania Gravis,” or “Acute Febrile Delirium.” This ordinarily runs an acute rapid course with very high temperature, very marked delirium, followed by stupor and usually death from exhaustion. Even though no temperature be present the physical condition reminds one very much of that found in fever diseases. There is the lost appetite, resulting emaciation and malnutrition, insomnia, exhaustion, etc.

=Osteopathic Theory.=—While it may be admitted that the various factors mentioned above may take part as exciting or predisposing causes, it is obvious that in numerous instances mental disorders do not arise whatsoever, even when the patient is subjected to these factors. There must necessarily be other elements essential to produce the psychosis. The osteopathic theory comes in at this point to fill in and complete the chain of causes and to initiate the onset by the introduction of the idea of nutritional and circulatory disturbances resulting from the spinal lesions.

The records of the Still-Hildreth Institution show 18 of the toxic type, in which the poison is derived from without, who were treated, with 17 recoveries. There were 25 cases connected with the infection and exhaustion group, with 20 recoveries.

Remarks by Dr. Hildreth

In this group we have to do with blood disorders, resulting from the infections, conditions producing exhaustion, and the various toxins, or poisons, whether originating within the body or derived from without. These disorders are largely functional in character, resulting from brain irritation due to the toxemia or disturbance to the centers of nutrition. The main object of the osteopathic treatment, therefore, is to aid elimination and regulate and build up the nutrition. In most of the patients the physical lesions are found in the mid-dorsal area, chiefly from the 4th to the 7th, and in the cervical region, the 1st to the 3d. In aiding the kidneys in elimination the 10th and 11th dorsal vertebræ must be looked after. These conditions commonly respond very rapidly to the treatment and represent one of our most successful groups so far as results are concerned.

Manic Depressive Psychoses

The psychoses which are brought together under this classification include mental disorders which at first glance would appear to be of very wide variation, namely, conditions of maniacal excitement and those of depression. Further consideration, however, reveals the very evident reasons why they should be united as sub groups under the one head. The fact that these two mental states of seemingly opposite characteristics often appear alternately in the same individual, that in certain cases of each type there is a wave like feature in the nature of the attack and the frequency with which they tend to recur, together with other points of similarity in respect to duration, prognosis, etc., tend to point to their very close relationship. Kraepelin was the first to draw attention to these facts and advocate the present convenient and widely accepted classification of these disorders.

The outstanding feature is the disturbed emotional state which dominates and overshadows all other symptoms and is fundamentally the same whether expressed through the excitement of mania or the depression of melancholia.

=Etiology.=—Heredity is considered an important factor. Various authorities claim to have demonstrated direct hereditary influences in as many as eighty per cent and more of cases. Individual predisposition resolves itself into a matter of constitution and temperament in which there seems to be a greater tendency among those who are subject to the emotional extremes.

Early adult life is by far its most frequent period of onset, though it may arise also somewhat later. In certain cases the beginning of the disorder dates from some psychic or emotional shock. Just what importance these factors have as causes is little known since other cases develop in which the constitutional element alone seems responsible and no immediate exciting cause can be demonstrated.

The osteopathic viewpoint emphasizes the all important influence of spinal lesions as exciting factors. In individuals who have a tendency to this reaction their presence disturbing the cerebral circulation and nutrition may act as the direct causative factor.

=Manic Phase.=—The manifestation of this condition is brought about by the release of the inhibiting influences which normally govern all psychic function. Various terms as hypomania, acute mania, delirious mania, etc., have been used to differentiate the different degrees in which the symptoms appear.

In the milder types we find the following symptoms present. There is a marked feeling of well being. The patient, having lost sight of his personal limitations, feels a consequent exalted opinion of himself. His conduct is often rather boisterous, he talks a great deal, often swearing and using obscene language. He is inconsiderate of others and tries to impose his will upon those about him. There goes with this a certain unstability of the emotional tone as manifested by the quickly changing feeling of good humor, irritability and anger. There is a rapid flow of ideas with a marked loss in the ability to concentrate and direct thought. The ideas which pass through the mind do not coordinate themselves toward a definite goal, but deviate from the course of consecutive thinking by any passing association. Again there is a restlessness and activity beyond all normal bounds. The individual feels strong physically and mentally. The appetite is unusually good and if activity is not too extreme there may be a gain in weight. The period of sleep is diminished and the feeling of fatigue is reduced.

In the more exaggerated cases the flight of ideas becomes more marked, the associations are more rapid and superficial and the attention is focused but momentarily. Illusions and delusions may be present due to the imperfect preceptions from inability to concentrate attention and from abnormal associations. Rhyming speech, disconnection of phrases and even apparent incoherence are often present. The state of mind may be such that the patient tears his clothing, breaks up furniture, jumps, dances and shouts and often will not take time to eat. The most extreme cases which refuse food over some period of time progress rapidly to exhaustion and measures to conserve strength become imperative.

=Depressive Phase.=—In this phase of the disorder are encountered manifestations which are in direct contrast to those presented in the manic phase. In place of the exalted emotional state there is a depression. There is a tendency to worry over trivial matters of the daily routine and of instances in past life. Introspection is the predominant mental attitude and the whole outer world is colored by the inner feeling of worry and uncertainty. Replacing the rapidity of thought in the manic phase there is a distinct slowing of mental processes in the depressive phase. Thinking is more difficult and labored, questions are answered slowly and with an apparent effort and there is usually a tendency to avoid social life.

Again replacing the excessive activity in mania the depressions show a retarded action. There is disinclination or disability toward any effort either motor or mental. The patient feels weak and incapable of effort, the body assumes a bent attitude and the facial expression is one of despondency. The appetite is usually impaired with resultant loss of weight, the bowels are sluggish, the period of sleep reduced.

In the more exaggerated cases the retardation may be complete. Introspection is carried to the degree where the patient tries to take unto himself the responsibility for all the sin in the world. He himself is the arch sinner and he feels himself the subject of punishment by divine wrath in a manner in which no other individual was ever punished. Also the introspection tends to produce various hypochondriacal ideas. The patient may feel that he has contracted some incurable disease and that certain bodily functions have ceased operating.

Mental processes become not only retarded and difficult, but actually painful, a symptom which has been termed psychalgia. Suicidal tendencies are also quite frequently present.

In extreme conditions the patient may become so retarded in thought and activity that he apparently receives no stimulus from the outer world. He lives in a more or less stuporous state, even requiring that food be administered by tube.

=Circular Insanity and Mixed Forms.=—In addition to the conditions in which simply mania or melancholia are manifest there are certain cases which show variations and combinations of these forms. A common type is that in which there is an alternation of the manic and depressed conditions. The patient may pass directly from one state into the other, or there may be an intervening period of lucidity. The term circular insanity has been applied to this type. Other variations are those in which there are recurrences of the manic or depressive attacks often at more or less regular intervals, each recurrence being a practical repetition of the preceding.

There is also possible a considerable intermingling of the characteristics of the two types. In the manias may occur difficulty of thinking, passing feelings of depression and even almost stuporous conditions. In depressions there can exist a marked degree of restlessness and activity and a rapidity in the flow of ideas.

=Prognosis.=—The outlook for recovery from the individual attack is good. The attack may last from a period of days to one of a number of months and recovery comes with rarely any evidence of mental deterioration. There is a tendency to recurrence of the trouble. In fact recurrence is the rule rather than the exception. In the osteopathic handling of these cases it has been the endeavor to demonstrate that the correction of lesions had a tendency to lessen the duration of the individual attack and reduce the tendency to recurrence. Judging from the experience thus far gained in the observation of cases under treatment during the attack and the comparative few recurrences reported both of these aims have been attained.

=Treatment.=—The osteopathic measures are aimed at the correction of the spinal lesions, especially those located in the upper dorsal and the cervical regions. Some reflex effects from lesions in more remote areas may have their influence so that it is wise to look to the correction of any other structural variations when present.

Remarks by Dr. Hildreth

The mental disorders of this type are purely functional and may cover a broad scope as to causes; however, from the osteopathic viewpoint a great majority of them seem to have as their specific exciting cause, lesions in the upper dorsal and upper cervical regions. The treatment should be applied specifically to the cause which may range anywhere from the 1st to the 8th dorsal, or from the 1st to the 3d cervical, covering the nutritional and circulatory centers and thus controlling the nutrition and circulation to the brain. There can be no question but what the osteopathic theory of adjustment of physical defects forms the basis of permanent cure, since many of our recoveries had been previously under other methods of treatment without results. Our records cover over 200 cases with recovery in more than two-thirds, and very few recurrences up to the present.

Involutional Psychosis

In the mid years of life, between forty and sixty, a decline begins, which in the older years results in decay; it is especially true at this period of the sexual life and the organs underlying it. While these organs undergo a very definite change constituting the so-called climacteric period in women, it is not at first sight so evident in men; however, the evidence is that a somewhat similar process, though much slower, tends to occur in the male. Associated with the decay of the sexual organs is a disturbance presumably of the internal secretions; if this latter disturbance takes place slowly and evenly the body may not notice any marked changes; on the other hand, if it takes place more quickly, or unevenly, it may give rise to distinct symptoms which indicate a disturbance of the nervous system in general and often even of the mentality. Hence, the significance of the term, Involutional Psychosis. In a large majority of cases the mental disorder is marked by the dominance of depression and is frequently referred to as melancholia. For a long time it was considered that this represented a special mental disorder having little or nothing in common with other psychoses. In recent times Dumas has studied this group very carefully and shown that it in reality has very much in

common with the depressed phases of the Manic Depressive Group of psychoses. Kraepelin himself, who was the first to demonstrate the unity of the Manic Depressive Group, has accepted the conclusions of Dumas and incorporated the Involutional Depressions as a sub type of his Manic Depressive Psychosis. Among etiologic factors have been mentioned hereditary elements, which have been claimed to have been found in at least fifty per cent of all cases, forming presumably a predisposition; it is also stated that a predisposition may be acquired through various debilitating causes. Exciting factors are claimed to be present, such as mental shock, grief, worry and the like. The disease would then seem to occur when we have a combination of exciting factors and predisposition. Careful consideration will show, however, that no such mental disturbance occurs at this age in many people who show evidences of such predisposition and of exciting factors, therefore it would seem that still other causes were necessary; if we consider the suggestion above mentioned that there are atrophic processes taking place in the sexual glands leading to a loss of the internal secretions and if we further consider that this may take place unevenly and in an unbalanced way, thus aiding in giving rise to the symptoms, we will find a definite point of contact for the osteopathic conception. Osteopathically considered, we may say that the spinal lesions lead to a disturbance of innervation and nutrition to the ductless glands, and therefore produce disordered secretions in those patients developing the disease, whereas such a condition may not be present in others who at the same age period do not develop the psychosis.

Symptomatology

The emotional tone of depression dominates the picture. Associated symptoms are anxiety, fears, particularly of impending danger, the loss of interest in the external world, with a concentration of attention upon self; psychic distress is usually present, often to an extreme degree, leading apparently to real mental pain, so-called psychalgia. Delusions are usually present and manifold in variety; they mainly refer to the patient himself and are of a self-accusatory nature; they frequently refer to notions of sins having been committed, also unworthiness of the patient, of poverty, nihilistic ideas, either about his own body or external things. He may claim for example that he has no stomach or kidney, or heart, that the external world is unreal and the like. His motor reactions become retarded, or even in the more extreme cases inhibited, producing a form of stupor. The inefficiency which results along with the psychic pain and distress may determine suicidal tendencies which are very frequent. Orientation is usually good, the patient remaining aware of his own identity and that of his surroundings; the judgment of course is impaired so that the patient is unable to appreciate the unreality of his delusions; as a result he sees no hope in the future and on account of present sufferings prefers death to life. The patient may remain in a perfectly passive mood, giving the appearance of extreme depression, paying no attention to the surroundings, possibly mute, giving no regard to the necessity of the toilet, paying no attention to his clothing and the like. This may continue for hours or days. Food often has to be forced on him, possibly even by the tube; the result is usually more or less emaciation and may result in marked malnutrition; similarly the sleep may be seriously interfered with, even though the patient is quiet. The resulting loss of sleep and malnutrition sometimes lead to the death of the patient. On the other hand, the patient may moan and wring his hands in anguish, walking up and down, crying out that he is a sinner and that he wants to die and the like. This is the so-called melancholia agitata.

The physical symptoms of importance are sleep disturbances, poor appetite, with emaciation, cyanosis, often a subnormal temperature, low blood pressure, slowed heart action and weakened circulation. The hair may become gray, the skin dry and harsh and indeed any of the signs of senile decay may appear.

=Diagnosis and Prognosis.=—These depend partly upon the mental symptoms, partly upon the physical. On the mental side is to be emphasized marked depression, with the relatively clear orientation, resembling the depressed phase of Manic Depressive insanity; also the dominance of the self-accusatory delusions. On the physical side the age period, and the evidence of previous attacks, even though very slight. The prognosis from the study of the mental symptoms depends on the presence or absence of signs of defect, or deterioration, as for example foolish and silly delusions. On the physical side the presence or absence of conditions like kidney or arterial disease; in general, it may be said if the physical findings are negative and the mental symptoms show no deterioration there should be a good outlook, particularly if the condition has not become too chronic.

A favorable outlook is always possible if the disease is treated early and the lesions disturbing the activities of the glands and of nutrition and the circulation are corrected and if the other physical findings are negative and signs of deterioration absent.

Since this is probably only a sub-group of the Manic Depressive Psychoses, as has been mentioned above, the results obtained under osteopathic treatment are noted under the Manic Depressive group.

Remarks by Dr. Hildreth

Our experience with this class of cases invariably lead us to the nerve centers which regulate and control the process of nutrition and circulation; it is a matter of keeping up normal equilibrium of all organic life and especially the circulation to the brain. The basis of the treatment therefore is to be found in the nutritive centers, as well as those centers which control the circulation to the brain, the ductless glands, etc.

Senile Dementia

Senile Dementia may be defined as an abnormal weakening of the mind arising in old age. As the word dementia implies, the intellectual change is quantitative rather than qualitative, the prime characteristic of the disease being mental loss rather than mental perversion.

It is commonly stated that a most important cause of the disease is the general malnutrition incident to age. Since only a small proportion of the aged develop dementia, this is probably only a cooperating factor. Other causes mentioned are overwork, emotional strain, traumatisms, intoxications (especially alcoholism), cerebral arteriosclerosis and perhaps heredity.

=Pathologic Anatomy.=—The disease is organic, the brain exhibiting definite pathological tissue changes. There is an atrophy of many nerve cells and a proliferation of neuroglia fibers, so that the cerebrum becomes shrunken and hard, with thickened meninges and thinned cortex, and shows a loss of weight. The cerebral arteries may or may not exhibit sclerosis, thrombosis, or miliary aneurisms, with resultant areas of softening. The cells show pigmentary degeneration and many of the association fibers have disappeared.

=Onset.=—The onset of this dementia is usually very gradual, the condition not being recognized until rather marked. It occurs mainly in the seventies and later and in the late sixties, being rare before sixty. It often follows financial reverses, emotional shock, or various diseases. The earliest symptoms are a change in the person’s disposition, slight disorders of memory, and trivial lapses of various sorts.

As the disease progresses the symptoms become more marked and fundamental, involving not only the intellectual but also the emotional and volitional phases of consciousness. Interest in the outside world begins to flag, attention to wander, perception to be incomplete and inaccurate, association of ideas to be slow, memory to weaken and judgment to be impaired. Memory of the most recent incidents is the first to be lost, of recent years next, and then of middle age so that the patient may not recognize his own children or know, for example, that his wife is dead; finally the memory even of youth is lost and the patient is to all intents and purposes a child, his condition being an exaggeration and aggravation of that commonly known as “second childhood.”

Several forms of Senile Dementia exist, of which the most common is probably the simple or non-delusional type. Other forms are fundamentally the same as the simple, but with certain superimposed symptoms. Fairly early in this type it becomes unsafe for the patient to continue in business. Due to impairment of memory and judgment he is apt to lose his property. Soon his work is poorly done or neglected entirely. He becomes garrulous and annoys his associates with tiresome repetitions of childish reminiscences, continually wandering from one subject to another. His speech becomes incoherent and his sentences fragmentary. He grows untidy and indifferent to the ordinary niceties and conventions of life. His appetite is either poor or voracious; in the latter case the weight may keep up fairly well. He may be either apathetic or turbulent. If the former, he seems stupid, indifferent, and sleepy. He is credulous, docile, and very suggestible. Patients of the turbulent type are restless and always moving about, either depressed or elated, giving unreasonable orders and then contradicting them. Sleeping poorly, they are apt to get up and wander about the house at night. In men, prostatic disease may cause a recrudescence of sexual feeling. Patients of either type eventually become filthy, soiling their clothing, etc. Even in well advanced cases, however, senile dements are often able to perform well certain habitual activities, such as signing their names, or playing certain games, such as checkers or dominoes.

=Confusional Type.=—Another form of Senile Dementia, which may in severe cases usher in the attack, but which usually, when present, is sequent to the simple form, of which it is a more severe grade, is the confusional. The additional symptoms of this type are probably due to defective elimination and the consequent toxicity. Usually unsystematized delusions, and sometimes hallucinations are present. Except for a possible occasional period of remission the confusion is continuous. It varies greatly in degree, now being mild and passive and again active, perhaps developing into delirium. Orientation as to both time and place may be lacking. Such patients may ask for dinner a few minutes after a meal, go to bed at noon, be unable to find their own room, or to recognize their own children. They are apt to be obstinate and peevish. Delusions vary in type but both these and the hallucinations are usually painful and, being referred to the patient’s associates, give rise to the thought that they are trying to kill or otherwise

harm him.

=Delusional Type.=—A third type of Senile Dementia is the paranoid form. Dements of this type, owing to delusions of persecution and auditory hallucinations are sensitive and suspicious. Such cases may sometimes show good orientation, apparently unclouded minds, and little evidence of senility, requiring careful study to differentiate the condition from true paranoia. A patient may, on account of hallucinations of taste and smell, refuse food in the belief that it is poisoned. Members of his family who are devotedly caring for him are suspected of designs on his money, and this suspicious attitude frequently leads to unjust wills. The delusions and suspicions may be entirely concealed from the family. Wealthy paranoid elements are peculiarly apt to become the prey of scheming adventuresses, particularly in case of the above mentioned sexual recrudescence, and marry them. Opposition of the family is regarded as part of their general persecution or as due merely to their desire to get the estate. Some patients merely appear odd, suspicious, untidy, peevish, and childish. Some have expansive delusions and exhibit the euphoria so frequently found in syphilitic dements.

=Senile Delirium.=—A fourth type has been described by some psychiatrists under the title of senile delirium. This may appear as the initial form of the disease or as an acute attack in one of the above forms. It is characterized by great incoherence and restlessness, entire absence of orientation, and numerous rapidly changing delusions and hallucinations, the condition resembling delirium tremens. It is probably due to some somatic cause, such as nephritis, pneumonia, or cystitis, which is often fatal.

Complications may arise in Senile Dementia, such as apoplectic strokes, hemiplegia, epileptiform seizures and aphasias.

=Prognosis.=—It is evident from the pathology of the conditions that the prognosis is not at all good when the disease is well advanced. It is a chronic disease and usually progressive until death, which is due to one of the complications, malnutrition, or especially pneumonia. However, many cases have shown improvement, and in incipient stages recovery. A cure of advanced cases being impossible, the important consideration is prevention or arrest in its incipiency.

It is evident that this can be done only by preventing, or removing as far as possible, the predisposing causes. A glance at the list of these shows that much depends upon the cooperation of the patient by regulating his habits of life. Physical and mental overstrain must be avoided, deleterious habits, such as the use of intoxicants or narcotics given up. Much can be done by osteopathy to eliminate the effects of these upon the organism. Cardio-vascular and renal symptoms are very important and should be watched for in order that early treatment may check the process initiated. To this end the patient’s habits and diet must be regulated and treatment instituted to relieve toxicity and promote elimination. Lesions must be corrected, special attention being given to the lower dorsal that affect the kidneys, the upper dorsal that affect blood pressure, and both the upper cervical and upper dorsal that affect the blood supply and nutrition of the brain.

=Arteriosclerotic Dementia.=—This is a mental enfeeblement arising sometimes in the fourth, but chiefly in the fifth, decade of life, and associated with symptoms of arterial hardening.

The cause is arteriosclerosis, which may be secondary to some form of nephritis. The arterial hardening may be general or may be confined to the arteries of the cerebrum. It is likely that the arterioles supplying the cortical cells are especially involved in an atheromatous condition. The disease is organic, chronic and progressive. Hemorrhage, embolism, or thrombosis may occur, producing focal lesions and areas of softening, with hemiplegia, aphasia, etc.

The earliest symptoms may be headaches and dizziness. The blood pressure is usually found to be high but not invariably. An atheromatosis may be present in some one of the palpable peripheral arteries, such as the radials. Further symptoms on the physical side are quick fatigue, loss of energy, numbness and paresthesias of the extremities, and somnolence in the daytime or perhaps insomnia at night. Strokes may occur, usually slight and temporary, probably due to spasm in a degenerating artery or perhaps to serous effusion. Toxic symptoms appear, due to disorder in kidneys, liver, and other organs. Epileptiform seizures are possible. Mentally the patient shows impairment of memory, and perhaps some confusion and hallucinations. Rarely stupor occurs. He may be agitated and irritable or melancholy and depressed. Suspicious and persecutory ideas of the paranoid type may appear; also hypochondriacal ideas.

=Osteopathic Theory.=—In these psychoses of the older years of life the termination is usually dementia, which means mental enfeeblement, and which results from degenerative changes in the brain substance. As has been shown it is largely a nutritional question and the nutritional condition varies tremendously in different elderly people; it is well known that many old people preserve their brain powers fairly well to the end; on the other hand others fail relatively early, some even in the fifties; these cases of earlier

failure are referred to as the “presenile type.” The osteopathic conception would be to find out the source productive of the nutritional disorder and correct it at the very outset, therefore making it quite possible to prevent the disease process from taking place. The prognosis then in the earlier stages is very good.

Remarks by Dr. Hildreth

While many cooperating factors may be found in the causation of the mental disorder of elderly people, our experience shows there is always very definite disturbance of nutrition and the nutritional centers. We find chief physical interference between the 3d and 8th dorsal vertebræ, most definite as a rule at the 4th, 5th and 6th, with the corresponding ribs on the right side. Contributing causes may be found in other areas, associated with the disturbances of the heart and circulation and of the kidney. In the cardio circulatory disorders we find abnormal spinal conditions in the upper dorsal region and especially the 5th rib on the left side. In the kidney disorders we find the lesions usually at the 10th, 11th and 12th dorsal. The above mentioned areas in general represent the centers of control of the splanchnic nerves and therefore the important processes of digestion, metabolism and assimilation. Specific treatment applied to these points is very helpful and results in marked improvement and indeed in relieving the patient’s symptoms completely when in the earlier stages of the disease.

DEFECTIVE CHILDREN

By RAYMOND W. BAILEY

It is our purpose here to impress on osteopaths the almost unlimited possibilities in the study and treatment of mental conditions of children, which heretofore have been considered hopeless. Osteopathy has demonstrated that it has much to offer to this class of defectives but the profession has not thoroughly appreciated its great possibilities. It has been the custom to send these children to institutions where they have received care with some attempt toward education but with absolutely no effort being made through physical treatment to overcome their debility. We shall show that the osteopathic lesion is of prime importance in these cases, and that we have been slow to realize the efficacy of osteopathic treatment for such seemingly hopeless children. We cannot emphasize too strongly the importance of accepting and treating these cases wherever possible.

The mental diseases are considered under two general heads: (1) Inherited, and (2) Acquired Tendencies.

=1. Inherited Tendencies.=—In this class are those cases arising from poor endowment of the protoplasmic structure through lowered vitality of the parents or other progenitors. These taints may come from either parent, or both, and may exist in the offspring from some preceding generation. Such diseases are constitutional and are amenable to supporting treatment in direct proportion to the amount of endowed energy inherent in any given organism.

Of the inherited tendencies, we have two kinds:

=1. Congenital Diseases.= (a) From any influence of an inherited nature not directly acting on the environment of the parent while the fetus is in utero, and

(b) From any influence which directly affects the development of the ovum through imperfect fertilization coming through either parent or both.

=2. General Impairment.=—This condition exists (a) Where a similar defect has existed in foregoing generations and is strictly hereditary;

(b) Where general vitality is diminished from such causes as neuropathic parents, or where there have existed constitutional defects, such as tuberculosis, syphilis, epilepsy, alcoholism, abuse, overwork, strain, acute inflammatory diseases, and poor health of the mother during gestation; also consanguinity.

(c) Premature birth tends to impairment physically and mentally of growth of organism and frequently leaves its manifestations of marasmus, rachitis and other nutritional disturbances.

(d) Prolonged labor may leave its mark on the child where more or less asphyxia has occurred resulting in obstruction to cerebral circulation.

Causes acting after birth to the already impaired germ cell and resulting in many of the afflictions of early life, both mentally and physically, are

1. Traumatism. 2. Convulsions. 3. Rachitis. 4. Infectious fevers. 5. Meningitis.

All of these seriously affect the metabolism within the newly-born, a process which is begun, doubtless with difficulty, and susceptible to easy derangement, and the same effect magnified with growth into its subsequent mental and physical deformity.

=2. The Acquired Tendency.=—In this the second great class are those conditions arising subsequent to conception where germ plasm is healthy but growth is arrested by some external factor either intra- or extra-uterine. Thus the acquired tendency may be given to the fetus in utero and not be considered congenital as in case of injury affecting health and growth of otherwise healthy conception. In short, the acquired has its beginning at conception or subsequent to it while the congenital is previous to conception or already inherent in the germ plasm leading to conception.

Any influence which retards the

1. Inherent capacity of cell for growth or,

2. Adequate blood supply either in quantity or quality results in enfeebled offspring and these causes are enhanced by

(a) Traumatism or Injury (b) Drink or Abuse (c) Dirt or Unhygienic surroundings (d) Depravity or Ignorance

Factors entering into acquired tendencies affecting offspring direct are divided into three classes, those:

I. Before Birth such as

(a) Abnormal condition of mother’s health during pregnancy as in disease of any nature, mental or physical or

(b) Injury to fetus direct by blow, fall of parent, or instrument.

II. During Birth from:

(a) Abnormal labor from any cause.

(b) Primogeniture.

(c) Premature birth.

III. After Birth.

(a) Traumatism.

(b) Toxic causes such as scarlet fever, whooping cough, meningitis, measles, mumps and exanthemata.

(c) Convulsions.

(d) Nutritional disturbances.

Consanguinity or intermarrying of blood relations, or in-breeding results in:

1. Instability of the nervous system.

2. Intensifying of constitutional defects.

3. Decrease in size of offspring.

4. Predisposition to disease through lowered vitality.

5. Impairment of reproductive function.

Immediate consanguinous offspring may manifest a high degree of intellectual or physical attainment but successive processes tend to neurotic types and are prone to physical weaknesses and insanity. This practice is found among Quakers and Jewish peoples, inhabitants of the Islands north of Scotland, in isolated rural localities, and among African tribes.

Mental Deficiency in Children

=Synonyms.=—Amentia; feeble-mindedness.

There are three grades of amentia:

=1. Morons:= those whose mental age corresponds closely to their chronological age or is nearly normal.

=2. Imbeciles:= those in whom there is a wide disparity between the mental age and the chronological age.

=3. Idiots:= the lowest form of arrested mentality or those whom it is impossible to teach.

=Definition.=—Mental deficiency is a pathological stage in which the mind has failed to attain normal development.

=Various degrees of intelligence= or mental capacity in man lie between:

(=1=) =Genius= such as Bacon, Newton, Plato, Galileo, Shakespeare.

(=2=) =Lesser Ability= but still conspicuous in development such as our great leaders in science, literature, reform and the arts and medicine, furthering, each their respective causes. These merge easily into

(=3=) =Average= mass of mankind.

(=4=) =Dullards= or those of inferior intelligence.

(=5=) =Feeble minded=, merging imperceptibly into

(=6=) =Imbeciles= and by insensible gradation into

(=7=) =Idiots= and gross idiots.

The mentally defective is wholly incapable at maturity of adapting himself to his environment or local conditions in order to maintain existence independent of any external support.

=Dementia= is a disease of the mind or that which was once possessed, and by some neuronic disturbance is lost totally or partially.

=Insanity= is a disturbance of neuronic function which may or may not end in degeneration of brain tissue.

=Physiology.=—The normal brain begins its development shortly after fertilization of the germ cell, by the expansion of the anterior end of the rudimentary spinal cord into four primary cerebral vesicles. These develop into a series of elaborate infoldings, each with multiple cells around them. At or about the sixth month of fetal life this embryonic brain assumes the shape of the adult brain, minus the secondary fissures and convolutions which are characteristic of full development.

At birth there are sometimes many convolutions and the brain weighs from 280 to 330 grams. Growth is then rapid and at six months it weighs from 560 to 680 grams;

At one year, 750 grams. It continues to increase until

At 12 to 14 years it weighs 1150 grams in the female, and 1300 in the male;

At 20 to 21 years the weight is 1244 grams in the female and 1374 in the male.

Growth is slow from this time until at 25 to 35 years the average weight of the brain is 1269 grams (45 oz.) in the female, 1421 grams (50 oz.) in the male.

This growth of the brain is due, first to the rapid multiplication of nerve cells and, secondly, to the individual enlargement of each nerve cell. These cells arise from the floor of the four primary vesicles and are each similar to its fellow. They finally show differences in feature and become characteristic in size and shape which process continues throughout life. This process of differentiation of nerve cells results in the peculiar laminated appearance of the brain cortex. At the period of lamination, the nerve cells throw out delicate processes which pursue definite directions throughout the brain mass constituting a system of association fibers which link together in a most complicated manner all parts of the brain, and are called the association fibers of Flechsig.

Projections from these cells form the various pathways by which the brain is connected to the various parts of the body.

Nerve cells in the different parts of the brain mature at different periods, those areas which have to do with the highest intellectual functions, viz., the frontal and parietal regions, maturing last.

At the seventh month of intrauterine life the brain cell is a small round type of neuroblast, undifferentiated, lying in a matrix. The cells increase in size until about the second week (extra-uterine) of life, tiny processes begin to develop. At the third to fifth year these cells are mature and possess axons, dendrons and geminules. These communicate, forming the above named association system conveying impulses to and from all parts of the cerebrospinal system. They multiply and elaborate after puberty into a complicated system up into middle life after which growth ceases and they slowly diminish.

=Greatest Growth= is between the first appearance of the primitive brain and the end of the sixth month of life (extra-uterine), hence it is during this period that any adverse conditions relative to development of nerve cells may cause the greatest damage.

=Mind and Brain.=—Whatever may be the connection between these two, we know that the former develops with the growth of brain cells and fails with their decay. =Amentia= is associated with the incomplete development of brain cells and =Dementia= is coincident with their degeneration and death.

=Pathology=—=Brain.=—Structural abnormality of the brain tissue may exist without variation of mentality or defect. Early observers gave these gross defects as a cause for amentia. However, it has been demonstrated beyond doubt by microscopic examination of cerebral neurosis that cellular changes occur and that imperfect and arrested development exists and is an essential basis of amentia.

=Histology=—=Blood Cells.=—Cortical blood cells in the ament are

1. Numerically fewer.

2. Irregular in arrangement.

3. Imperfectly developed.

4. Microscope reveals changes proportionate to the deficiency during life.

=Blood-vessels in Amentia= show no marked changes from those of the normal brain. Hyaline degeneration may be present; also pigmentation. These conditions are not constant in amentia hence cannot be considered causal.

=Neuroglia in Amentia.=—Sclerosis and hypertrophy occur in a large proportion of cases. This is diffuse throughout the brain, with here and there certain circumscribed areas forming nodules.

=Nerve Fibres of Cortex in Amentia.=—Association system fibres are always diminished in number and not so complicated.

=Clinical Varieties of Amentia.=—There are two varieties of amentia and conventionally for sake of study we must arrange them into those from

(1) Congenital causes and (2) acquired causes.

Among those which arise from congenital causes we have the microcephalous and Mongolian types. In both cases there exist constitutional taints through successive or immediately forgoing generations of such diseases as syphilis, tuberculosis, epilepsy, and acute alcoholism affecting proper collaboration of germ cells previous to fertilization and hence impaired germinal endowment through a weakened nervous system.

Those arising from acquired causes are from injury to mother or fetus.

=Macrocephalus.=—A person whose skull measures less than seventeen inches in its greatest circumference. This class comprises less than 10% of all aments.

=Cause.=—The type is neither a freak reversion of the species to a lower grade of development nor accidental, but due to an inherited blight on the nervous system arising from constitutional disease, alcoholic and sexual excesses, consanguinous unions and too numerous latter-life pregnancies in undermined health states. They come entirely from neuropathic stock and their brothers and sisters are degenerates. Many dwarfs exhibit this type.

=Characteristics of Microcephaly.=—(1) Circumference of skull diminished; (2) Brain smaller; (3) Stature small (5 feet); (4) Rarely live to advanced age; (5) Die of tuberculosis; (6) Mostly imbeciles and idiots (few morons).

They have their sensory impressions intact and are generally vivacious and muscularly active, even restless. They have good sight and hearing and are highly initiative but have not the ability to any sustained effort. They are actively observant and the majority are affectionate and well behaved. Some are unsteady in walking, others are helpless, and about one-half are subject to epileptic fits.

=Mongolian Amentia= (Mongolism).—This type (Kalunk or Tartar variety) received its name from Dr. J. Langdon Down from their facial resemblance to members of the Mongolian race. They number about 5% of all aments including the semi-mongols who have only a few of the characteristics of this type.

=Cause.=—Eleven out of twenty-five are from syphilitic origin. Glandular or nutritional defects are suggested as a cause. They will show negative Wassermann test and positive tuberculin tests. Uterine exhaustion and ill health of mother during gestation are factors suspected of entering into this condition. The latter-born of large families are frequently affected.

=Pathology of Mongolian Idiocy.=—The brain of the Mongolian ament is considerably under-sized and has less convolutions and is more shallow. The pons, medulla, and cerebellum are about half the size of ordinary feeble minded types. The cells by microscopic examination show an immature condition. This lack of brain development results in deficient expansion of base of skull, hence the characteristic physiognomy. There is no glandular abnormality.

=Description of the Mongol Type.=—This type is distinguished by characteristics of skull, eyes and tongue and is usually observed at birth.

1. The skull (Brachycephalous) is rounded and diminished in size particularly through the antero-posterior diameter. The face is flattened, there being no recession of frontal and supra-occipital regions.

=Eyes.=—The palpebral fissures are narrow and slope obliquely downward and inward. Lids inflamed.

=Tongue= protrudes, is large and marked by large papillæ and scored by transverse fissures due probably to tongue sucking, predisposing to inflammation of the mucous membranes.

=Ears= are small and round and have poorly developed and irregular lobules.

=Nose= is short and flat and has triangular nostrils.

=Teeth= are soft and ill formed and tend to decay.

=Hair= is usually scanty and wiry and very dry.

=Cheeks= are flushed. Palate is high and narrow and mouth is open, and lips are cracked. Adenoids exist in all cases.

=Hands and Feet= are broad and clumsy. Flat foot and knock-knees are common. Skin is rough, coarse and dry.

=Abdomen= is large and mushy. Umbilical hernia often present.

=Circulation= is rarely good, causing blueness and coldness of extremities, with sores and chilblains. Heart lesions are frequent. Lesions of a chronic inflammatory nature in respiratory and digestive tracts exist. Nasal and bronchial catarrh and diarrhea are common. Mongols die early (about 14 years) usually of phthisis.

Available statistics show the various types and variations of these conditions in great detail; however, the above will enable the reader to classify and properly diagnose in given cases. It is not the writer's intention to portray here what is easily a treatise by itself.

=Osteopathic Consideration of Amentia.=—During a period of five years, observation of the various types has led me to believe that much can be done to correct circulation to cerebral structure with consequent development of brain tissue and function, where discoverable trauma exists. From all available sources there is traumatic interference in from 15 to 45% of these cases, according to different authors. Where history involves constitutional findings (syphilis, tubercular, glandular and chronic alcoholism) I have treated them with the intent of relieving only until the next phase of the condition would appear. Where trauma alone exists and the family history is good, I know the case is in the field of osteopathy alone, and can be developed to a degree limited only by the

intelligent care of those having the case in charge. Especial attention should be given to discipline, housing, sanitation, personal hygiene and general environment.

=Lesions.=—Atlas, generally rotated. Rarely posterior but frequently resting beneath a posterior occiput. Lateral mass on the posteriorly resting portion of misplaced atlas will become interlocked with transverse process of axis in a few instances, combining the amentia with a progressive inflammatory tendency to the middle ear which by successive abscesses ultimately destroys structure and function; possibly traumatic epilepsy, and surely catarrhal inflammations in all mucous membranes of the head.

Many bony and ligamentous irregularities exist in the various types of mental defective where the cause is inherited weakness, nutritional diseases or kindred sources. Spinal luxations exist singly and in series, causing various palsies, spastic muscles, and deformity. Postural defects, particularly of ribs and costal cartilages cause functional disturbance throughout the thorax and abdomen.

=Treatment.=—Invariably the care of aments entails wisdom of procedure. Reconstruction is the prime object in every instance, hence time and number of treatments must not be considered. Treat to =correct structure; teach= as far as possible; =train= always.

Deft and intelligently applied technique are certainly required in the correction of these cervical lesions. Treatment should be given thrice weekly (never less than twice for progress) with definitely established mental tests before, to discern the mental level, and at succeeding periods of three months each, noting progress, if any. The Binet-Simon scale or some other available mental test should always be made and record carefully kept of each case for your own benefit as well as the patient's. After six months, if no appreciable gain is shown treatment is discontinued and the case must be cared for in another manner as beyond your special field of effort. Usually it is apparent by the end of the third month if anything can be done to improve the mentality. The physical advantages, in some cases warrant continued treatment where there is no appreciable mental gain. Institutional care of these types is the only practical means of handling them properly from an osteopathic standpoint, as it requires some one properly equipped to make your tests and keep your record;—it is sufficient for the doctor to do the work demanded. They can thus be classified and progress systematically shown. The higher grades must be taught and though self dependence may never be attained they can in many cases by training be capable of useful pursuits and quite frequently remunerative work. It makes for happiness at least to keep them busy and forestalls the mischief that would otherwise result. Even imbeciles can help in routine work of an institution or home, and idiots may, by training, gain some power of self help and cleanliness. Training depends on the individual capacity for such in each case—his habits, and general character of his propensities. Prevention of their marriage should be positive and for prevention of their propagation this and their sterilization by operation are the only two measures at hand. Sterilization, however, is repugnant to some elements of society and could be abused, hence the segregation of aments would appear to be our only solution at present. The ultimate intention of treating any case is to use any measure tending to stabilize the nervous system. Corrective effort alone is not sufficient but these osteopathic endeavors in conjunction with proper discipline, good food, regular rest and personal hygiene both mental and physical and a scrutinizing restriction tending to any kind of excess is rendering the osteopathic procedure in such cases rapidly indispensable for the treatment of amentia.

POST-OPERATIVE TREATMENT

By GEORGE A. STILL

At the convention of the American Osteopathic Association held in Boston in 1918, I gave a short talk on the above subject, and during the day after I had given the lecture, two women and one man, graduate osteopaths, asked me if I really meant to convey the impression that we actually gave osteopathic treatments to recent surgical cases. I do not know whether I convinced them or not, but I do know that they convinced me that there are people practicing osteopathy who have absolutely no concept of its merits and underlying principles.

To my surprise I have found that a great many osteopaths who consider themselves absolutely "pure" are just a bit startled at the thought of handling post-operative complications by treatment. These are invariably fellows who have had most of their experience in office work, and who do not come in contact with acute cases. Still it is difficult to conceive how a man can believe that osteopathy is specific for certain diseased conditions and not for others. As a matter of fact osteopathic treatment has not proved itself more satisfactory in any field of therapeutics than it has in post-operative conditions.

The common post-operative conditions are pneumonia, pleurisy, backache and headache, nephritis, vomiting, neuritis, phlebitis.

Taking up these subjects and discussing the least serious first we would of necessity discuss pneumonia last, as it is the most serious, and is less influenced by other conditions. It will also serve to illustrate many of the details in treatment.

We will therefore briefly take up the other conditions and then discuss pneumonia more fully.

Vomiting

We believe there is no question that a good part of the prevention of anesthetic vomiting is in the preparation of the patient, including a good cleaning out of the bowels without debilitating cathartics. In other words, the vomiting is increased if the alimentary tract is loaded, or if on the other hand it has been irritated to the extent of losing its tone. Combining a careful preparation with a straight ether anesthesia and osteopathic treatment to the neck and splanchnics we have been able to eliminate any serious post-operative nausea. I do not recall a case in the last few years that vomited on the following day unless the condition for which they were operated was one that essentially in itself would cause vomiting; for instance if the patient had peritonitis and had been vomiting due to the toxic ileus. They might even vomit after the abdomen had been opened. This could hardly be called "post-operative" vomiting.

The improvement in our records in post-operative vomiting is in proportion to our increased faith and use of the osteopathic treatment. Time and again patients have told us that they had taken anesthetics before and were sick from three to five days and even a week. Invariably we have been able to surprise these patients by the fact that they were sick less than a day.

The usual treatment with bismuth sub-nitrate, cerium oxylate, sour wine and the other usual remedies were not used in any case or in any amount. No drugs whatever were employed.

Backache and Headache

There is practically no difference in the post-operative headache and the office headache. There is of course the usual multiplicity of causes, and as a matter of fact in this condition treatment can more nearly approach the ordinary office treatment, and the results are about the same. As for backache, we find that speed of operating and not keeping the patient under the ether too long has a marked influence. Also we have a four inch Seely mattress on the operating table which helps some. Treatment does the rest and does it effectively. For this complication even the ordinary nurse knows enough to give a treatment of some sort.

Neuritis

Nine times out of ten the post-operative neuritis is really a local osseous lesion, a slipped innominate, rib, vertebra, clavicle, biceps tendon or something of the sort, and responds quickly to a specific treatment.

Phlebitis

This complication usually comes on quite late after an operation and at first it is sometimes hard to differentiate it from a neuritis. Absolute rest of the involved part with lower spinal treatment gives relief, but under no circumstances should the affected part be freely moved while there is active inflammation. The reason for treatment of the lower spinal area is that practically always one of the saphenous veins is involved.

Nephritis

This complication is to a very big extent eliminated by a careful urinalysis prior to the operation, and careful preliminary treatment in indicated cases, and in other cases the postponement or if necessary complete elimination of the operation where it is not a case of life and death. Where the condition does appear we have found it the hardest of the post-operative complications to control. Indeed it is the only one that we have not found very easy to manage.

We do not vary the treatment for a post-operative nephritis from what we would use in any ordinary case of nephritis. We have observed treatment of this condition in many cases under medical management, and while we are satisfied with the osteopathic treatment comparatively we are not yet satisfied that we have it developed to its greatest efficiency.

Pleurisy

This condition in nearly every instance can be corrected with one or two treatments of a twisted rib unless it is the pleurisy of a beginning pneumonia. As far as the pain is concerned the simpler type hurts as much as the one that is going to develop a real complication. For this reason relief obtained by a single treatment often seems little short of miraculous to the patient.

Pneumonia

When I took charge of the surgical work at Kirksville, osteopathy was not used in post-surgical treatment. Post-operative vomiting was treated medically, as were other post-operative conditions, including pneumonia. Cases of a real major surgical nature rarely got an osteopathic treatment.

The idea seemed to be that osteopathic post-operative treatment had to be along the same lines as it would be for such an illness as lumbago, brachial neuritis, or ordinary pneumonia, and other non-surgical conditions where the patient could be placed for giving a treatment in a position that was not permissible following an operation, as it would work great harm to the wound.

It seemed to me that if osteopathy was effective in a case of ordinary non-surgical pneumonia, it should certainly be good for a case of pneumonia that was post-operative and that all we had to do to handle the condition was to apply a new technique of treatment that could be used on a patient who had a surgical wound. All we had to do was to so manipulate the spine that we would get the results locally, and yet handle it in such a manner as not to affect the wound.

Many laymen, and even some physicians of our own school, express surprise at the suggestion that we do much osteopathic work in the after care of surgical patients. But the fact is we have worked it out so that now, except for pain, during the immediate after effects of the operation drugs are absolutely not used in our hospital for any of the post-operative complications. The opiate immediately following the operation, is really a follow up of the anesthetic, and we use that as rarely as possible. Needless to say, there are cases such as un-united fractures, extensive adhesions, etc., where the emergency conditions positively call for some relief of the pain for a short while, but that is the only condition that we cannot control with mechanical treatment.

I am very glad that I had the confidence to give this an early trial and a thorough trial, without being afraid to leave off the drugs. The big field, however, where osteopathic treatment has won the most impressive success and proved itself a most absolute specific, is in the field of post-operative pneumonia with which I am proud to announce a one hundred per cent. success for combined osteopathic treatment in my fourteen years continuous surgical work. Not to have lost a single case is partly due to luck. In other words, with any series of serious cases, it is impossible but that there be some fatality finally.

Post-operative cases have one advantage along with their disadvantage. While they have the shock of the operation to contend with, and the weakened condition from the disease for which they were operated, still except in extreme emergency they would not have been operated on unless they had a good heart and good kidneys and a good blood pressure, so that in cases in which we are most concerned in combatting pneumonia, we usually start with a patient who has those organs in a healthy condition.

=First Post-operative Pneumonia Cases Treated Osteopathically.=—At the Chicago Convention in 1911, I reported the first post-operative pneumonia cases that had been treated osteopathically. I believe at that time that there had been only three cases. At that meeting I mentioned the fact that some of the doctors and some of the internes who treated those cases felt sure that they were not treating them properly because they could not get away from the idea that pneumonia needed strychnin and other drugs. One of these cases got well in three days from the developed lobar pneumonia symptoms. The results were so miraculous that the young man treating it began to doubt whether it could have been pneumonia. He could not understand how he, a senior student, could overcome this dreaded disease by merely working on the spine. He could not believe that osteopathy, a science that he had been able to learn himself, so easily could cure a condition that he had thought must be almost necessarily fatal.

One of the weaknesses of osteopathy is the fact that there is no mysticism about it. It is so simple that any person with ordinary intelligence can learn to use it, and yet it is so simple that it takes an unusual intelligence to be able to grasp the fact that it is the therapeutic discovery of the age. Many, many times I have had young internes and students cure genuine lobar pneumonia and do it with such obvious ease that it caused them to wonder, in a way, if it really could be pneumonia. It is bred in our very tissues to look for some mysticism, something impossible to understand, something supernatural, something connected with the Unknown associated with the treatment of disease and accordingly it is just human nature to find it difficult to believe, even when we see it, that a simple method of treatment can actually effect a cure.

Real pneumonia, as we understand it, is a consolidation of the lung tissues characterized by fibrosanguinous exudate into the pulmonary tissues and spaces, associated with one or more particular germs as exciting factors and proved by the physical tests

and the character of the expectoration. How many cases have been cured that had not entered consolidation I do not know because up until the time of actual consolidation there may be a question as to whether or not they would have had pneumonia. I know that many cases with marked symptoms of pneumonia have failed to develop under treatment or the case has been aborted.

Pneumonia lacks a great deal of being a self limited disease. The number of cases with beginning symptoms that fail to develop is too great to be ascribed to coincidence. Of course I know that some of these might have been only pleuritis, some only neuritis, etc. However, in giving the statistics of pneumonia cures we will give only those in which pneumonia developed and showed a hardening or consolidation of the lung tissue. In these cases there can be no argument as to whether there was pneumonia.

When we have an acute condition associated with the symptoms of consolidation, we can hardly be confused as to the diagnosis. We may make a mistake in our physical findings, but hardly after a little experience, and certainly when we are sure of the physical findings there will be no trouble in naming the disease.

=The Clinical Findings.=—Post-operative pneumonia is a little different from the common pneumonia. It always comes on a little more insidiously. One has to watch for post-operative pneumonia more closely than he would for the attack that we may meet in ordinary practice. A patient may have considerable pain from his wound, may have some pain in the back from the position he is in; there may be headache, and an upset feeling from ether; and the pain comes in the chest. All these symptoms are forerunners of pneumonia, but the pain in the chest is not noticed until it gets quite severe. In other words, there are other things to annoy the patient as well as the attendant, and at first, this condition does not cause complaint. A strong and healthy individual who feels a pain in his pleura, which is the forerunner of pneumonia, knows it at once, because that is the only distress he has. His entire attention is attracted and he asks for a physician's help. But in the post-operative case, the physician has to keep a look out in order to prevent a case from getting well under way before it is recognized.

As an example of this I had a case of a man who was with a party driving an automobile and they tried to cross the railroad track in front of a train. This patient I speak of was one of the survivors. He had a fracture of the femur, fracture of the skull, fracture of three ribs, and otherwise more or less bruised up. Naturally the preliminary work consisted in getting the ribs and legs attended to as well as possible and looking out for cerebral hemorrhage or meningitis.

This patient developed consolidation in both lungs in spite of regular treatment, and it precipitated on him very rapidly, partly masked by the disturbed breathing from other sources of irritation. We put him on hourly treatment, but after a few hours his condition from the injuries and the pneumonia was such that his wife asked us not to treat him any more. She put it this way, that she knew he would die in spite of all that could be done and as long as he was going to die he might as well die easy. Every time he was treated it had the effect of bringing him out of his stupor, and he would complain, and she thought it would be a kind act to let him slide off into the next world uncomplaining.

Pneumonia in a case of this sort cannot be handled with kid gloves if we wish to save the patient. We must give firm, strong treatment. Light treatment in this condition will do no good. Indeed light treatments in any sort of pneumonia are of little avail. Many times I have changed internes in a pneumonic case that was not responding and the results were immediate. That is, the turn for the better was obvious from the beginning of the good strong treatment.

The case above mentioned was treated a good part of each hour for twelve hours. He had no strychnin, no oxygen, nothing but treatments, but he got well and is now living, and aside from a limp has no evidence of either his injury or his illness.

Some cases, in private practice, may get well on a treatment a day, but I would hate to handle the kind of cases we get in that manner. I have had severe cases, especially hemorrhagic cases, where the treatment was almost continuous for hours preceding the crisis. Of course, after the crisis we can ease up. On the other hand, it is not infrequent that a few good strong early treatments, given at the beginning of a case absolutely stop it. I have seen cases where a consolidation area of the apex of the lower right lobe as large as the palm was easily outlined, and this together with the clinical symptoms would be cleared up in two or three days.

There is no possible medical method by which this can be done. Medical authorities agree that under their treatment pneumonia runs an unshortened course; in other words, a course in the individual case that has not been affected by the medication. Medically, even where the crisis occurs early, the consolidation persists for some time, but I have seen it cleared up time and again under osteopathic treatment in the length of time that could have been brought about only by osteopathic treatment.

I have previously called attention to the fact that many of the medical text books on physical diagnosis mention a point that is a very practical and very plain demonstration of the efficiency of osteopathy in pulmonary conditions. These books only mention this fact

without pointing any moral or drawing any conclusions. The point is this: that frequently when a professor is having a class or a section of a class examining a case of pneumonia, they will outline the size of the consolidation at the beginning, the instructor marking it off when he makes the first examination; then after the students have examined it, by percussion, palpation, etc., possibly a dozen or twenty of them, the later students will find that the area has shrunken perhaps an inch. This fact has been frequently noted. It is said, indeed, that if careful examination is made it will always be noted.

How Manipulative Treatment Benefits

Doubtless this proved that accidental manipulations of the ribs helps clear up the congestion about the real consolidation and reduces some of the dull area. Very likely this explains some of the cases of partial or real results from spondylotherapy. Naturally, scientific osteopathic treatment would necessarily magnify such results very much.

It is a great wonder with the obvious failure of medical treatment in pneumonia, that at least some crude from of manipulative treatment has not been devised by those practitioners. We have already mentioned that the treatment of post-operative cases varies mainly in the manner of applying it. In other words, when we raise the ribs we keep the patient on his back, in treating the spinal centers we treat with patient on his back, and the physician who has no grip in his hands will not be able to treat a post-operative pneumonia to any advantage.

In these cases one has to get at the patient's back by reaching under and the weight of the patient helps to give the treatment, but a strong grip is necessary. It is much safer for the wound to handle the patient in this way but not infrequently beginners wear their knuckles pretty nearly off before they get the finer technique; after which it is easy. In raising the ribs there is no more difficulty in treating in this position than there is with a patient who can sit up or turn from side to side and in some cases a patient can, of course, be partially turned.

Theory is all right but in these cases practice has been added to it in something over three hundred cases treated in this manner, and in this manner only. I have had no case die. None of my cases had oxygen and none of them had strychnin or alcohol unless it was a person who had used alcohol constantly or daily and in these cases I consider that the system has become sufficiently used to it that it is practically a food and that sudden withdrawal is apt to bring on delirium. It is not necessary in those cases that indulge deeply now and then, but it is advisable in those that take a small amount regularly, just as they take food. These patients are used to a constant heart stimulant and its withdrawal is also apt to be reflected in the heart action. These are the only cases in which I have ever authorized anything in the way of a chemical stimulant of the heart during pneumonia.

You will undoubtedly recall that in reading the newspaper accounts of men who are big enough and prominent enough to have bulletins in the newspapers when they are dying, that almost universally the next to the last bulletin was that oxygen is being administered. The last bulletin announces the time of death. You will also note that in case the patient lives that oxygen then is not mentioned, and a few days later the patient is all right. My observation is that the use of oxygen may attract the attention of the family, it may attract the attention of the patient, but as for any actual benefit on the patient I do not believe it is in the least helpful, and that the only treatment for pneumonia is osteopathic. I am so convinced of it that I am using only that method.

As to strychnin, some say strychnin must be given. Some say it must be given at the crisis, and others say it must be given from the inception of the disease. I do not believe the majority of cases will do as well under strychnin. I know they will not do as well under strychnin as under osteopathic treatment. I will not say they will not do as well as if under no treatment. It is possible that there would be an occasion for its use at the crisis, and I have seen such cases, and I have used it while studying medicine. I used it at the crisis, and I used it in cases where I am convinced that it helped them over the crisis, but I am also convinced now that by osteopathic treatment they would have done still better and the crisis would not have been so acute. In other words what strychnin does in favorable cases, osteopathic treatment does better in all cases.

In our post-operative cases study the charts and you will see that they do not have the acutely violent crisis that usually occurs under other treatment. They are under better control and if we can get them near the beginning, as we usually do, we can keep up the resistance so that where they would otherwise have a hard crisis they have an easy one. Instead of having a temperature of 105, pulse 165, respiration 70, or such a condition, they are more apt to run a temperature of 102, pulse 120, respiration 35 or 40 and they go through it without that suddenness and acuteness that is common under other methods of treatment.

In several instances, as an example of showing how this resistance is kept up, I had letters from boys in the camps. One letter told of a wide epidemic of severe tonsillitis. In one group of soldiers there were three osteopaths who treated all the men and this was

the only group that was not sent to quarantine. This group developed sore throat and was treated osteopathically and the sore throats checked so that quarantine was unnecessary.

Among the detailed reports in the A. M. A. Journal there will be nothing about this, nor about many other instances where osteopathic treatment, given by men forced to remain in the ranks, has done things that medicine cannot do. These examples are too frequent to be coincidents. If I had had three cases of post-operative pneumonia and they had all got well, it would not be surprising. If I had ten cases and they all got well, there are medical hospitals that have been this lucky. But there are no medical hospitals in the world that can report one hundred cases or two hundred cases or three hundred with developed pneumonia and all lived. The percentage of pneumonia cases that die now in medical hospitals, is much less than formerly. But the cause of this is not vaccine, antitoxin or drugs. It is due to the fact that pneumonia cases now, like typhoid, are given very little medicine and are turned over to general nursing treatment; that is, in the best medical hospitals.

The mortality is in inverse ratio to the drugs given. The advance medical teaching is against so much drugs in pneumonia, though of course the hick doctors use it because they are practicing medicine of the by-gone age, before Andrew Taylor Still forced on the world the idea partly started by homeopathy, that the less drugs the better. Homeopathy failed in not quite discarding drugs and in not having a substitute that reproved drugs.

As a matter of interest I wish to mention that while in medical college I had the advantage of being taught surgery by the greatest surgeon that ever lived, John B. Murphy. I only wish that circumstances could have permitted me to have shown him what osteopathy could do in post-operative conditions, because Murphy was a broad minded man and no man living ever thought less of orthodox medicine and old fashioned drug treatment than Murphy.

He and the Old Doctor would have been great friends had they ever met. Murphy, whom I considered a most wonderful surgeon, and whose skill I never hope to approach, stated to me many times while a student that he lost more cases from post-operative pneumonia than any other condition and that in upper abdominal conditions like gall bladder, stomach, and similar operations, post-operative pneumonia constituted the most of his mortality.

This great man was afraid of post-operative pneumonia, while I, a much less skilled surgeon, am no more afraid of post-operative pneumonia than I am of something occurring in a distant state because with osteopathic treatment, we have eliminated post-operative pneumonia as a fatal condition.

PART SECOND

INFECTIOUS DISEASES

Fever

=Fever= is due to various causes, so that a definite statement cannot always be given as to the cause of fever in every disease. Each fever case, like all other disorders, is a law unto itself; different causes are found in different cases. Moreover, often only theories, and not absolute facts, can be given.

Fever may be present when a local disease assumes a constitutional character or when the constitutional character is manifested from the beginning of the disease. Fever may be a systemic disorder or a symptom of disease, and is characterized by an increase of body temperature. Other symptoms are usually present, as an accelerated pulse, disturbances of distribution of the blood, increased catabolism, and disordered secretions.

=Etiology.=—In infectious diseases fever is due chiefly to the action of various toxic or harmful agents, produced by the disease, upon the fluids of the body and upon the nervous system. Disturbances of the thermogenic centers and nerves of the brain or cord by harmful agents, or by lesions of the anatomical structures affecting these nerves, are sources of fever. Also disturbances of the vasomotor centers (in the medulla and auxiliary centers along the cord) and nerves are causes of fever in many instances. A disturbed or lessened function of the nerves controlling sweating is an important factor. The multiplication of micro-organisms in the body, acting directly on the tissues or by producing toxic substances which affect the nervous system, is a fruitful source of fever. A few cases may be caused by direct affection of the nervous system, as is shown by appearance of fever in epileptic attacks, or by the passage of a catheter into the bladder. In a large number of all cases a demonstrable cause can be found upon careful examination, whether the fever be due to a necrosed mass of tissue, the introduction into the system of decomposed food,

infectious diseases, a lesion of some anatomical structure affecting a thermogenic, vasomotor or sweat center, a lesion to the innervation to the heart (vagi and cervical sympathetic) causing a rapid heart, or a lesion to the lymphatic system.

=Treatment.=—The treatment of fevers in a general way consists principally of thorough inhibition to the posterior spinal nerves of the upper cervical region in order that the center of the vasomotor system in the medulla may be affected, probably by the way of the superior cervical ganglion of the sympathetic. Thus the entire vascular system is equalized, for there is always a disturbance in the distribution of the blood in fever and if the center controlling the nerves that govern the lumen of the blood-vessels can be brought under control, there will result an equalization of the vascular system; if such occurs, health must ensue. Besides the vasomotor nerves to the blood-vessels being affected by this treatment, the nerves governing the lymphatics and the sweat glands will also be controlled. The sweat glands as a rule are rendered active by affecting directly the innervation of the glands, also the glands are controlled indirectly by the blood supply; this aids materially in lessening the temperature of the body. Treatment for a few minutes to the upper posterior cervical region would also affect the thermogenic centers and nerves of the brain reflexly in the same manner as the vasomotor and sweat centers and nerves are affected, thus tending to equalize the mechanism of the thermogenic system. Besides this action on the vasomotor, sweat, and the thermogenic nerves, there is produced an increased exhalation of moisture from the lungs, on account of an increase of vascular area in the lungs through vasomotor action. Also the large vascular area in the abdomen, under control of the splanchnic nerves, becomes constricted. Thus there is brought about a lessening temperature by evaporation, heat radiation, and perspiration; and an increased action of the general nervous system, a stronger cardiac force, an equalization of the vascular system, and a more perfect elimination of toxic properties by the skin, kidneys and lungs; consequently a reduction of the fever.

The foregoing treatment is successful to a limited extent, only in such cases where causative factors of the fever are involving the predominating centers controlling the heat production or dispersion and the vasomotor system directly; for if the lesion that is causing the disorder should be affecting an auxiliary center along the spinal cord instead of the predominating center, as is oftentimes the case, treatment of the predominating center would be useless as far as any permanent benefit is considered; although a temporary effect will be gained by lessening the fever at that point. Consequently, in many cases, the lesion lies within the jurisdiction of auxiliary centers which are situated at various points along the spinal cord. When such is the case, it will be of little benefit to give the cervical treatment. In such instances the lesion to the auxiliary center would have to be removed in order to cure. One cannot depend upon a set rule to reduce a fever; determine the cause, as in any other disease or symptom, and remove it.

In addition to the treatment to the cervical region and along the spinal column, as are indicated upon an examination, attention should be given to the heart's action. The equilibrium between the accelerator and inhibitory nerves (cervical sympathetic and vagi) should be maintained. The interchange of gases in the lungs should be rendered as nearly normal as possible; this is best accomplished by raising and spreading of the ribs from the second to the seventh dorsals, particularly in the region of the fifth and sixth. Also stimulation of the vagi will aid by increasing the motor power of the lungs. The kidneys and bowels should be kept active so as to favor a rapid elimination of various toxic properties; besides they have control over large vascular areas. Treatment over the ureters will prevent any clogging that might occur in them from a condensation of the urine. Attention, also, should be given the tissues at the fifth lumbar and over the iliac vessels to influence the circulation in the pelvis.

The =food= of the patient should be liquid—milk, soup, broths, etc., and almost any quantity of water allowed if called for, given little at a time and at frequent intervals. The room should be well lighted, ventilated, clean and kept at an even temperature.

=Two points= should always be remembered relative to fever:

First—That there are many causes of fever; and in order to reduce the fever the cause must be determined and removed, the same as in any disorder. A definite fever treatment cannot be given any more than a definite constipation treatment; the case must be seen in order to determine the cause.

Second—The reduction of fever is not necessary; the fever should be treated only as a symptom of disease when it exists as such. In fact, fever is beneficial, for it is one of nature's methods to relieve an over-burdened system from harmful agents, unless the temperature is excessive and continuous and is likely to cause more harm than the primary trouble.

Absolute =rest= in bed always is of decided benefit in lessening the temperature.

=Hydrotherapy= is of immense value in reducing a fever. It is an agent that has been greatly used, and if applied intelligently cannot but be of aid. There is much ignorance in regard to the principles and practice of hydrotherapy, not only among all classes of people, but among well informed practitioners in medicine. The most important function of the skin is as a heat regulator. Knowing this fact, the osteopath treats the vasomotor nerves that control the cutaneous circulation and the nerves that control the excretion of the skin; the nerve supply being from the cerebrospinal and sympathetic nerves. In many difficult and obstinate cases hydrotherapeutic measures should be used to aid the skin in regulating the temperature, as well as to enhance system functions for the same reason that osteopathic manipulations are given. Maintaining an equilibrium in heat production and heat dispersion is necessary in order that the standard of the body temperature may be kept; and the amount of the arterial blood circulating within a tissue determines its temperature.

The principal effect of water as a thermic agent when applied externally is due to the influence of the action of the water upon the cutaneous circulation. Lesser effects would be the mere extraction of heat from the body by evaporation and the equalization of temperatures of two bodies coming into contact. As the body is endowed with compensatory powers, this latter means would apply only to a limited extent. The temperature of the water used is important, as the colder the bath the less effective would its power be in reducing internal temperature. When a cold bath is used there is a driving of the blood away from the surface on account of the contraction of the peripheral vessels; consequently increasing the cutaneous circulation and cooling by radiation is prevented and less heat is lost. A collateral hyperemia occurs in the underlying parts which acts as a protection to the deeper tissues. The cold also inhibits the vasomotor nerves controlling the abdominal splanchnics, and thus a larger amount of blood passes to this immense vascular area. On the other hand, when a warmer bath is used the effect is opposite, and a lowering of the temperature is the result. The cutaneous vessels being dilated, the superficial blood is rapidly replaced by blood from the deeper vessels, thus allowing a cooling of the body to a large degree.

In the various fevers where hydrotherapeutic measures are employed, the object to be gained by such methods is not primarily an anti-thermic one but an anti-febrile reaction; consequently the use of cold water is employed. In mere heat reduction the warmer water would be more effective; but by the aid of the colder water the cause of the increased temperature, as in infectious fevers, is lessened; besides a refreshing and stimulating effect upon the entire system is gained. Thus the aim of the cold bath and friction, is not primarily to subdue the temperature by heat radiation or evaporation, but to correct disturbances governing the formation and the dissipation of heat caused by infectious fevers, and, moreover, to stimulate the nervous system, prevent heart failure, increase the eliminating power of the skin, kidneys and lungs, and to influence the corpuscular and chemical constituents of the blood to a more normal condition.

The full cold bath and friction (Brand Method) is commonly employed in infectious fevers. The half bath, wet pack, or sponging may be used. The modus operandi of each is given under the hydrotherapeutic treatment of typhoid fever.

Typhoid Fever

(ENTERIC FEVER)

In writing of these acute diseases which are self-limiting, it is understood that osteopathy aborts, overcomes symptoms and otherwise changes conditions frequently. When this occurs the case is not typical and it is a typical case which is here described.

=Definition.=—An acute, infectious disease caused by the bacillus typhosus. It is characterized anatomically by hyperplasia and definite lesions of Peyer’s patches and mesenteric glands, and enlargement of the spleen, and clinically by its slow onset, often diarrhea, abdominal tenderness, tympanites, fever, headache, and rose colored spots on the abdomen.

=Osteopathic Etiology and Pathology.=—Lesions to the lower dorsal and lumbar regions are always found, which impair the innervation and vascular supply of the intestines and cause defective nutrition. This is the most important predisposing cause, although general lowered vitality from overwork, improper food, unhygienic environment, and insanitary surroundings, are also of great importance. It is possible that one’s vitality may be so lowered that the bacillus of Eberth, if of sufficient numbers or virulency, will find a suitable medium wherein to multiply and grow, and thus the spinal lesions found in these cases are the result of reflex irritation. But the most probable underlying cause is the spinal lesion, and given two individuals with equal likelihood to infection, one with the spinal lesions and the other not, the former within all probability will be the more likely to suffer an attack. The severity and extent of the osteopathic lesion undoubtedly bears a direct ratio to the probability of attack from an infectious disease. Typhoid fever usually occurs between the ages of fifteen and thirty years. Some families are more susceptible than others. The autumn months, especially after a dry, hot summer, favor the disease. One may be reasonably certain that whenever there is a case of

typhoid the individual has not been careful as to diet, or drinking water, or some rule of health, and wherever there is an epidemic it can always be traced to insanitary surroundings, the water supply, contaminated garden truck or other food, sewage, etc.; although this does not preclude the probability that the osteopathic lesion or lowered vitality of Peyer's patches and mesenteric glands from other causes are important and many times primal etiological factors. The specific poison may be so virulent that practically no one escapes and again those of lowered vitality only will succumb to an attack.

The =exciting cause= is a special micro-organism, the bacillus of Eberth. The contagion may be carried through the air from one person to another, but this is rarely the case. Though the water is the most common mode of conveyance, the bacillus has been found during epidemics in both water and milk. The water may be contaminated by the intestinal discharges which have not been properly disinfected. Extreme cold does not destroy the typhoid germs. Milk may be infected from the milk-can being washed with the contaminated water or the unclean hands of the milker. In fresh milk the germs multiply rapidly. Salads, celery, ice and fruits may be contaminated. Oysters have become infected while being fattened or freshened. It is thought by some that the poison is not eliminated from the sick in a condition capable of transferring disease to a healthy person, but must undergo changes in the soil before it is able to cause the disease in another. Typhoid fever may be caused, however, by direct contact with the stools. Filth, sewers, or cesspools do not directly cause the disease, but they form a suitable medium for the preservation of the typhoid germs.

=Pathologically=, the characteristic lesions in typhoid fever consist of changes in the lymphoid elements of the bowels. These changes are most striking in the solitary glands and Peyer's patches. The alterations which occur may be divided into four well

BATHS AND BATHING.

CHAPTER I.

THE PHYSIOLOGICAL ACTION OF BATHS.

Since the influence of baths is exerted primarily upon the skin, and through the medium of the skin, upon the deeper-lying tissues and organs of the body, it is an absolute necessity for the reader at the outset to be made aware of the structure of the skin and its functions, as well as the relations which it bears to deeper-lying organs.

If the skin, say of the thumb, be looked at with a lens of moderate power, its surface is seen to be arranged in ridges and furrows, like a ploughed field; and at frequent intervals along the ridges are little depressions, which are known as the pores of the skin. These pores are the openings of the sweat ducts, and it is through these pores that the perspiration exudes. They are exceedingly numerous, and it has been calculated that there are as many as 2,800 to every square inch of surface, or about seven millions of them altogether. The ridges are seen to be divided into a series of minute hillocks, or _papillæ_, which are arranged in lines. These papillæ are the organs of touch, and are probably as numerous as the pores. They contain in their interior either loops of blood-vessels or nerve-endings.

These nerve-endings in the papillæ are of three kinds, which are readily distinguishable, and are known as tactile corpuscles, pacinian bodies, or end bulbs, according to the form which they take. Between the superficial and deep layers of the skin, the so-called cuticle and cutis, is a layer which partakes somewhat of the character of both. This is called the rete mucosum, and it is here that the pigment, found in the skin of the negro and in certain parts of the skin of white races also, is located.

Beneath the skin, in the subcutaneous tissue, are situated the sweat-glands, which are microscopical bundles of tubing, having one end running through the skin to terminate in the pores. These tubes are, or rather would be, if straightened out, about a quarter of an inch long; and it is estimated that the length of them in the entire body is about 28 miles! They pass through the upper layer of the skin or cuticle spirally, so that, although it is an easy matter for fluid to pass _out_, the passage in the opposite direction is by no means so easy. Each sweat-gland is plentifully supplied with blood-vessels, and is surrounded by a thin muscular coat, which is presumably able to exert, by its contraction, a certain amount of pressure, and so drive the secretions of the gland onward towards the pore, or external aperture.

The hair follicles, like the sweat-glands, are situated in the subcutaneous tissue. They are hollow receptacles, from the bottom of which the hairs grow. Alongside of each of these hair follicles is a pair of glands, called the sebaceous glands, which provide that small quantity of natural grease with which our hair is supplied. These glands resemble little bunches of grapes. The hair follicles are also furnished with a couple of small muscles, which, by their contraction, can cause a sensible erection of the hair. In certain parts of the skin there are glands which furnish a special odorous secretion. These are most plentiful in the arm-pits and between the toes. In the skin itself, and immediately beneath it, is a network of “lymphatic” vessels, whose function, it would seem, is mainly to drain the tissue of waste products. These vessels run towards the “lymphatic glands,” which, when enlarged, are often recognisable at the side of the neck, and which are very generally distributed throughout the body. In certain parts of the skin are special cells containing pigment.

Thus we see that the skin, which to the casual observer is an almost structureless membrane, is in reality a most complex and elaborate organ, richly supplied with blood-vessels, lymphatic vessels, and nerves, having its millions of papillæ and pores, and its miles of sweat-ducts. The hair follicles, with their sebaceous glands and muscles, are also to be reckoned by the million, and its odoriferous glands and special pigment-bearing cells probably by the thousand.

What are the various uses of this elaborate organ? In the first place, it serves as a protection to the softer parts beneath. Secondly, it serves to regulate the temperature of the body, by preventing, on the one hand, the too rapid radiation of the natural heat, and, on the other, by providing a very large surface for the evaporation of the constantly exuding perspiration, it prevents the overheating of the body. Thirdly, it is constantly removing from the body certain effete materials. These are the scales of the cuticle (which we remove whenever we wash and rub the surface), the perspiration, and the sebaceous, or greasy secretion. The amount of sweat varies immensely; it may be almost nil, or as much as a pint in an hour. The secretion of sweat is influenced by the temperature of the air, by exercise, by the drinking of fluids (especially warm fluids), and notably by the emotions. There can be no doubt that the secretion of a certain amount of sweat is necessary for perfect health; and it is the common experience of all that the checking of perspiration is very liable to be followed by dangerous internal congestion.

It has been demonstrated on some of the lower animals that, if the skin be shaved and varnished, death speedily ensues. This has been spoken of as a sort of cutaneous suffocation, death taking place owing to the charging of the blood with matter which should have been removed by the skin. It has been asserted, however, that death is due to cold in these cases; and it has certainly been demonstrated that animals so treated live much longer provided they be kept warm by a layer of cotton wool. Sometimes the skin is superficially destroyed by accidental burning or scalding, and it is well recognised that a burn or scald is dangerous to life in proportion to its superficial extent, rather than to its depth or severity.

The blood-vessels of the skin vary much in size under different circumstances, and the different degrees of pallor or redness of the skin are due to the condition of these superficial blood-vessels. The phenomenon of blushing is well known; and this should serve to remind us that the emotions can not only influence the amount of perspiration, but the size of the cutaneous blood-vessels. The intimate relations existing between the skin and the great nerve-centres should never be lost sight of.

The cutaneous blood-vessels enlarge in certain fevers, as scarlet-fever and measles; they can be made to enlarge also by the application of warmth, or irritants, such as mustard, or the stroke of a whip. Contraction of the blood-vessels is most marked in conditions of fear, or as the result of the prolonged application of cold.

Not only have the nerve-centres a great influence on the skin, but the skin is capable of exerting a great influence on the nerve-centres. This is not to be wondered at, when we bear in mind the myriads of nerve-bearing papillæ with which the skin is beset. When the soles of the feet are tickled, the legs are involuntarily moved; and when the arm-pits and sides of the chest are tickled, loud laughter is the result. These two phenomena are examples of what is known as _reflex action_, i.e., the tickling produces an effect upon the nerve-endings in the skin, and this effect travelling to the nerve-centres (the spinal cord or brain) is _reflected_ to the muscles, and produces movement of the leg or laughter. When the body is suddenly immersed in cold water, a not uncommon result is a shivering and a chattering of the teeth; and when cold water is sprinkled on the forehead or chest, deep inspiration and a catching of the breath is produced. These are examples of “reflex movements,” due to impressions made upon the nerves of the skin; and since many of the results of bathing are undoubtedly due to this kind of reflex action, it is very important to bear it constantly in mind. The connection between the nervous centres (the brain and spinal marrow) and the skin is shown also in the occurrence of what is known as goose skin, or _cutis anserina_, which is caused not only by the application of cold to the surface of the body, but even more readily by the mental states which make the “Hair of our flesh stand up.” The rationale of this phenomenon is the contraction and shortening of the little muscles which we have seen to be in intimate relationship with the hair follicles. There can be no doubt also that the pigment cells, which are scattered thinly throughout our skins, are subject to the control of the nervous centres, and it is well known that the tint of the complexion will sometimes vary with emotional states, as it certainly does with physical states. These considerations are sufficient to show that the skin plays a most important part in the animal economy, as a protective, a secreting, a vascular, and a nervous organ.

An all-important point to be determined with regard to the skin is its power of _absorption_--that is, its power, if any, of allowing substances to pass through it, and so reach the interior of the body. It is well ascertained that, if the surface of the skin be broken, absorption takes place with great rapidity, and that even when the skin is not broken, it is comparatively easy to get absorption of certain matters, such as mercurial ointment or extract of belladonna, provided they be applied with a certain amount of friction. We saw that the ducts of the sweat-glands perforated the skin spirally, and the friction has the effect of opening the mouths of these little ducts, so that the greasy or sticky preparation gets lodged within them and absorbed.

It has been proved with tolerable certainty that gases, such as carbonic acid and oxygen, are capable of penetrating and permeating the skin in small quantities, but it is extremely doubtful if water is ever absorbed through the skin. It has been attempted to settle the question by weighing the body before and after a prolonged immersion in the water, but such experiments are so beset

with fallacies that they are almost worthless. The fact that shipwrecked sailors are in the habit of successfully lessening their thirst by immersion of the body in water, or by wetting their clothes, is well known, but this effect may be due to the arrest of the cutaneous evaporation, or by an effect upon the nerves.

At all events it seems safest, in the present state of our knowledge, to assume that water is not absorbed through the skin; or if it be, that it is absorbed in such extremely small quantities that the effect of baths can in no sense be due to the absorption of the water in which the body is immersed. As to the absorption of the various salts contained in sea-water or mineral waters, there is no evidence whatever that these are ever absorbed even in the most minute quantities. If the salt dissolved in sea-water were absorbed through the skin, it is tolerably certain that sea-bathing, far from being the luxury which it is, would be regarded as a highly dangerous and most unpleasant practice.

Baths of all kinds serve, or may be made to serve, as vehicles for temperature, and by their aid we are enabled to surround the body with a temperature which is different to its own. Before we can fully understand the effect of hot and cold baths on the economy, it is necessary to enter into some discussion of the nature and source of the natural heat, of the body. The natural heat of the human body is between 98° and 99° of Fahrenheit's scale; and this temperature, roughly speaking, is uniformly maintained by the healthy body under all the varying circumstances to which it may be subjected. In the arctic regions, and in the tropics the temperature of the body rests at 98·6°; or, if variations occur, they are so slight in amount as to be hardly noticeable. In a cold atmosphere, therefore, the body has the power of maintaining its heat; and in a warm atmosphere it is equally able to maintain its coolness. This is a remarkable fact, and is due to the power possessed by the human body of adjusting the production and loss of heat. Heat is produced in the body by the combustion of food and tissues, exactly as heat is produced in a fireplace by the combustion of coal. The amount and rapidity of this combustion necessarily varies with the amount and nature of the food consumed and the activity of exercise and other vital processes. The most active tissue in the body is the blood; through its agency most of the combustion processes are carried on, and by its rapid circulation to all parts of the body the most distant points of the human frame are kept at the same temperature. The temperature of the blood is due to the amount of combustion taking place in the tissues, and the amount of combustion taking place in the tissues is due to the amount and energy of their blood supply, which last depends upon the force of the heart's action and the size of the blood-vessels which have the power of contracting and dilating, and which are subordinated to the regulating influence of the nerve-centres. If that part of the nerve-centres (the upper part of the spinal cord) which controls the size of the vessels be injured or destroyed, the combustion processes going on in the body seem to get beyond control and the temperature may be dangerously increased or decreased, the exact reason of one or the other phenomenon not being known. The limits of body temperature which are compatible with life are not very wide; for if the temperature rise to 109° or sink to 76° death will inevitably result, and a rise or fall of 7° from the natural temperature is decidedly dangerous. Seeing how narrow are the limits of temperature within which life is possible, we cannot but be amazed at the marvellous arrangements for maintaining the normal level of animal heat. The body is cooled by the evaporation going on from the lungs; by the more important evaporation going on from the skin (every one who has covered a portion of the skin with spirit and has encouraged its evaporation by blowing upon it knows practically the cooling effect of evaporation), and by the radiation of heat from the surface of the body, and the conduction of heat from the body by things in contact with it.

The _immediate_ effect of a cold bath is to chill the _surface_ of the body, the temperature of which, as tested by a thermometer, may fall several degrees. At the same time there is produced a pallor of the surface and goose-skin. While the surface is cooled, however, the blood itself undergoes an increase of temperature, due to an increase of the combustion processes going on in the body, of which we get additional evidence in the increase of the rate of the pulse and respiration, and an augmented discharge of carbonic acid from the lungs. There is a sudden sense of chilliness, and this impression, made upon the nerves of the skin, produces, by its action on the brain and spinal cord, some slight mental excitement and shivering of the limbs. After the bath has been continued some little time the temperature of the blood falls (sometimes as much as three or four degrees), the pulse and respiration get slow, the shivering gives place to lassitude, and the mental excitement to listlessness. On removal from the bath the phenomenon of "reaction" sets in. The vessels of the skin enlarge, the chilliness gives place to warmth, and the feeling of uneasiness is succeeded by a sense of comfort. This reaction follows most quickly when the bath is of short duration, and when its effects are suddenly induced. The shorter the bath the less is the ultimate depression of the temperature of the blood. The shorter the bath the greater is its power of _stimulating_ function; the longer it is continued the greater is the effect of _cooling_.

The effect of a _warm_ bath is to raise slightly the temperature of the surface and the temperature of the blood. The pulse and respiration are both quickened, and the escape of carbonic acid from the lungs is also increased. The blood-vessels of the skin get dilated, and the surface is reddened in proportion to the heat of the water. Warm baths of a moderate temperature can be borne for

a longer time than cold baths; but if the temperature be too high, and the bath too long-continued, faintness is liable to occur. On removal from the hot bath the skin is in a very delicate and susceptible state, and the vessels are liable to “re-act” in the direction of extreme contraction, in which case dangerous internal congestion may occur. If, however, the skin be protected, and the patient be placed in a warm room, or in bed, a violent perspiration will ensue. In the cold bath the muscles are liable to become stiff; but in the warm bath a stiff and fatigued muscle will resume its suppleness. After a hard day’s hunting a warm bath is a well-known and agreeable luxury.

The phenomenon which is popularly known as “reaction,” and which occurs after both hot and cold baths, is a most remarkable one, and seems to show that our bodies resent any interference with their function. Thus experiments have shown that if the temperature of a healthy man be raised or depressed by any artificial means, such as hot or cold baths, the subsequent reaction in the direction of the depression or exaltation of the temperature is such that the mean temperature of health is accurately maintained. A German observer, Jurgensen, found by a series of accurate observations on a patient who submitted to a series of baths of a temperature of 50° Fahr., each bath lasting twenty-five minutes, that notwithstanding the rapid abstraction of heat, which gave rise to shivering, lasting for several hours, the diminution of bodily temperature which occurred during the bath was followed, after an interval of four or five hours, by an elevation which precisely compensated it, so that the mean normal temperature was maintained in spite of the interference of the physiologist.

It will have been observed that the ultimate result of both hot and cold bathing, if conducted in moderation, is about the same, viz., an increased circulation of blood through the skin. In both cases also, the combustion going on within the body is increased, as evidenced by the escape of an increased quantity of carbonic acid from the lungs. In the case of the cold bath, this increased combustion is due to the stimulating effect of the cold water, while in the hot bath it is due to the artificial heat facilitating the natural combustion processes of the body. The effects of the hot and cold bath upon the combustion processes going on in the body may, not inaptly, be compared to the effect produced upon a furnace by the hot and cold blast, both of which encourage combustion and increase the heat given off by the furnace; but the hot blast so facilitates combustion that the same work is done by its aid, with an expenditure of 2-1/2 tons of coal, that is done by the cold blast with an expenditure of 8 tons of coal. If we want a fire to burn well, we have several courses open to us; the first is to poke it, which may be regarded as simple stimulation; the second is to supply it with a cold blast, in which case we supply large quantities of oxygen, but at the same time counteract the heating effect by the coldness of the blast. By employing a hot blast, the combustion is facilitated without any counteracting chilling. By each of these methods we hasten the ultimate extinguishing of the fire, unless fresh fuel be added. The employment of the hot blast entails the most economical use of the fuel.

It has been said, with regard to the use of baths, that _cold stimulates, but heat facilitates function_. “Between the two therapeutic opposites,” says Braun, “a similar relation exists, as between winter and summer life, and between sea and mountain air. The physician who has, to a certain extent, acquired an insight into the diseased side of mankind, divides the chronically sick into two groups, the one consisting of individuals whose organism has sufficient capital to afford the strong reaction required, the other consisting of persons needing nice management, and whose own power cannot be exposed to any great demand. For the one there is the system of exercise, cold treatment, cold baths, sea baths, and sea air; for the second, indulgence, warm treatment, warm climate, warm baths, mountain air.”

Seeing that both hot and cold baths increase the natural combustion of the body, it will be evident that persons undergoing a course of treatment by either method should be exceedingly careful that during the progress of their course of treatment the best fuel only is placed on the human furnace. They should eat the simplest and most nutritious food, and breathe nothing but the purest air.

CHAPTER II.

THE VARIETIES OF BATHS.

The _tepid_ bath has a temperature of from 85° to 92° Fahr., the _warm_ bath a temperature between 92° and 98° Fahr., and the _hot_ bath a temperature of from 98° to 112° Fahr.

The _cool_ bath has a temperature from 60° to 75° Fahr., and the _cold_ bath is of a temperature below 60° Fahr., downwards to the freezing point of water.

Hot or cold water may be used locally. We are familiar with the hip-bath and foot-bath, and occasionally we meet with baths of a special shape, made for the reception of the arms or hands, in cases where their local treatment has been deemed necessary.

Various plans have been devised for increasing the stimulating effect of water. One method of attaining this object is by keeping the water constantly in motion, as is done in the so-called _wave bath_, common in some parts of the Continent. Another way is by so increasing the size of the bath that the patient is able to move freely in it. In a big bath, not only is the good effect of exercise able to be added to that of bathing, but the concussion of the water on the surface of the body, and the constant change of the stratum of water in contact with the body vastly increases the power of the bath in influencing the temperature and stimulating the skin.

The best of all baths is the _swimming bath_, for in it the bather can indulge in a free exercise of his limbs, such as is hardly attainable under any other circumstances. Swimming is a very valuable exercise, because it employs the arms equally with the legs, and leads to a healthy development of the muscles of the chest. Nearly all good swimmers are big chested.

The _douche_ is a name given to a stream of water, either hot or cold, which is made to fall heavily or with force upon a part. It acts partly by the force of mechanical impact, and partly by its temperature. It is a very exhausting method of treatment, and must on no account be used too long. A column of water 12 feet high, allowed to fall upon the head, is so painful that Esquirol, who submitted to it, described it as resembling the continued breaking of a column of ice on the head, followed by a feeling of stupefaction, which lasted an hour afterwards. The douche was formerly much used in lunatic asylums, and was regarded as a specific against delusions, the unhappy creature possessed by delusive ideas being held beneath the douche until he recanted; and such was the agony thus caused, that the mere threat of the douche was often sufficient to control the wildest of maniacs. Those who have undergone the process of “shampooing the head,” as practised by the hair-dressers of our time, will remember the effect of a stream of cold water allowed to flow upon the head for too long a time.

The most powerfully stimulating action is obtained by the use of the _Scottish Douche_, which consists in the alternate use of streams of cold and hot water. By the hot stream the “reaction” after the cold stream is greatly encouraged. In most of the swimming baths to be found on the Continent, a pump is provided, in order that a patient may himself apply the douche to any joint requiring it, and at the same time encourage his reactive glow, by the exercise of pumping.

In most great bathing establishments two douches at least are provided, one called the _descending douche_, which may be applied to the head, shoulders, trunk, or limbs; and the other called the _ascending douche_, which is designed for throwing a stream of water into the bowel, a method of treatment which is advocated for conditions which it is unnecessary to discuss in this place.

Hot and cold affusion are merely mild forms of the douche.

The _shower bath_ differs from the douche only in the division of the stream of water by causing it to flow through a suitable colander. This method of treatment is severe and exhausting, and must be used with caution, especially with weakly people.

The _needle bath_ is merely a general shower bath. The bather stands within a coil of pipes which are finely perforated, and the water impinges in finely divided streams simultaneously upon every part of the body. It is a powerful general stimulant.

The _rain bath_ consists in the letting fall of large drops of water from a great height upon the part which it is wished to affect.

Packing with the wet sheet is a mode of applying water to the body which is the very reverse of some of the methods which we have been considering, since the stimulating action of the water is reduced to a minimum, and we get the refrigerating action only. It makes very little difference whether the sheet used be moistened with hot or cold water, since the temperature of the skin and the sheet very rapidly approximate in any case, and the more rapid evaporation of the hot water speedily induces a degree of cold quite equal to that of the cold sheet. The patient should be stripped naked and should lie upon a single blanket, the bed being protected by a mackintosh sheet placed between the blanket and the mattress. He is then enveloped in the wet sheet. If a maximum amount of refrigeration is desired he is left uncovered so that evaporation may be encouraged. If, on the other hand, we wish to encourage the action of the skin, several blankets are placed over the sheet.

Having discussed the various methods of using water as such for the purposes of bathing, we may next turn our attention to the _vapour bath_, which is a favourite method of making use of warmth and moisture. Here and there throughout the world there are to be found natural vapour baths; but, as generally employed, the vapour bath is a very simple contrivance indeed, merely consisting of an apparatus for conducting the steam of a kettle into a confined space in which the patient sits. The head of the

patient may be either placed in the bath or not, and the effects of the bath may be expected to differ according as the steam is inhaled into the lungs or not. The domestic vapour bath may consist of a flannel steam-proof cloak, which is worn by the patient, while beneath the chair on which he sits is placed a small portable kettle heated by spirits of wine for the formation of the steam. If the bather is unable to sit up, the steam may, with very great ease, be conducted beneath the blankets of a bed. The vapour bath can be borne much hotter than the water bath, the temperature varying between 120° Fahr. and 150° Fahr. The loading of the atmosphere with vapour, checks, or rather prevents, the natural evaporation of the perspiration, so that while the body is very strongly heated by the steam, the natural methods of cooling the body are arrested. From this it will be gathered that the power of the vapour bath to raise the body heat is very considerable, and indeed the temperature of the blood has been known to rise as much as 5° Fahr. during a bath. This power of raising the temperature of the body causes a very profuse perspiration, so that the vapour bath is recognised as one of the quickest and most effectual means of producing a copious action of the skin. The vapour bath can be locally applied in a very manageable way, and there is no difficulty in contriving an apparatus, by means of which the legs alone, or one arm, or one leg, may be subjected to the action of the vapour. If a quick reaction is desired a cold douche may be added to the steam, and the so-called _Russian vapour bath_ consists of a vapour bath of high temperature followed by a cold douche.

Air baths are baths from which we never escape except when we are taking a water bath, our bodies naturally being always surrounded by a layer of the atmosphere. _Cold-air baths_ are not much employed, although they have been recommended; and we have heard of persons who have sought to stimulate their skins and circulation by running naked in the open air. The _hot-air bath_ has always, at least since the days of ancient Rome, been a favourite luxury and means of treating disease; these baths, which are also called Russian or Turkish baths, consist really in a succession of processes, which, in the best establishments, are as follows: The bather is received at a barrier, where he is relieved of his boots and provided with check napkins in which to swathe himself while bathing. Passing the barrier he arrives at the tepidarium, a room of Eastern design, which attracts him by its coolness, quietness, and cleanliness. A marble basin, filled with water, into which a jet of water from a fountain falls with a soothing splash, occupies the centre, while all round are divans for reclining and conveniences for dressing and undressing. Through a Moorish arch at the end a glimpse is caught of the sudatorium, separated by a plate-glass partition from the tepidarium. Stripping himself naked and donning his checks, the bather passes into the sudatorium, an apartment with a domed roof, and having a marble floor and red-brick walls. The temperature of this room is about 120° or 150°, and here the bather sits, reading or otherwise amusing himself until perspiration is fully advanced. If perspiration is not free it may be encouraged by a draught of cool water, which will be tendered him by an attendant. If perspiration is slow in its advance, the heat of the room causes discomfort. Some burning of the skin, quickness of the heart’s action, and occasionally a throbbing tensive headache. A drink of water generally has the effect of causing the whole surface to bead with moisture, and then a sense of comfort succeeds to discomfort. Perspiration being fairly started it may be still further encouraged by removing into a still hotter apartment (of which there are three) varying in temperature from about 150° Fahr. to 210° Fahr. In these hot rooms (where it is necessary to wear thick list slippers to prevent the feet being scorched by the hot marble) the perspiration, in some persons, streams off the body, and when sufficient perspiratory action has been allowed, the bather returns to the body of the sudatorium, and, reclining on a marble slab, he is shampooed by an attendant. Next the whole surface is thoroughly washed with hot soap and water and the skin rubbed with a horse-hair glove; lastly, the process is finished by the application of cold water, which is done in one of two ways, either by the application of the cold douche, or by diving beneath the glass screen which separates the sudatorium from the tepidarium into the marble basin which fills the centre of the latter apartment. This done the bather is rubbed dry, and then indulges for half an hour in the _dolce far niente_, while he reclines on a divan, reads the paper, sips a cup of coffee and smokes a cigarette. As to the value of the Turkish bath we will speak hereafter, and we will content ourselves in this place by warning the bather not to “overdo” it. He should be guided by his sensations, and should not be tempted to go into this room or that room, or submit to this or that process merely because a friend does so with benefit, or without harm. He must remember that constitutions differ, and if the bath is followed by headache, or a feeling of faintness or lassitude or a want of appetite, he should take this as a warning that the treatment has been too heroic. The strongest Turkish bath is that in which the bather spends his time in the hottest room and finishes with the douche (a process which few can stand); the milder bath is that in which the highest temperature submitted to is about 140°, and the dive into the basin is taken in lieu of the douche. Those who take a Turkish bath for the first time should limit themselves to its milder form.

Mineral Baths are baths composed of water in which a considerable quantity of mineral matter has been dissolved, either by natural or artificial processes. It must be remembered that ordinary water is very far from pure, and that even rain-water, the purest of all natural waters, contains a considerable number of saline ingredients dissolved in it. Spring-water or river-water is very largely impregnated with matter which it has dissolved. The water of London contains from 18 to 20 grains of chalk in solution in each

gallon, besides other ingredients. The chief of all “mineral waters” is sea-water, and it is necessary that we should examine its composition somewhat closely. The specific gravity of sea-water is 1027, and the quantity of salt dissolved in it ranges from 3·5 to 4 per cent., being least in the Black Sea and the Baltic, and most in the Mediterranean. The following is the composition of the water of the English Channel:--

Water 963·8 Chloride of sodium (common salt) 28·0 Chloride of potassium 0·8 Chloride of magnesium 4·0 Sulphate of magnesia (Epsom salt) 2·0 Sulphate of lime 1·4 Bromide of magnesia } Carbonate of lime } Iodines } Traces. Ammonia } Oxide of iron } ------- 1,000·0 -------

Sea-bathing is a very popular form of the natural bath, and it is preferable to bathing in river-water or spring-water, because the sea is seldom so cold as are the latter. A sea-bath has also another great advantage over all other forms of bath, and that is that it is taken in the purest air possible; and in considering the effects of sea-bathing it is impossible to separate the effects of sea-air from that of the sea-water. The sea-bather is also constantly inhaling the spray of the sea-water, and thus obtains whatever benefit is to be got in this way. If he can swim he enjoys all the benefit of exercise. The motion of the water and the buffeting he gets from the waves act as a powerful excitant to the skin, and lastly, the salt in the water adds considerably to the stimulating action. Reaction more readily occurs after a sea-bath than after a river-bath, and thus the liability to “catch cold” is less, although the popular belief that it is impossible to take cold from a wetting with salt water is far from being true. Besides the water of the sea, there are many other _natural salt waters_ which have a great reputation both for bathing and drinking. These salt waters, which may be got of all strengths, from a strong natural brine to a water in which the salt is scarcely recognisable, all owe their stimulating power, as does sea-water, to the chloride of sodium (common salt) and other chlorides which they contain. Salt-water baths, or sool baths as they have been called, act as powerful stimulants to the skin, and have a very great reputation in Germany and other places, where the only seaboard is the ungenial northern coast.

There are many _natural mineral waters_ which contain ingredients other than common salt, and all of these are much used for bathing. We shall give some details of these when we come to speak of bathing resorts, and at present we shall content ourselves by giving merely a rough classification of them.

1. Many waters issue from the ground at a temperature sufficiently hot, or even too hot (e.g. the geysers in Iceland) for bathing. Some of these natural hot waters contain very small quantities indeed of mineral matters, and these are known as _indifferent thermal springs._

2. Mineral waters containing common salt have been already alluded to. They are known as _salt springs._

3. The so-called _alkaline springs_ contain as their chief ingredient carbonate of soda. These waters are more used for drinking than for bathing. The alkali which they contain helps undoubtedly to soften the skin of the bather, and acts probably also as a stimulant to the surface.

4. The waters containing bitter _purgative salts_, such as Epsom salt or Glauber’s salt, owe their reputation almost entirely to their power when taken internally. When used for bathing it is probable that these natural solutions of purgative salts are more stimulating to the skin than ordinary water.

5. The natural _chalybeate waters_, or waters containing iron, are but little used for bathing, and it is exceedingly unlikely that the iron contained in the water has any effect upon the bather.

Although we have classified the waters, and have used that classification which is generally adopted, it must be remembered that the ingredients of waters are always multiple, and we usually find that they contain alkaline salts, purging salts, iron salts, and brine salts mixed together, so that it is difficult sometimes to determine which is the predominating ingredient, and therefore to which class a mineral water properly belongs. All water contains gas of some kind dissolved in it, and it is well known that a glass of ordinary spring water may be seen to contain bubbles of gas which adhere to the sides of the glass, or come “winking at the brim.” The gases which waters principally contain are atmospheric air, nitrogen, carbonic acid, and sulphuretted hydrogen, and great stress has been laid upon the presence in bathing waters of the three last-named gases.

The action of bubbles of gas contained in water is, in part at least, easy to understand. These bubbles give great mobility to the water, and thus the particles of water in contact with the skin are incessantly changing. Gas is soon driven out of water by the application of heat, and it is only the cooler of the thermal springs which remain charged with any considerable quantity of gas after the natural pressure, to which they have been subjected in the earth, has been removed.

The bubbles of gas, contained in the various gaseous waters, resting upon the surface of the body, produce an agreeable sensation of mild stimulation not unlike that which we feel when the surface of the body is gently tickled. The gaseous baths belong necessarily to the category of cool baths, and it is important to remember that waters which have been boiled no longer retain any gas, which is all expelled during the process of ebullition. When a gaseous water issues from the earth at a temperature too low for bathing purposes, it is very important that the water should be heated only to the temperature required for bathing, which is generally between 60° Fahr. and 98° Fahr. This is effected usually by means of a coil of hot water or steam-pipes beneath the bottom of the bath, and, by turning a tap, the bath attendant can produce any temperature which may be desired in a very short time. Water which has been previously _boiled_ or _heated to a high temperature_, and has been allowed to cool to fit it for bathing purposes, contains very little or no gas, and cannot be regarded as constituting a gaseous bath. Intending bathers should inquire very carefully into the manner of heating baths at these establishments. If the natural gaseous water be collected in reservoirs, and be allowed to lie in these reservoirs for any length of time before being used for the baths, the greater part of the contained gas will escape, and there will be a great discrepancy between the actual condition of the water used and the published analysis of such water.

It is exceedingly unlikely that either carbonic acid or nitrogen contained in water is absorbed by the skin. The effect of these gaseous baths is due to their physical condition only (at least we have no satisfactory evidence to the contrary), and in no way to the absorption of the contained gases. Carbonic acid is only absorbed by the skin under the influence of great pressure, and when thus absorbed it produces a poisonous effect.

At some bathing establishments, so-called baths of pure carbonic acid are administered, the patient being made to sit in a reservoir of the pure gas, but, of course, with his head out. We have also seen arrangements for directing a jet of carbonic acid gas upon different regions of the body, but we should be sorry to hazard any opinion as to the _modus operandi_, or the results of such a practice.

In an ordinary water-bath, strongly impregnated with carbonic acid, there is occasionally some danger of too much gas escaping, and being consequently inhaled in undue quantities by the occupant of the bath.

Sulphur baths, or baths impregnated with sulphuretted hydrogen gas, and having the well-known and offensive odour of rotten eggs, have been used as remedies in disease from time immemorial. It must be remembered that the so-called “sulphur waters” are of a very complex nature, and contain many saline ingredients, in addition to the sulphides of lime or soda, to the decomposition of which the presence of the characteristic gas is due. Most of these waters have also a high temperature, so that they must be considered as hot salt waters, with the addition of sulphuretted hydrogen, and it becomes a difficult matter to determine to which of their ingredients any good effect which they may produce is due. It must be borne in mind, also, that the amount of sulphuretted hydrogen contained even in the strongest of these waters, notwithstanding that it is amply sufficient to offend the sense of smell, is in reality very small, and there is no evidence that this gas is ever absorbed through the skin from the bath. People who visit sulphur baths generally drink the water, and while bathing they certainly inhale an atmosphere more or less charged with sulphuretted hydrogen. The general opinion at present is, that the effect of sulphur waters, when used for baths, is the same as that of other hot and saline springs, and that the sulphuretted hydrogen in the water is inoperative. At some of the sulphur baths the attendants point to a peculiar eruption on the skin, called La Poussée, as evidence of the peculiar effect of sulphur, but this eruption does not differ from that which so often results after a prolonged use of baths of any kind.

There is no end to the varieties of baths which have been used at one time and another for the relief of sickness, and we shall content ourselves by a short allusion to some of the best known.

Mud baths, or moor baths, are much used in some parts of Germany. They consist of water mixed with moor earth, or the mud deposited by some of the mineral springs. The resulting compound is thick and stodgy, and, like loosely-made farinaceous puddings. They cool unequally, and retain their heat for very long periods in the middle. Chemically they are composed of the various matters, soluble and insoluble, animal, vegetable, and mineral, of which mud or moor earth is formed. Much of their virtue has been ascribed to _formic acid_, a volatile body formed by ants, having a very pungent odour and considerable stimulating power. These baths are generally supposed to exert a very powerful action upon the skin.

Pine baths are in great repute in regions where pine-trees are plentiful, as in the Black Forest, the Harz Mountains, and elsewhere. A decoction is made of the fragrant tops of the pine-trees, and this is added to the baths in varying quantities. It is also largely exported in a concentrated form from the regions in which it is made. The smell of the pine extract is most delicious, and the

resin which it contains has an undoubted stimulating action upon the skin.

Blood, milk and whey, as well as various broths and decoctions of meat, have been used in the belief that they imparted strength to the bather. It is indeed a practice in some northern countries, even in the present day, to envelop a weak or dying patient in the skin of a freshly killed animal, the invalid thereby being supposed to imbibe some of the vital power of the recently slaughtered beast.

On the banks of the Nile, _slime_ has been used as a bath, and in some places _sea-mud_ has been used for the same purpose. _Sand baths_, or arenation, belong to the remedies which are hallowed by antiquity. The patient is buried in the sand, and exposed to the full rays of the sun, and the combined effect of the heat and the surface irritation produces a copious perspiration. At some sea-bathing establishments _baths of sea-weed_ are given, under the name of ozone baths, from the belief, right or wrong, that sea-weed is impregnated with ozone. In some old works we find baths of _dung_ strongly recommended; and even at the present day it is the practice, among some of the half-civilised Eastern nations, to smear the body with dung for the cure of all varieties of ailments. Various refuse matters have been used as baths, among which we may mention the _husk of the grape_, in countries where the vine is largely cultivated, and the _refuse of the olive_ in oil-making countries.

Medicated baths may be artificially prepared, and many such are in common use in medicine. Among these we may mention--

1. The group of so-called _emollient_ baths, which have the following composition: To thirty gallons of water, there may be added from two to six pounds of _bran_; or a pound of _potato flour_; or a couple of pounds of _gelatine_; or a pound of _linseed meal_; or four pounds of _marsh mallow_, or other herbs.

2. _Alkaline baths_ are made by adding to thirty gallons of water, from four to six ounces of carbonate of soda or potash, and occasionally an equal quantity of borax.

3. _Acid baths_ contain an ounce or more of muriatic, nitric or nitro-muriatic acid, to each thirty gallons of water.

4. Iodine or Bromine may be added to baths.

The medicated vapour baths are of two kinds, _mercurial_ and _sulphur_, both being contrived by evaporating flour of sulphur or calomel in an iron pan. The sulphur bath thus administered emits the pungent and suffocating vapour of sulphurous acid, the effects of which must be exerted solely upon the body of the patient, since the inhalation of any quantity, if not fatal, would prove a very serious annoyance. We must not forget to mention the old domestic remedy of a bath of _mustard and water_, which is among the most powerful stimulants to the skin which we possess.

The _Galvanic Bath_ has been much talked about of late years, and it becomes necessary that we should discuss its merits. It consists merely of a bath of water, through which a galvanic current is passed. It can be easily administered in the following way:--Place an ordinary bath upon a sheet of mackintosh, which, being a non-conductor of electricity, has the effect of insulating the bath, as it is termed. Then fill the bath with warm water to a convenient height, and to the water add a handful of salt or a wine-glassful of vinegar in order to increase its conducting power. Next get a galvanic battery, one having 30 or 40 Leclanché Elements is sufficient, and place it on a chair or on the floor beside the bath. To each of the poles of this battery, positive and negative, affix a suitable length (3 or 4 yards) of insulated telegraph wire, having its extremities freed from the gutta-percha or other insulating material. Place a length of stout broom-handle across the bath, resting on its two edges, and round the middle of this twine the bright metal end of the wire in connection with the positive pole of the battery, covering it with a piece of flannel, or wrapping it round with a sponge. The bather then gets into the bath, and takes hold of the centre of the broom-handle, previously moistened, so that his hands are out of the bath. The end of the negative wire is then placed in the bath itself, and as this is done the bather will feel the shock of the electric current. The current in this case travels from the positive pole of the battery through the wire to the broom-handle, down the patient's arms, through his body to the water of the bath, and so to the negative pole. This form of bath is a very powerful stimulant to the skin, but beyond its action on the skin we know nothing. It is said that by its aid it is possible to extract metallic bodies, such as mercury or lead, which may be lurking in the body and causing harm. Of such a power there is no evidence whatever. We have heard it said that at some galvanic baths visitors have been shown discolorations on the side of the bath as evidence of deposits of mercury, &c., but this is merely a quackish imposition, and it is well that persons should be on their guard against it.

The _electro-magnetic_ bath is given in the same way as the galvanic bath, an electro-magnetic battery being substituted for the galvanic battery.

It will be well to close the chapter by offering a few hints to bathers, and by laying down a few rules for their guidance. Bathing, in all its forms, increases the internal work of the body; it increases the action of the heart, the rate of respiration, the rapidity of circulation, the rate of tissue change, and, in the case of hot baths, the rate of perspiration through the skin. This necessarily makes a call upon the vital forces, and causes a certain amount of exhaustion. From this it follows that baths are best not taken at a time when the body is much exhausted, and that exhausting exercise should not be indulged in after a bath until a considerable period of time has elapsed.

Again, since bathing invariably affects the distribution of the blood, causing, as the case may be, either a degree of bloodlessness in internal organs, or, if the bath be cold, an undue congestion of them, it is important not to overtax those organs during the period of bathing. It is, therefore, never advisable to bathe directly before or directly after a meal, since in both cases a want of digestion of the material in the stomach is likely to result.

Ancient writers are most explicit in their directions for bathers. Thus Hippocrates, the Father of Medicine, writing some four centuries before the Christian era, says: “The person who takes the bath should be orderly and reserved in his manner, should do nothing for himself, but others should pour the water upon him and rub him; and plenty of water, of various temperatures, should be in readiness for the _douche_, and the affusions quickly made; and sponges should be used instead of the strigil, and the body should be anointed when not quite dry.... And a man should not be washed immediately after he has taken a draught of Ptisan, or a drink; neither should he take Ptisan as a drink immediately after the bath.” These directions are for the use of invalids, such as are acutely ill, and the writer seems fully to recognise that bathing in itself is an exhausting process. This allusion to Ptisan is interesting, as showing how some of our commonest domestic remedies come to us from a remote antiquity. The Greek word πτισ■νη signifies peeled (or “pearl”) barley, and the drink made from it, the barley-water of to-day.

As we have before mentioned incidentally, the proper ventilation of the bathroom is a matter of prime importance; for since the respiration is quickened by the act of bathing, it is evident that a foul atmosphere in the bathroom is very liable to produce an ill-effect upon the bather. Many of the swimming baths in London are very defective in this respect, and we have been forcibly struck, in more than one of them, by the ammoniacal odour proceeding from those sanitary offices which are a necessary adjunct to every bathing establishment. It is a very common custom in private houses to place the bath and the water-closet in the same apartment. That this is an undesirable arrangement is evident, for the water-closet is, of all places in a house, that in which a foul atmosphere is most likely to be encountered. Although a bathroom should be well ventilated, it should certainly not be draughty, for currents of cold air blowing upon the moist skin of the bather are likely to give “cold,” and produce internal congestions of various kinds. In summer there is no difficulty in providing a sufficiency of fresh air, but in winter it is not so easy. The best way, perhaps, to provide for a constant renewal of air is to admit air by means of vertical tubes, and to have in the room an open fireplace, in which a brisk fire should be burning while the bath is being administered.

In order to ensure a proper reaction after a cold bath, and to prevent chill after a hot one, it is customary to provide the bather with a supply of hot linen. This is a great comfort and a luxury, and may even be looked upon as an absolute necessity for delicate persons. It is a very general custom on the Continent for the bather, after removing the greater part of the moisture from his body, to don a hot calico Peignoir, or bathing-gown, which protects from chill, and at the same time allows of the limbs being rubbed with towels. It is not necessary to say much about towels. They are to be got of all qualities, from those as soft as a cambric handkerchief to those which, in roughness, approach the qualities of a curricomb. The bather may please himself in this matter, and will choose a soft absorbent towel to remove the moisture, and a hard one to rub the surface and produce the necessary reaction. Horsehair gloves and various rubbers made of indiarubber, &c., are in use, and require only to be mentioned.

Friction and shampooing are valuable accessories to bathing, and serve, as it were, to take the place of exercise in those diseases in which the patient is unable to exercise his body thoroughly for himself. Friction is applied to the skin merely to rub off the surface layers of epithelium, to encourage the dilatation of the superficial vessels, and the transudation of the sweat. Shampooing is a deeper and more forcible kind of friction, in which the rubber kneads the muscles and allows his fingers to press steadily upon and between them. This acts as a stimulant to the muscles themselves, much in the same way, but in a far milder degree, as an electric battery acts upon them. It must be borne in mind, however, that friction and shampooing are both exhausting, and must not be used to excess. While a patient is being shampooed, he involuntarily resists the pressure of the shampooer, and we have seen a patient reduced to a state of considerable exhaustion, after having been for twenty minutes in the hands of a professional rubber.

It is not necessary to make any remarks on the subject of soaps. Their name is Legion, and the bather, guided by the light of common sense, may make his choice. The ancients were accustomed to anoint their bodies with a variety of smegmata, unguents

and oils, both during and after bathing.

As to the temperature of the bath and its duration, although these are both very important questions, it is impossible to lay down any exact rules, for they must be settled according to the condition of the bather. A physician, in ordering a course of baths for an invalid, should state, in writing (in the form of a prescription) the frequency, variety, temperature, and duration, as well as the time of day at which they are to be taken.

After a hot bath it is sometimes necessary to arrange that a weakly patient shall go to bed for a couple of hours or more. To slake the thirst, both during and after a bath, there is nothing better than pure water.

CHAPTER III.

BATHING LOCALITIES.

In considering the various bathing localities it is only natural that we should begin with London. We have no intention of speaking in detail of the various baths with which private enterprise has provided the inhabitants of London, for such a course would be quite foreign to the intentions of this little work, which is intended merely to furnish the reader with a few general principles which shall be of use to him in selecting a bath. There is no kind of bath which cannot be got in London, and between a dip in the Serpentine and the elaborate process of the Turkish bath the bather has a wide choice. In proportion to its size and the number of its inhabitants, however, the bathing accommodation is very bad. The Thames is still a foul stream, and few care to plunge into the sewage which flows down from Richmond and surges back again from Barking. It is true that we have one large swimming bath floating close to Hungerford Bridge, the water of which is filtered in an ingenious way; but it may safely be said that, were the water of the river cleaner, we should have fifty such baths instead of one. We have often thought that a bathing establishment on a really grand scale would be a success in London, and we hope some day to see baths in our great metropolis, which should remind one of the palatial establishment of Caracalla. A combination of a swimming bath, private baths, Turkish baths, &c., with a first-rate gymnasium, reading-room, lecture hall, and refreshment room, would surely meet with sufficient patronage to pay, and we even believe that the introduction of sea-water for such a purpose (an undertaking which has been started more than once) would be sufficiently appreciated to ensure a dividend to the promoters.

England is naturally very well supplied with sea-bathing resorts, and it is possible to get a sea-bath in our island combined with any variety of climate, from the cold and bracing to the mild and relaxing. Sea-air, the great value of which is well understood as a curative agent, has certain peculiarities. It is necessarily the purest air that can be got, and when the breeze is off the sea the air comes to the shore practically uncontaminated and free from the exhalations of animals or furnaces. It is said to be very rich in ozone, and it certainly contains fine saline particles supplied to it by the sea-spray, and possibly small quantities of iodine, which give to the sea-breeze that peculiar odour which it undoubtedly possesses. Sea-air is dense, and the barometer stands at its maximum at the sea-level. Sea-air is warmer than the air of inland places, and it is more equable in its temperature owing to the comparatively slight changes in temperature which the sea itself undergoes. The effect of sea-air is very stimulating, and sojourners by the sea have their appetites increased and their vital functions quickened. While speaking of sea-air we must remind the reader that the air of the seaside places is often far from good, owing to the defective sanitary arrangements. There are not a few towns on our coasts, the sewers of which are taken out on to the beach where visitors most do congregate, and the smell of sewage at low tide is often far from pleasant. In selecting a sea-bathing place it is of importance to attend, not only to the aspect and general situation of the town, but to inform oneself whether or not it be thoroughly drained, the sewers being carried either inland to a proper sewage farm or far out to sea well beyond low-water mark; whether the water supply for drinking purposes be good and abundant, and whether the general cleanliness of the town is properly attended to. Climate is a very local phenomenon, and it is of as much importance to see that the bedroom and sitting-room which an invalid has to occupy are well ventilated and have a good aspect, as to attend to the latitude and general aspect of the locality chosen. It is of little use to send a patient to the sea if he has to spend the greater part of his time in small rooms made unbearable by gaslights or the defective drainage of the house; and an invalid with delicate lungs will derive but little benefit from a sojourn in the south if his windows face the north and he is afraid to open them.

As to the time of year at which sea-baths should be taken, that of course depends upon the locality visited. On the east coast, in situations which are exposed to winds from the north and east, bathing is only advisable during the three summer months of June, July, and August. On the west coast it is possible to begin a little earlier, and continue a little later; and in some situations in the south, the season may be said to extend from the middle of April to November. In these latter places, the temperature at

midsummer is often unpleasantly high, and the bathing season falls into abeyance for a time. There are many considerations which influence people in their choice of a bathing station, such as the size of a town, or whether it be gay or quiet; its distance from London, its accessibility, the accommodation, the expense, &c. A more important point, perhaps, is the nature of the bottom, whether it be sandy or shingly. The great popularity of the bathing resorts on the north coast of France and the Belgian coast is due to the great expanse of fine sand of which the bottom is composed.

In selecting a bathing place it is advisable, if reliable information is not forthcoming from those who know it well, to look at the Ordnance map of the town and district, and learn from an inspection of it, not only the direction in which the locality looks sea-ward, but the nature of the immediate surroundings of it; the position and height of cliffs and hills, and the amount of protection against cold or heat. The nature of the soil should also be ascertained, and the prevailing character of the vegetation, and, if possible, the amount of rainfall and the mean temperature of summer and winter.

Many watering places possess, in a very restricted area, many climates. Let us look at such a watering place as Bournemouth, and we shall be able to explain what we mean. Bournemouth is a town of some six or seven thousand inhabitants, built on a sandy soil, surrounded by pine woods. It faces the south; the average rainfall is 30 inches per annum; the temperature is equable, and frosts are comparatively rare, the mean night temperature in the month of January being 35·6. The town is built upon two bold cliffs, with a dip between them, and the surface of the soil being very uneven, it is thus possible to get almost any climate. In the dip between the cliffs are situations exposed only to the south, and protected from all cold winds; and others facing only to the north. On the east cliff one may live in a pine-wood, with the advantages of moderate elevation, a southern aspect, and the protection of trees which have the double advantage of being evergreen, and possessing a foliage which does not rot and decompose in autumn. On the west cliff, again, one may live in a house exposed to every wind that blows, in a climate which may very justly be spoken of as bracing.

It seems unnecessary to catalogue the various sea-bathing resorts in Great Britain. They are numberless, and intending visitors are influenced mainly by questions of accessibility and accommodation. Those on the east coast are mostly bracing, those on the west are more relaxing, while those on the southern coast are mostly warm and available during the winter months. We must refer our readers to the various guide-books and gazetteers for detailed information.

We have next to consider the various mineral baths scattered about Europe, and it must be admitted that the arrangements for bathing at the various sources of mineral waters are much better carried out on the Continent than in this country. In any course of treatment bathing is generally only one element of the regimen to which an invalid is directed to submit. Diet, climate, rest, and exercise, and the internal administration of medicine or of mineral water, often are called into requisition to perform their share in the cure; and while a patient is bathing, and by bathing is stimulating or facilitating his animal functions, it is of the greatest importance that he should live the healthiest life imaginable. At most of the German baths a somewhat strict surveillance of the bathers is maintained, and at those which have the greatest reputation, it is almost impossible to get, in the shape of food, anything of which the local physicians would disapprove. It is too often the habit of the Englishman to go to a bath without taking any advice as to his general mode of life while bathing, or even whether he may expect benefit or harm from the treatment he is prescribing for himself. The foreigner, on the other hand, submits in all things to authority, and while “undergoing a cure” he is content to have his time of rising and going to bed, his meals, his exercise, his baths, and other treatment, all accurately regulated for him. It is on this account, no doubt, that the German and French baths have so great a reputation, for while visiting them the guests live by rule just as athletes do in this country when they wish to bring themselves to the highest pitch of health attainable in view of some muscular contest. When the Englishman is told to visit this or that continental spring, he may well ask, as did the captain of the host, “Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel? May I not wash in them, and be clean?” He must remember, however, that, as in Naaman’s case, obedience to the directions of the prophet resulted in a cure, so he must seek out a spring where he will find a prophet; to whose dictation he must be willing for a time in all things to submit.

When people visit a mineral spring they generally do so with the double object of drinking the water and of bathing in it; with the drinking of mineral water we have, in this volume, nothing to do, but merely with bathing, and the reader will have gathered from the previous chapters, that, when bathing only is concerned, the exact composition of the water is not a matter of very great importance; since all baths act in the same way, by stimulating the skin, and the water of the bath is probably _never absorbed_. It is important to insist upon this point, because we find in several bath-puffs the assertion that their effect is due to the absorption through the skin of the material dissolved in the water of the bath. Such an assertion is contrary to the teaching of our leading physiologists. At all sea-bathing places the climate is, in one respect, the amount of barometric pressure, similar. The advantage of mineral baths over sea-baths very greatly lies in the fact that we are not only able to choose our water but also to choose our

climate, and to have either a mountain climate with low barometric pressure, or a sea-level climate with a high barometric pressure, or a climate where the barometric pressure is intermediate between these two extremes.

We must, in order to bring the effects of mountain climates vividly before the mind of the reader, refer again to the comparison which we have made elsewhere between the burning of fuel in a furnace, and the combustion which is constantly going on in our bodies. Experiments made by Professors Tyndall and Frankland on the combustion of candles at different altitudes, seem to give the clue to the explanation of the effects of mountain air upon our bodies. These gentlemen burnt candles of equal weight, and under similar conditions at Chamouni, and also on the top of Mont Blanc, which is 12,000 feet higher. They found that the amount of candle consumed in equal periods of time was the same in both situations, but that on the top of the mountain the candle gave out considerably _less light_ than it did in the valley. The diminution of the light was attributed with justice to the _completeness_ of the combustion, for the light emitted by a flame is mainly due to the unconsumed particles of carbon in a state of incandescence. Mountain air, being much more rarified than the air of low-lying valleys, contains much less oxygen in proportion to volume, but its lesser density seems to enable the oxygen to assume, as it were, a greater activity.

It has also been found that bodies lose heat less rapidly in rarified atmospheres, so that presumably there is less need for heat-production on the mountain than on the plain; so that in mountain climates the body is saved a certain proportion of the combustion necessary for the generation of heat.

Mountain air is pure, and removed from miasmata and exhalations, whether from marshes or (being usually sparsely inhabited) men. It is usually still and seldom foggy. The variations of temperature are very great and very rapid, the visitor having often to undergo, within a few hours, a tropical and an arctic climate. These rapid variations serve probably to stimulate vital processes, and there can be little doubt that they are important factors in the general effect produced by mountain climates.

The following notes made during a sojourn at Davos in Switzerland may serve to bring some of the above facts in a more concrete form before the reader. “The height above sea-level is between 5000 and 6000 feet, and the barometer stands at about an average of 620 millimètres, instead of 760, which is its average height at the sea-level, so that the weight of the atmosphere is only 620/760, or rather more than three-fourths of what to most of us is its normal weight. The result of this is that under the influence of the sun’s rays evaporation is marvellously rapid. The dew is gone in an instant, and the vapours of the early morning seem to vanish at the first touch of the solar heat. Thus it follows that although the rainfall is considerable, the dryness of the air is, during the main part of the day, nearly absolute. The range of temperature is apt to be very great, and the thermometer, even in the height of summer, is frequently below freezing point in the early morning and in the shade, while in the sunshine, towards midday, the heat is simply scorching. For the most part, however, the temperature is very pleasant in summer; and even invalids, if properly provided with wraps, may spend almost all the hours of daylight out of doors. The obvious results on a healthy person of living in such a climate are (1) a slight increase in the rate of pulse and respiration; (2) a craving for and an ease in performing muscular exercise; and (3) a marked increase of the appetite, with a general feeling of exhilaration. The air acts, in fact, as a powerful stimulant. Ladies, and those who are not able to take much exercise, often have a difficulty in sleeping, but this is never of long continuance. Owing, it is said, to the diminished atmospheric pressure, the cutaneous blood-vessels dilate, and the complexion becomes (with the help of the sun) exceedingly ruddy, a fact which is particularly noticeable in the inhabitants, whose red cheeks strike a stranger with astonishment.”

There are of course many things to be considered in making selection of a bath besides the height above sea-level. Attention must be paid to the local configuration of the district, and the sanitary condition of the town or village in which the healing spring is situated. It is manifestly unadvisable for an invalid who has been sent to the Alps for the benefit of a mountain climate to settle down in some narrow gorge, exposed perhaps, only to one wind, into which the sun only peeps at midday, where the climate knows no medium between the two extremes of heat and cold, where the river perhaps has been converted into an open sewer by the inhabitants, and where the population is a mixture of the Goitrous and the Cretinous. Such localities are to be found, and it may well happen that the invalid may go to the bath to be cured of his gout, and return with typhoid or ague. Some few years back the writer was travelling in the Vosges mountains, and stopped a night at a well-known watering-place, taking up his abode in the Bad-haus. The situation of the town was extremely picturesque; the valley in which it lay was verdant, the hills were well clothed with foliage, and the mineral springs of the district were such as might well be recommended to many patients. The inhabitants, however, had seen fit to turn the lovely stream which meandered through the valley into a sewer. Into it abominations of every kind were thrown, and its pebbly bottom had become obscured by broken crockery, old tin pots, old boots and shoes, and other refuse. The swine were driven into it every morning as if on purpose to defile it, and what should have been one of the chief attractions of the district had become a pestilential nuisance, exhaling filthy odours, and fit only to be bridged over and hidden absolutely from the light. It is

not sufficient in making choice of a bathing place to consider only those dry facts which are capable of being stated in figures, but the intending bather should seek reliable information as to the sanitary condition of the town, as well as of the hotel or lodging-house which he proposes to inhabit. This information is only to be got from disinterested patients who have made a sojourn in the locality. Guide books are seldom to be trusted, and special treatises on the virtues of this or that bath are to be regarded as the works of a fervid imagination in the absence of confirmatory evidence. The most potent cause in establishing the popularity of this or that bathing place has been the heat of the water, and there is perhaps no hot spring in Europe which was not used for bathing by the Romans, or which has not been used from times of remote antiquity by the inhabitants of the district. It is so convenient and so cheap to have hot water ready to hand without the necessity of huge furnaces, enormous chimneys, expensive boilers, and endless pipes, that it is not surprising that such a valuable natural gift should be appreciated.

The best known hot bath in this country is the one at _Bath_, in Somersetshire, the water of which proved so attractive to the Romans that they founded the city of _Aquæ Solis_ here, in the 1st century of the Christian era. It is needless for us to dwell upon the popularity of Bath. There are four hot springs here which vary in temperature between 120° Fahr. and 104° Fahr. The supply of water is ample and abundant, and the accommodation for guests such as can hardly be surpassed. The corporation of the city have lately erected a magnificent suite of baths, and if they will but turn their attention to the condition of the river Avon, and rigidly enforce the provisions of the Pollution of Rivers Act, Bath may again become as popular as it was in the days of Beau Nash. The elevation of Bath above the sea-level is only about 100 feet. The constituents of the Bath water are chiefly sulphate of lime with a little carbonate of iron, together with some free carbonic acid and nitrogen. It has been called an earthy water, but perhaps it is better to regard it as a simple hot water, the chief virtue of which is its warmth.

Buxton, in Derbyshire, is situated nearly 1000 feet above the sea-level in an open hollow surrounded by hills. There is good reason to believe that the water of Buxton was known to the Romans. The temperature of the Buxton water is 82° Fahr. The amount of saline ingredients is but small. The water is, however, impregnated with a large quantity both of carbonic acid and nitrogen gas. The town is amply provided with accommodation both for bathing and lodging.

At _Clifton_, near Bristol, there are springs having a temperature of 74° Fahr., and at _Mallow_, in Ireland, is a spring having a temperature of about 70° Fahr., and containing, like the water of Buxton, a large quantity of free nitrogen gas. A great deal has been written about the virtues of free nitrogen in water, but without, as it seems to us, sufficient evidence.

There are many hot springs in Europe which are very largely frequented by invalids. We can, however, do little more than tabulate the chief, indifferent, and earthy thermal springs, giving the chief facts concerning each.

At _Leuk_, in Switzerland, situated at the foot of the Gemmi Pass, we find a water possessing a natural temperature of 102° Fahr. to 120° Fahr., situated 4600 feet above the sea-level. The water is indifferent, and it is the custom here for bathers to remain many hours consecutively in the water. Ladies and gentlemen bathe in the same bath, and it is no uncommon thing for the bathers to be seen taking their luncheon or playing dominoes upon floating tables.

At _Pfaffers_ and _Ragatz_, near the town of Coire, in Switzerland, are found indifferent springs, situated between 1500 and 2000 feet above the sea-level, and having a temperature of 100° Fahr.

Gastein is a much frequented and very fashionable bath in the Austrian Salzkammergut, some twelve or thirteen hours' drive from Salzburg. The height above sea-level is 3300 feet, and the temperature of the water varies from 96° Fahr. to 114° Fahr.

Bormio, at the foot of the Stelvio Pass, on the southern slope of the Alps, has an altitude of over 4000 feet, and water of a temperature of 104° Fahr.

Wildbad, in the Black Forest, has been for many years a favourite bath with the English. The elevation is 1300 feet, and the temperature of the water a little over 100° Fahr.

Wiesbaden, the capital of Nassau, possesses both hot and cold springs. The former have a temperature of 160° Fahr., and contain a fair amount of chlorides. The town is beautifully situated among the Taunus Hills, and has an elevation of 300 feet above the sea-level.

Teplitz, in Bohemia, is a fashionable bathing resort. The town is well ordered, and healthfully situated, being 600 feet above the sea-level, and supplied with natural thermal springs, having a temperature ranging from 78° Fahr. to 120° Fahr.

Schlangenbad, among the Taunus Hills, is a quiet bathing-place, with a natural tepid water having a temperature ranging between 80° and 90° Fahr. The Schlangenbad water only contains 2-1/2 grains of solids to the pint, so that it may safely be regarded as an “indifferent” spring. Sir Francis Head, the author of the ‘Bubbles from the Brunnens of Nassau,’ visited Schlangenbad in 1836, and we feel constrained to make the following extract from his work, as typically illustrating the kind of belief which gathers round a natural spring:--

“In the history of the little Duchy of Nassau, the discovery of this spring forms a story full of innocence and simplicity. Once upon a time there was a heifer, with which everything in nature seemed to disagree. The more she ate the thinner she grew; the more her mother licked her hide, the rougher and the more staring was her coat. Not a fly in the forest would bite her; never was she seen to chew the cud, but, hidebound and melancholy, her hips seemed actually to be protruding from her skin. What was the matter with her no one knew; what could cure her no one could divine. In short, deserted by her master and her species, she was, as the faculty would term it, ‘given over.’ In a few weeks, however, she suddenly reappeared among the herd, with ribs covered with flesh, eyes like a deer, and skin sleek as a mole’s; breath sweetly smelling of milk, saliva hanging in ringlets from her jaw! Every day seemed to re-establish her health, and the phenomenon was so striking that the herdsman, feeling induced to watch her, discovered that regularly every evening she wormed her way in secret into the forest, until she reached an unknown spring of water, from which, having refreshed herself, she quietly returned to the valley. This trifling circumstance, scarcely known, was almost forgotten by the peasant, when a young Nassau lady began to show exactly the same incomprehensible symptoms as the heifer. Mother, sisters, friends, father, all tried to cure her, but in vain, and the physician had actually

‘Taken his leave with sighs and sorrow, Despairing of his fee to-morrow,’

when the herdsman, happening to hear of her case, prevailed upon her at last to try the heifer’s secret remedy. She did so, and in a very short time, to the utter astonishment of her friends, she became one of the stoutest and roundest young women in the duchy.” Sir Francis Head goes on to describe how he was conducted along subterranean passages to the source of the baths, and was astonished to find serpents swimming in the water, and still more astonished to hear his cicerone declare, “_C’est ce qui donne la qualité à ces eaux!_” Schlangen, or serpents, are very common in this part of the duchy of Nassau, and hence the name Schlangenbad.

Baden-Baden is at once one of the most frequented and most picturesque baths in Europe. The temperature of the water varies from 115° Fahr. to 144° Fahr, and the elevation above the sea-level is 616 feet. The waters contain only 22 grains of solid ingredients to the pint, the chief of which is common salt (16-1/2 grains).

The celebrated hot purgative water of _Carlsbad_, although formerly used for bathing, is now chiefly employed for drinking.

Bathing is carried on to a very large extent at _Vichy_ (in the Department of Allier, in France), although these waters are chiefly used as internal remedies.

Plombières, among the Vosges Mountains, has an elevation of 1310 feet. The water contains only 2 grains of solid ingredients to the pint, but the temperature is high, varying from 80° Fahr. to 160° Fahr.

Some of the hot springs at _Ems_, such as the Fürstenbrunnen, with a temperature of 95° Fahr., and the Neuequelle, with a temperature of 117° Fahr., are used for bathing.

At _Aix-les-Bains_, in Savoy, 768 feet above the sea-level, will be found two hot springs, varying in temperature from 106° Fahr. to 116° Fahr. These waters contain less than 4 grains of solid ingredients to the pint, but one of them, containing an appreciable amount of sulphuretted hydrogen, is known as the sulphur spring. Aix was known to the Romans, and in the modern town will be found every bathing appliance which art can contrive.

At _Mont Doré_ and at _Bourboule_, in the department of Puy de Dôme, in France, at an elevation of 3400 feet above the sea, are thermal springs having a temperature of 104° Fahr. to 114° Fahr.

Having enumerated the chief warm baths in Europe, we will proceed to catalogue some of the best known of the salt baths.

Droitwich, in Worcestershire, is perhaps the only place in England where concentrated salt baths can be obtained. The brine of Droitwich is said to contain as much as 2760 grains to the pint. The town is uninteresting.

At _Ischl_, in the Salzkammergut, is a concentrated brine containing 1900 grains to the pint. It is 2000 feet above the sea-level, and the country is charmingly picturesque.

Kreuznach, not far from Bingen on the Rhine, has a strong salt spring, and is much resorted to by scrofulous patients. The mother-lye of Kreuznach is said to contain 2400 grains to the pint. These strong brines are only used after proper dilution.

The water of _Soden_, in the Taunus hills, contains 160 grains to the pint; and at _Homburg_ are found several springs which have about 90 grains to the pint.

Kissingen is a fashionable watering place in the north of Bavaria, with an elevation of about 800 feet above the sea-level. Here will be found all the accessories of bath life. The water contains about 60 grains of solid ingredients to the pint.

The _Wood Hall Spa_, near Lincoln, is a salt spring containing as much as 160 grains to the pint.

Rehme, in Westphalia, is situated on the Cologne and Minden railway. The water has nearly 250 grains of salt to the pint, and is very highly charged with carbonic acid. The natural temperature of the water is 92° Fahr. There is every facility at Rehme for administering baths of all kinds and of all degrees of concentration.

Nauheim is not far from Homburg, among the Taunus hills, and possesses a water very similar to that of Rehme, having from 170 to 291 grains to the pint, being highly charged with carbonic acid, and having a temperature of from 80° Fahr. to 94° Fahr. The elevation of Nauheim above the sea-level is 450 feet. The salt baths of Rehme and Nauheim enjoy a very wide reputation.

Although sulphur waters are not so much used for bathing as formerly was the case, this little book would not be complete without some notice of the chief sulphur springs.

Harrogate, in Yorkshire, has been well known for more than three centuries, and although the sulphuretted hydrogen, by its predominant smell, gives the chief character to the Harrogate springs, they have an equal claim to be called saline or chalybeate, for they are strongly impregnated with salt and with iron, so that the taste has been compared to a mixture of rotten eggs and the scourings of a gun. The old sulphur spring contains 137 grains of solid contents to the pint, and is strongly impregnated with carbonic acid and sulphuretted hydrogen. Harrogate is now a fashionable watering place, with every accommodation for visitors. The situation of the town is open and airy, and the climate is decidedly bracing.

Gilsland, in Cumberland, has a sulphur spring of some repute.

The Pyrenees is the district _par excellence_ of sulphur springs. _Baréges_ is the most famous of the Pyrenean baths, situated 4000 feet above the level of the sea. Its water, which has a natural temperature of 86° Fahr. to 111° Fahr., contains only 1·657 grains to the pint, of which ·360 grain is sodium sulphide. This becoming decomposed on exposure, forms the sulphuretted hydrogen which gives the character to the spring. These sulphur waters contain a peculiar gelatinous organic substance which has been called barégine, and which has been supposed by some authorities, but on insufficient grounds, to give the peculiar virtue to the water.

Cauterets, in the Pyrenees, 3000 feet above sea-level, with a sulphur water having a natural temperature of 98° Fahr. to 130° Fahr.

Bagnères de Luchon, 2000 feet above sea-level, with a natural hot sulphurous water.

Eaux Bonnes and _Eaux Chaudes_, 2000 feet above the sea.

At _Aix-les-Bains_, in Savoy, one of the springs is strongly impregnated with sulphur.

Aix-la-Chapelle, in Rhenish Prussia, is 450 feet above the sea. The water contains about 30 grains of solid contents to the pint, and is strongly impregnated with sulphuretted hydrogen.

Any water may be used for bathing purposes, and it is almost always the custom for visitors who go to a spring for the purpose of _drinking_ the water, to take some _baths_ as well, the baths often being composed of the same water as that used for drinking. It is not generally believed that there is any particular virtue in baths composed of alkaline waters, such as those to be found at Vichy, nor in purgative waters, like those at Carlsbad, nor in iron waters like those at Tunbridge Wells, Spa or Schwalbach. Hot bathing, however, may be expected to help the effect which it is sought to bring about by taking the water internally, and it has not unfrequently been the case that the effect of drinking has been attributed to the bathing.

It is worthy of remark that, at some places where miracles are claimed to be wrought by the effect of water (as, for example, at Malvern), the water used is remarkable merely for its great purity and almost absolute freedom from mineral ingredients.

It is not a little remarkable that some waters, which were formerly used almost exclusively for _bathing_, are now used almost as exclusively for drinking. Carlsbad affords an instance of this. The word _bad_, when used as an affix, generally indicates that the water is or has been used mainly for bathing. The word _brunn_, or _brunnen_, however, usually implies that the spring has been mainly employed for drinking purposes.

CHAPTER IV.

THE USES OF BATHS.

We do not propose to enter at all fully into the question of the place which baths ought to occupy as remedies for disease; but we shall merely indicate some of the chief conditions for which bathing might reasonably be expected to be of service. It has been generally claimed for baths that they cure everything; and, in fact, the many unfounded assertions as to the remedial powers of hot and cold water, which have been made by professed hydropathists and others, have done much to bring these very useful agents into disrepute.

It proved very puzzling to the acute mind of the author of the ‘Bubbles from the Brunnens,’ that the baths and waters which he encountered in his travels seemed capable of curing everything; and it was difficult to understand how patients whose conditions were in no way similar should apparently derive equal benefit from precisely the same treatment; and perhaps we shall not be wrong in assuming that the very healthy mode of life which is pursued by visitors to baths has much to do with the good results of treatment.

The most common purpose for which baths are used is the cleansing of the skin, and the importance of this, of course, cannot be over-estimated. When we speak of a clean skin we mean a skin with clean pores as well as a clean surface. The indolent and luxurious man, whose skin is spotlessly clean, but whose sense of the proprieties is such that he never indulges in a good vulgar sweat, has not, in reality, so healthy and clean a skin as the navvy, whose myriad sweat-ducts are constantly being flushed by the hardness of his work; but whose skin surface, possibly, is soiled with the various grimy particles with which his labour has brought him in contact. A clean skin is an impossibility without perspiration; and if the necessary perspiration be not brought about by the ordinary business of life, it is advisable to encourage it by artificial means. Hence bathing is more necessary to the man of sedentary occupation than to one who knows the daily luxury of physical exertion. For the purposes of cleansing, the bath should be warm, the skin should be well soaped, and a subsequent thorough friction with a rough towel should be indulged in. This process has the effect of removing the outer layer of the cuticle, of softening the secretion lying in the mouths of the sweat-ducts, and by the action of the heat dilating the blood-vessels of the skin and encouraging perspiration. Its utility and its comfort are so well known that there is no necessity for making any formal remarks thereupon.

Perhaps there is no better form of exercise than that to be found in a good swimming bath, always provided that an open river or the sea is not at hand. The swimmer exercises every muscle in his body; and, if swimming be vigorously kept up, there is nothing which more speedily induces fatigue. For an athlete in training a daily swim ought to be a part of his course of exercise. We wish there were more swimming baths in London than there are. Such as exist are all overcrowded in the summer, and in many of them the ventilation is not of the best. To take violent exercise in a close, badly-ventilated room must be wrong, and we would advise no one to patronise a bath which smells in the least degree stuffy. Swimming should be practised not more than once a day, and about midway between two meals. The bather, at the commencement of his course, should not remain more than five minutes in the water; and if his bath be not followed by a healthy glow, he will recognise that even that is too much for him. The time of the bath may be gradually extended.

The cold bath in the morning is a luxury of which most of us know the value. It cleanses, stimulates, and braces; and, if used in moderation, conduces to health. A word of caution is necessary to those who use their “morning tub” too heroically. The best criterion as to the advisability of continuing its use is the readiness and completeness of the reaction; and, if there is any feeling of chilliness, languor, or want of appetite, with an inability to eat breakfast, it is as well to ask whether, possibly, the cold bath had better be moderated. Persons who suffer from rheumatic pains, or sciatica, or neuralgia, ought also to be careful about continuing a practice which may be too severe for them. It is always easy to add a small quantity of warm water to the bath. There can be no doubt that a daily bath is absolutely necessary for the health of children who are tender-skinned and too young to attend to their

personal cleanliness.

There are certain diseases in which cold bathing is of acknowledged service:--

Foremost among these is _fever_, and it is not too much to say that many lives have been saved by the timely use of the cold bath. The use of it, however, requires great judgment and knowledge, and it is not applicable to every case, and is not without danger. In this country its use is restricted almost entirely to those cases in which the fever runs a very severe course, in which the bodily temperature rises above 105° Fahr., and the patient attains what is technically known as a condition of hyperpyrexia. The use of cold baths in fevers has been known from time immemorial, although it has only attracted the attention of modern physicians during the last ten or fifteen years. The usual method of employing this treatment is to immerse the patient in a bath of about 90° Fahr., or 95° Fahr., and by means of removal of hot water and its renewal by cold, gradually, in about 20 minutes, to reduce the temperature to 60° Fahr. In this way the temperature of the patient may be reduced as much as four or five degrees, and his sufferings are usually very much diminished. Cold bathing cannot be said to _cure_ the fever, but it prevents some of its worst results, and may enable the patient to pass through a trying ordeal unscathed. All forms of fever may, occasionally, be treated with cold baths; but this method of treatment in no case shortens the course of the fever.

Cold bathing is of considerable use in some nervous affections, such as hysteria, St. Vitus's dance, and spasmodic croup. These affections often, if not always, depend upon a depressed condition of health, and a cold bath of short duration (before a fire in winter), and followed by a brisk rubbing, is a very efficient means for their relief.

Rickets is benefited by cold bathing; but for the relief of this and other conditions of weakness the greatest moderation must be observed.

Cold water is sometimes of use when locally applied, and seems to act as a wholesome stimulant to parts which have become stiffened by want of use, such as strained and sprained joints. In some skin diseases benefit will be derived by the use of cold water. This is particularly the case in itching of the skin or _Prurigo_, and _Acne_.

Warm baths are far more generally useful in diseases than cold baths. For the removal of the thickenings around joints, which have been caused by gout or rheumatism or "rheumatic gout," bathing in tepid or hot water is justly considered as a powerful means of alleviation, and as a valuable accessory to treatment by diet and regimen. The hot water of Bath and the tepid water of Buxton have long enjoyed a great reputation for gout and rheumatic gout, and there are many baths on the Continent, which have a reputation, equally high, in the treatment of these affections, such as _Teplitz_, _Gastein_, _Wiesbaden_, and _Wildbad_. The treatment of gout by bathing is usually aided by the internal administration of mineral water, but into this question we are unable to enter, notwithstanding its great importance.

For exudations round joints, which have arisen from causes other than gout and rheumatism, warm bathing is of very great service, as well as in relieving the stiffness and thickenings which sometimes occur as the result of severe wounds.

For _paralysis_ warm bathing is often of great use, provided the cause of the paralysis be a removable one. Formerly, the principal method of treating cases of lead paralysis occurring in the cider counties of the West of England, was the sending of the patient to the warm springs at Bath, and the results were generally very good. There are many forms of paralysis which could not be benefited by treatment with hot water or anything else; but it is impossible, in an elementary treatise, to enter into a question requiring a high degree of medical knowledge for its proper appreciation.

For neuralgia, sciatica, lumbago, and many forms of muscular rheumatism, hot bathing may be employed with advantage.

For Bright's disease of the kidneys, warm baths, vapour baths, and Turkish baths, are all employed with benefit.

An occasional Turkish or hot bath is a very great aid to the well-being of dwellers in cities who get an insufficiency of air and exercise, since it produces an activity of the skin which can only be brought about by such means or by violent exertion.

A common cold may sometimes be cured by means of a Turkish bath. To bring about this result, however, the treatment must be applied in the very earliest stages of the disease, when the slight tension in the head, or a trifling feeling of chilliness, is warning the patient of his coming trouble, and before the running of the eyes and nose has thoroughly set in. A Turkish bath in this very earliest stage of a cold will sometimes cut the disease short, but such a result is, unfortunately, by no means invariable.

Warm baths, as aiding the action of the skin, have been regarded as of some value, when combined with proper diet and regimen, in the treatment of diabetes.

In diseases of the skin warm bathing is occasionally of service. For _psoriasis_ a soaking in hot water has the effect of removing the scales from the body, but it has probably no real curative influence on the disease. In acne, chloasma, and diseases which are fostered by a want of attention to cleanliness, warm bathing is of great service, especially when aided by a liberal supply of soap and the rigorous use of the flesh-brush and rough towel.

Although we are all ready, perhaps too ready, to recognise the great value of water applied externally, we are not always so quick at recognising the evil effects of an excessive use of baths.

Professor Hebra, of Vienna, one of the greatest authorities living on the diseases of the skin, speaks in very decided tones of the occasional harmful action which water exerts upon the skin. “It is,” he says, “almost universally believed that the frequent use of vapour and shower baths, frequent bathing in warm or cold water, frequent washing and scrubbing, are healthful operations which can never do any harm.

“Against this opinion I must enter my decided protest. On the one hand, we know that there are millions of human beings who have never bathed in warm or cold water all their lives long, who, at the utmost, give their hands and face a superficial rinse once a week, and nevertheless enjoy up to old age a state of health which may well be envied. On the other hand, none can prove by statistics that the frequent use of the various kinds of baths protect people from sickness, or that washing in cold water strengthens the body against catarrh and rheumatism and catching cold. So long as bathings are accompanied by a feeling of comfort, and are not followed by any eruptions on the skin, they may, no doubt, be allowed as a pastime, an amusement, an aquatic sport; but whenever the skin thus repeatedly irritated begins to react--as soon as itching, more or less severe, follows; as soon as persistent redness or wheals, or pimples or watery heads make their appearance--it is high time to leave off bathing and washing if we do not wish to produce diseases of the skin, which often take months and years before they disappear, and give the patient unspeakable misery.”

Simple baths do not irritate the skin so much as when combined with shampooing and wet packing and shower-baths, or when a vapour bath is made more efficient by friction and by the various manipulations of the Turkish or Russian bath. The result of such attacks upon the skin are seldom long to wait for. Sooner or later a continual redness appears, followed by burning or itching; then come pimples, boils, and pustules; and though in past times these eruptions were regarded as critical and beneficial we must now look on them in their true light, as simply the injurious results of the action of water.

Hebra has used the warm bath with success in alleviating the pain and misery arising from extensive burns of the skin, and he has also used it for some of the more troublesome of the scaly and itching diseases of the skin. Although he seems more alive than most authors to the evil effects produced by the irritation of water in cases which are unsuited for it, he has, on the other hand, surpassed every one in the extensive and continuous use of warm water. He says, “I began with two hours, then advanced to days, and at last extended the duration of the warm bath from one to nine months. I find that people can eat, drink, and sleep just as well in a continuous warm bath as out of it; that nutrition, respiration, and excretion go on as before.”

Hebra asserts that in the external use of water it is a matter of small moment whether we apply the water hot or cold to the part; that the water soon approximates in temperature to that of the part to which it is applied; and that in this matter the wishes and inclinations of the patient need alone be consulted. With regard to _salt baths_, we may remind the reader that they may be used either cold or hot, and that they may thus be used in almost all those cases (some skin diseases excepted) in which baths of hot or cold water are found useful. When salt is added to the water, the stimulating effect upon the skin is increased, and the bath may be considered by so much the more powerful. Sea water, natural salt waters, and even crystals of sea-salt, or common salt added to ordinary water, have so firm a place among popular remedies that it is almost superfluous to make any formal remarks upon them.

It is perhaps in the treatment of scrofulous affections that sea bathing and salt water have their greatest reputation. The sea-bathing infirmary at Margate is too well known, and its work too highly valued to need any words of approbation from the author of this Primer. It is probable that the inhalation of sea-air has more to do with the successful treatment of scrofula than the bathing in sea water, although we have no wish to cast a doubt upon the efficacy in the treatment of such diseases of a systematic stimulation of the skin.

Dr. Jacob of Cudowa, in Silesia, has made a series of experiments on the power of stimulating the skin which is possessed by various kinds of baths. He has proved that mud and bran baths of the same consistence produce the same alterations in the circulation, which are to be regarded as the real expression of the amount of skin-stimulation. It has been ascertained also that mud baths retain the heat of the bather more effectually than simple water baths. A carbonic acid bath is said to have the greatest stimulating action on the skin; a saline bath the next greatest, and mud and pure water follow next. A carbonic acid bath is also said to have the greatest power of causing general stimulation and excitement. As to the cooling effect of these varieties of baths, Dr. Jacob has noted that a water bath of an hour's duration, and of a temperature of 91·4°, lowers the bodily temperature of a healthy man about ·9°; the mud bath of same duration and temperature 1·5°; the salt bath 2°, and the carbonic acid bath about 2·6°.

Sulphur baths in former times enjoyed a very great reputation in the treatment of skin diseases, gout, rheumatism, and the effects of metallic poisons, especially lead and mercury. There is, however, probably nothing peculiarly beneficial in the sulphur, and the good effect of these baths is due more to the heat of the water than to anything else. Many of the sulphur springs may rightly be regarded as salt waters also, and they have a great power of skin-stimulation, a power which adds immensely to their therapeutic efficacy. The bather in sulphur water is constantly inhaling the vapour of sulphuretted hydrogen, and this fact may have not a little to do with the good effects of the water. A course of bathing at a sulphur spring is generally combined with the internal administration of the water, and it is consequently a very difficult problem to determine whether the internal or external administration of the water has the greater effect in producing the desired cure.

Steel baths, or baths containing iron, have fallen almost entirely into disuse, and any effect which was formerly attributed to the chalybeate water is now with more probability ascribed to the water and its temperature. The change in this respect is scarcely greater than that which has taken place at Carlsbad, where purgative waters, formerly used chiefly for bathing, are now almost exclusively employed for drinking.

The author of the 'Bubbles from the Brunnens' thus describes his feelings while taking a steel bath at Langen Schwalbach, some forty years ago:--

"As soon as the patient was ready to enter his bath, the first thing which crossed his naked mind, as he stood shivering on the brink, was a disinclination to dip even his foot into a mixture which looked about as thick as a horse-pond, and about the colour of mulligatawny soup. However, having come as far as Langen Schwalbach, there was nothing to say but '_en avant_,' and so, descending the steps, I got into stuff so deeply coloured with the red oxide of iron that the body, when a couple of inches below the surface, was invisible. The temperature of the water felt neither hot nor cold, but I was no sooner immersed in it than I felt that it was evidently of a strengthening, bracing nature, and I could almost have fancied myself with a set of hides in a tan-pit. The half-hour which every day I was sentenced to spend in this red decoction, was by far the longest in the twenty-four hours, and I was always very glad when my chronometer, which I regularly hung on a nail before my eyes, pointed permission to me to extricate myself from the mess. While the body was floating, hardly knowing whether to sink or swim, I found it was very difficult for the mind to enjoy any sort of recreation, or to reflect for two minutes on any one subject; and as, half shivering, I lay watching the minute-hand of my dial, it appeared the slowest traveller in existence."

In the delightful book from which the above quotation is taken, no mention is made of the disease, if any, for the relief of which the author underwent the unpleasant ordeal of the iron bath. The reader, however, will have no difficulty in surmising that the good he derived at Langen Schwalbach was due more to the change of air and scene and occupation than to the disagreeable bathing process to which he submitted daily. There is, or has been, a great deal of superstition in medicine, and the public have, or used to have, a surprising amount of faith in nasty medicines. In old dispensatories will be found the records of prescriptions into the composition of which there entered hideous and nameless abominations, and we are very much inclined to think that the lingering belief in steel baths, sulphur baths, and mud baths is but the remnant of a dying faith in nasty prescriptions, and the necessity of doing penance.

CHAPTER V.

A VISIT TO A BATH.

When the doctor's fiat goes forth that his patient is to visit this or that bath for the benefit of his health, far more is implied in the injunction than the mere use of water, whether mineral or indifferent, hot or cold. It means that the sufferer is to leave his usual place of abode, and the climate which may perhaps have been instrumental in working him ill; to forsake the numerous causes of

mental worry and bodily fatigue which may be connected with his occupation or his family cares; to bid adieu for a while to the cook--good, bad, or indifferent--who perhaps has tickled his palate to the ruin of his stomach, and the cellar which has daily furnished those wines which, gravitating to the toes, have necessitated the big boot and the stout staff; to turn his back for a season on all that is implied in the words “good society,” and exchange all these for something else. Whether that exchange will be beneficial or otherwise will depend upon the knowledge of the patient possessed by the adviser--knowledge, not only of his constitution and his ailments, but of his pocket and his inclinations. The man of cultured mind, like Sir Francis Head, whose diary of life at Langen Schwalbach forms so charming a volume, who is able to find amusement in the contemplation of human nature, or of natural phenomena, who

“Finds tongues in trees, books in the running brooks, Sermons in stones, and good in everything;”

whose resources are within himself, will find his recreation everywhere, and provided the place to which he is sent be wholesome, he will get all the benefits which are derivable from change of scene and air. It would be cruel and useless, however, to send the votary of pleasure to a resort where art provides nothing for the amusement of the guests, and equally useless to condemn a man accustomed to a simple country life to mingle all day long in a fashionable crowd, intent on artificial joys. There is no doubt that on the Continent the arrangements for the comfort and amusement of guests visiting a bath are more perfect than they are in this country; and the invalid who crosses the “silver streak” which separates us from the rest of Europe will find a greater difficulty in continuing in that groove of existence which, mayhap, has been prejudicial to him. On the other hand it must not be forgotten that to many persons foreign travel is exceedingly distasteful. There are many who know no language but English, and whose prejudices are so in favour of English manners and customs that they cannot be induced to fall in with Continental habits. We remember seeing a gentleman at a fashionable bath abroad, whither he had been sent for the relief of his gout, who was evidently most grievously bored by the process of cure. He associated with none, dined alone, and day after day partook, in a solitary corner of a restaurant, of a fried sole, a mutton chop, stilton cheese, and a pint of dry sherry.

A man who thus carries his own atmosphere with him, and who persistently goes against the stream, wrapping himself in insular prejudice, will find very little benefit in foreign travel or in change of scene.

There are few bathing places, either in this country or on the continent, where the drinking of water does not hold a position in the “cure” which patients are prepared to undergo, at least equal to the bathing. Drinking of mineral water and bathing go everywhere hand in hand, although at different spas the one or the other method of treatment will be found to preponderate. With the drinking of water we have, as we have before said, nothing, at present, to do; but, although in theory it is easy enough to separate the effects of bathing from those of water drinking, it is found less easy to do so in practice.

What Epidaurus was in the palmy days of Greece when thousands flocked to seek health and recreation at its renowned temple of Æsculapius; what Baiæ was to the luxurious Romans who came to its famous warm springs, impelled equally by fashion and disease; what Bath was when at the zenith of its popularity; such is the Badstadt of the present time. The throng in the town in the height of the season (July and August) is very great, and the crowd of visitors is as fashionable as it is cosmopolitan. Here are German petty potentates, Russian princes, English nobles, and wealthy Americans, by scores; and there can be no doubt that the charm of a fashionable watering-place like this is by many found in the fact that all men are, more or less, upon an equality where there is only one fountain from which they all must drink, and one source in which they all must bathe. The duke, whose pedigree reaches back to the Dark Ages, must equally wait his turn with the merchant whose wealth is of yesterday’s creation; and in waiting-rooms of bath-houses, at tables-d’hôte, and at the brink of healing fountains, blood which is of the bluest tint comes into very close contact with that which is of other shades.

The town of Badstadt is most charmingly situated upon an elevated plateau, some 600 or 700 feet above sea-level, and in the midst of delightful scenery, which is to be found among the mountains which surround the town on every side but one. The mountains are clothed to their summits with pine, and these pine woods are amongst the most favoured places to which the “cure guests” of Badstadt resort. In the depths of the pine forest there is always, even in the hottest day, a refreshing coolness and an invigorating aroma, and to wander here with a book, or a companion and some luncheon, is a most pleasant method of killing the sultry hours of noon. One day is pretty much like another at Badstadt, although here is just sufficient variety to obviate any feeling of irksomeness. What will the fashionable Londoner think when, at six o’clock in the morning, he finds that he can no longer sleep because every one in the hotel is already stirring? There is nothing for it but to go with the stream, to get up and dress oneself (in the nattiest of lounging coats if of the male sex, in the most bewitching of light summer costumes if of the female), and away with the rest of the world to drink the water at the Betsinda Quelle, the most fashionable spring in all Europe. It is not seven o’clock, we

are nearly four hours earlier from our beds than is our wont, the fresh morning air is bracing and delightful, the sun has not yet dissipated the dew, and yet the whole world of Badstadt is alive. Here beneath the trees of the Cur-garten are some 2000 or 3000 fashionables, all sauntering and talking, so that the hum of conversation is audible at a great distance, and forms a not inharmonious obbligato to the music of the orchestra in the Kiosk which is hard by. Few prettier sights than this can be seen or imagined. The avenue of limes offers in either direction, a most attractive vista; the sunlight comes glinting through the fret-work of leaves upon the gravel, creating little dancing shadows and lighting up the many and varied colours of the ladies' costumes; the roses in the neighbouring flower-beds lend their bright colours to give the eye additional pleasure, while their aroma tickles yet another sense; and the ear is pleased by a performance, by an excellent band, of the best compositions of the best masters. The focus, as it were, of all this gaiety is the Betsinda Quelle, and most of the guests may be seen to advance to the edge of the health-giving fountain, which is enclosed in a sunken ornamental basin, and tender a glass for the prescribed dose of the water. The water contains a good deal of common salt and not much else, and is nearly as nasty as sea-water; but it is surprising to see how methodically and with how little fuss the _habitués_ get through their allotted portion. The physician probably said to this or that patient: "You are to drink two glasses of the Betsinda, and you are to walk for twenty minutes after each glass;" and one may see hundreds, who, watch in hand, carry out their directions to the letter. He who frequents the springs regularly will soon recognise that, morning after morning, the same people arrive at the same time, consume the ordained number of glasses and disappear. The majority of these, it must be confessed, do not appear to be very ill, although here and there may be seen some whose faces bear evidence of disease, whose limbs are crippled with gout or rheumatism, and who accomplish the morning promenade with the aid of sticks or crutches, or, in place of walking, perform a cruise upon wheels in an invalid chair. Badstadt is above all things a pleasant place, and everything has been done that money can accomplish to charm the senses and make life agreeable. The notables of society are its chief patrons, and there can be no doubt that the majority of the visitors come here for the season, strange as it may seem, that they may meet the same persons that they have been meeting earlier in the year in the "Row," upon the lawn at Goodwood, or in the salons of Paris. "Good Society," by which term we mean those wealthy and noble individuals who prefer an artificial to a natural existence, annually makes itself ill by attending too assiduously to its duties. Having risen from its bed some eight hours later than the sun; having dined largely every night on a mixture of all that is rich and unwholesome; and having freely partaken with its meals of all manner of liquids other than water; having danced night after night in rooms reeking of androsmia (which is polite Greek for the "smell of humanity"), and rendered stifling by wax lights or gas; having retired to bed just before sunrise, and, in short, having shown an unaccountable dislike for the light of heaven, and an equally unaccountable preference for those wretched and poisonous substitutes which our dark northern latitudes have rendered necessary, Society takes itself to Badstadt to try the experiment of undoing all the mischief which has been brought about by its own folly. The morning promenade is an integral and most important factor in the Badstadt cure; and the potations of salt water have not only a cleansing and "alterative" effect, but they damp the appetite a little, and help to prevent Society from taking too much food. The Badstadt breakfasts are very simple repasts; one cup of coffee and delicious bread, butter is not allowed except to a favoured few who can find some good excuse for being treated exceptionally; eggs are a luxury which the local doctors regard with manifest dislike; and as for the chops, devilled kidneys, fried bacon, bits of fish, cold grouse, dabs of marmalade, and other "necessaries," which Society takes at home, they are not to be thought of.

After the frugal repast of coffee and bread has been disposed of, a novel or the newspaper serves to wile away an hour or so, and then the all-important time for bathing is at hand. The baths are of all kinds here, and are made of mineral water or simple water, according to the fancy of the patient or the prescription of the "Bad-artzt" (as the local practitioners are called). Both before and after the bath the patient scrupulously observes the directions of Hippocrates, and is careful to keep both body and mind in a state of complete rest, so that sufficient power may be left to thoroughly digest the mid-day meal, which the English call luncheon and the Germans dinner. With those who are wise this meal is as simple as it can be made, and consists of a portion of braised or stewed meat, vegetable, and some simple farinaceous pudding. As for wine, half a bottle of weak Rhenish or Moselle is all that is allowed; visitors being especially warned to avoid even the stronger of the Rhenish wines, such as Rüdesheimer or Steinberger, vintages, towards which those English who have well-filled pockets are very apt to gravitate. In the middle of the day the Germans habitually take their heartiest meal, and towards one o'clock a stream sets in the direction of the 'Adler' or the 'König Wilhelm,' where possibly the same sixty or eighty persons meet day after day at the table d'hôte. These repasts are often regulated by the advice of the local physicians, and one great advantage of patronising them lies in the fact that it is impossible to get viands which are at all difficult of digestion, or which are likely to disagree with the waters. After dinner comes an open-air concert beneath the trees, in the garden of the Cur-haus, and the process of digestion is allowed to complete itself in the fresh air, while the ears are tickled by the sound of first-rate music.

For those who wish to read, the salons of the Cur-haus are always open, and every journal of note which is published in San Francisco or St. Petersburg, or any of the intermediate cities, is freely placed at the disposal of the guests. When we say freely placed we mean freely to those who pay the “Cure tax,” a small sum which is levied from all who come to participate in the enjoyments which are provided by the Badstadters for their guests.

The afternoon is devoted to a drive or a leisurely walk to the neighbouring forest; and at six o’clock the English return to dine; and at seven or half-past seven the Germans come home to supper. The _cuisine_ at the Cur-haus, being modelled on Parisian lines, attracts many of the guests who cannot submit to the Spartan _régime_ of Badstadt in its entirety; and there may be seen occupying the small tables on the terrace snug parties of three or four having just one of those very “little dinners” which have been the main cause of that indisposition which has made a “cure” necessary. The evenings are usually occupied by promenading in front of the Cur-haus, and occasionally a display of fireworks, or an illumination is provided. There is a theatre too, at which the best actors and singers appear during the season; but these after-dinner amusements are mostly of short duration, and, as a rule, Badstadt retires to bed not later than ten o’clock.

Thus it will be seen that life at a bath is spent largely in the open air, that the amusements and the routine of each day are regulated mainly with a view to health, that the diet is restrained within the limits of prudence, and that “early to bed and early to rise” is a wise maxim, to which a rigid adherence is expected of all who come in quest of health to the baths and springs of Badstadt. It is not surprising that the Badstadt waters should be regarded as a panacea throughout the whole of Europe.
